The CHAIRMAN, in reply to Mr. VAN LAUN, said that, notwithstanding all the drawbacks incidental to the establishment of an enterprise such as theirs, the original statements made to the shareholders by the Board had been substantiated, for on the basis of the present demand they would earn a good profit. They had been careful to draw the attention of the shareholders to the fact that the requirements of the Company demanded necessarily additional capital, and if they were to do justice to their district that capital must be found.

The MANAGING DIRECTOR, in further reply to the same gentleman, said that the Company held Parliamentary powers for 42 years on terms which were exceedingly favourable—terms which were obtained by the early London companies which were not being obtained now by applicants for Provisional Orders from the country. They had a business, therefore, with a long Parliamentary tenure, and that business was every day improving. He was quite certain that a searching examination of the accounts would convince anyone that there was no fear of its ever retrograding. Their works had been visited by people from all parts of the country, and were acknowledged by everyone technically versed in such matters to be the finest extant for electrical distribution. He added that, pending the building up of the Company's business, the Directors had decided to forego their claims to Directors' fees.

The motion was then agreed to *nem. con.*

The CHAIRMAN next moved, and Mr. HAMMOND seconded, the re-election of the retiring Directors, Mr. W. Page and Mr. R. A. Germainò, which was also agreed to unanimously.

On the motion of Mr. WHITEHEAD, seconded by Mr. BEEVOR, the auditors, Messrs. Theobald Bros. and Miall, were reappointed, and the proceedings terminated with a vote of thanks to the Chairman.

A. U. Alcock Electric Light and Motive Power Company, Limited, (Melbourne, Australia).

The third half-yearly meeting of this Company was held at Melbourne, Victoria, on Wednesday, April 29th, Mr. W. J. Mountain, Chairman of the Board of Directors, presiding.

The report and balance-sheet, which had been previously circulated amongst the shareholders, were taken as read. The Directors, in the

Digitized by Google

report, congratulated the shareholders on the satisfactory result of the past half-year's proceedings. The profits amounted to £490. 2s. 8d., which, considering the excessive cost of fuel during the late strike, and the fact that the price of lighting was not raised to their consumers, must be a cause of satisfaction. Due allowance had been made for depreciation of plant, and, after providing for one-fifth of the balance of the expenses incidental to the formation of the Company, there was a credit balance of £678. 8s. 7d. to the profit and loss account, which the Directors recommended should be carried forward to next half-year. The profit and loss account did not include the charge for interest. It had been considered that, as the overdraft was caused by the erection of the building and the purchase of the machinery, the amount charged by the bank for interest while the building and plant were in progress, should be charged to those respective accounts. A third issue of 15,000 shares had been made to complete the buildings and machinery of the central station at Richmond, of which 7,000 had been taken by the shareholders, and the Directors were confident of being able to dispose of the balance of 8,000 to the public. The machinery for supplying the incandescent light in South Melbourne was started on April 11th, and promised to be a great success. The Company had obtained "the exclusive right for Victoria to a meter that had just been invented;" and the Directors, in conclusion, considered the prospects of the Company as most assuring.

The CHAIRMAN, in moving the adoption of the report and balance-sheet, congratulated the shareholders on the favourable results which had attended the Company. The plant at present in use was only small, and the returns were very favourable for the size of the machinery, considering that £200 extra had to be paid for fuel in consequence of the late strike. Although the Company had only been in existence 18 months, the Directors considered themselves thoroughly justified in launching out on a much larger scale, so as to be able to supply Melbourne and the suburbs. They had therefore purchased a large block of land at Richmond on which they had erected a section of a central station. From its position the central station was most easy of access from Melbourne and surrounding cities and suburbs, of which the Company anticipated lighting a considerable proportion. The Company had also secured the patent of a meter which, in every respect, had proved satisfactory. Instead of selling their electricity by contract they would be able to sell it to their customers by meter, and the consumers would only have to pay for just what they consumed. There was an increased demand for the Company's light, and the Company would have no difficulty in supplying all the demands that could be made upon them. The Company were also moving in the direction of trying to obtain an Act of Parliament which would legalise them as a company, and confer advanced rights on them and on their consumers. There was a very influential directory of the Company, and they took the greatest interest in furthering its progress.

Mr. C. FLESCH seconded the motion, and it was carried unanimously.

Messrs. C. M. Holmes and W. Cook were re-elected auditors, and a vote of thanks was passed to the Directors for their past services.

West African Telegraph Company (Limited).

The following is the report of the Directors of this Company to the sixth ordinary general meeting of shareholders, to be held at Winchester House, E.C., on Thursday, July 2nd, at 12:30 o'clock.

The Company's revenue for the 12 months ended December 31, 1890, amounted to £68,377. 19s.; against which £21,685. 13s. 7d. is charged for ordinary expenses £4,788. 14s. 3d., for expenditure relating to repairs of cables, &c., and £639. 8s. 5d. for income-tax—leaving a balance of £41,264. 2s. 9d. From this amount is deducted £23,693. 13s. 4d. (being for interest on debentures £14,027., and for sinking fund £9,666. 13s. 4d.), leaving a balance of £17,570. 9s. 5d., out of which the Directors have placed £6,015 19s. 5d. to the general reserve fund.

The shareholders have received for the six months ending June 30, 1890, an interim payment amounting to 4s. per share, and the Directors now recommend a dividend of 6s. per share, making 5 per cent., free of income tax, for the year ended December 31, 1890; which, with the appropriation to the general reserve fund of £6,015. 19s. 5d., will absorb the balance standing to the credit of the revenue account.

The repairs on the Bolama-Bissao cable have caused an expenditure of £2,092. 9s. 1d. The work was well and promptly done. In view of future repairs of this character, it has been deemed expedient to join with the affiliated companies in obtaining the services of a maintenance ship, which will be available at all times for similar work. This involves a cost of £2,500 per annum.

The several sections of the Company's system of cables are now in good working order.

The traffic, under the arrangements made with the other companies which form a cable communication around the continent of Africa, continues to give good results to this Company.

The Directors who retire by rotation are Sir Henry C. Mance and John Denison Pender, Esq., who, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., also offer themselves for re-election.

NEW COMPANIES REGISTERED.

AGENCE DALZIEL (LIMITED).—Registered by Burton and Company, 37, Lincoln's-inn-fields, with a capital of £60,000, in £10 shares. Objects: to acquire, as regards France, its colonies and dependencies, the business heretofore carried on by Dalziel's Cable News Agency (Limited), in accordance with an agreement expressed to be made between Dalziel's Cable News Agency (Limited), of the one part, and the Company of the other part, and to carry on generally the business of a news agency for the receipt and supply of news and information of all kinds; also to carry on the several businesses of news paper proprietors, printers, publishers, stationers, telephone, telegraph, and electric light engineers, &c., &c. The first subscribers are:—D. Dalziel, 222, Strand; H. King, 18A, Exchange-buildings, Liverpool; M. Hallett, Beech, wood, Slough; H. F. Jackson, 31, Harrington-gardens, S.W.; W. L. Whittaker, 65, Warwick-road, W.; R. L. Devonshire, 1, Frederick-place, Old Jewry; W. Smith, 9, Providence-terrace, Earl's Court. There shall be not less than two nor more than seven Directors. The first are the first four subscribers to the Memorandum of Association. Qualification, £10. Remuneration, £500, with an additional 10 per cent. after payment of 10 per cent. dividend. Registered June 19th.

ELECTROLYTIC CAUSTIC SODA AND CHLORINE TRUST (LIMITED).—Registered by Walter Webb and Co., 23, Queen Victoria-street, E.C., with a capital of £10,000, in £10 shares. Object: to carry into effect an agreement expressed to be made between James Charles Richardson of the first part, Trevenen James Holland of the second part, and the Company of the third part, for the acquisition of certain patents relating to improvements in the electrolytic production of caustic soda, caustic potash, and other products from their salts, and for improvements in apparatus to be used for electrolytic purposes, and to develop, improve, and bring into public use the said inventions. There shall not be less than three nor more than seven Directors. The first are G. R. Tyler, C. E. Green, R. C. Baxter, R. Vogan, Colonel T. J. Holland, C.B., and J. C. Richardson. Qualification, £500. Remuneration to be determined in general meeting.

LODDINGTON IRONSTONE COMPANY (LIMITED).—Registered by Jordan and Sons, 120, Chancery-lane, W.C., with a capital of £50,000 in £10 shares. Objects: to acquire iron, coal, or other mines in Great Britain, and to carry on generally the several businesses of coal owners, coal merchants, coke merchants, ironmasters, iron founders, brass founders, wood and metal workers, metallurgists, chemical and mechanical engineers, &c.

JOHN LORD AND SON (LIMITED).—Registered by Pritchard, Englefield, and Co., Painters' Hall, E.C., with a capital of £15,000 in £5 shares. Object: to carry into effect an agreement, made June 12th, between John Lord of the one part, and Henry Wallwork of the other part, for the acquisition now carried on by the said John Lord, at Springfield Wire Mill, Leyland, Lancashire, and to carry on generally the business of a wire manufacturer in all its branches. Registered without Articles of Association.

D. STEUART AND CO. (LIMITED).—Registered in Scotland, with a capital of £100,000 in 10,000 shares of £10 each. Object: to adopt and carry out an agreement, dated 10th inst., between Duncan Steuart and Co. and Mr. Duncan Steuart, the sole partner of that firm, to purchase the property, effects, and business of the firm of Duncan Steuart and Co., as carried on by them at London-road Ironworks, Glasgow, and elsewhere, as engineers; millwrights, boiler-makers, coppersmiths, founders, and general merchants, and to carry on the business of iron and steel manufacturers, and manufacturers of machinery of every description.

CITY NOTES, &c.

ANGLO-PORTUGUESE TELEPHONE COMPANY.—Coupons No. 7 of the First Mortgage and No. 2 of the Second Mortgage Debentures of this Company will be paid, less income-tax, by the Alliance Bank, Bartholomew lane, on and after the 1st prox.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the past week amounted to £5,628.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The traffic receipts of this Company for the past week amounted to £721. The aggregate receipts for the half-year to date are £18,500.

MANITOBA ELECTRIC AND GAS LIGHT COMPANY.—Messrs. Robert A. McLean and Co. will, on and after July 1st next, pay the half year's interest, due on that date, on the Six per Cent. First Mortgage Debentures of this Company.

SOCIETE GENERALE DES TELEPHONES.—The report submitted to the shareholders at the annual general meeting, recently held in Paris, showed a profit for 1890 of 1,012,698fr., out of which it was proposed to pay a dividend of 18fr. per share, to add 33,072fr. to the reserve, and to carry forward 79,625fr. Surprise was expressed by some of the shareholders at the smallness of the dividend, it having been expected that 30fr., or at least 27fr. 50c., per share would have been declared; but the Directors' recommendation was eventually adopted.

TELEPHONE COMPANY OF AUSTRIA.—Coupon No. 13 of the Five per Cent. Debentures of this Company will be paid, less income-tax, by Messrs. Martin and Co., Limited, 68, Lombard-street, E.C., on and after the 1st prox.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The coupons due June 30th on the debentures of the above Company will be paid by Messrs. Barclay and Co., Lombard-street. Coupons must be left three clear days for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—Application has been made to the Stock Exchange Committee to allow 5,324 additional shares of this Company (Nos. 92,048 to 97,371) to be quoted in the Official List. The traffic receipts of this Company for the week ended June 19, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,984.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FACTORY.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70, Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 685.—Vol. XXVII. FRIDAY, JULY 3, 1891. Price Fourpence.

NOTES.

At the last meeting of the Physical Society, Prof. Ayrton read a Paper, by Mr. Mather and himself, on the construction of non-inductive resistances. These resistances are much needed for alternate current testing, as, in every method of measuring the power supplied by varying currents, it is assumed that some portion of the circuit is non-inductive. For such purposes a conductor is required, the current taken by which is always proportional to the voltage applied to it, whether the volts be high or low, steady or alternating. The objection to liquid resistances is their want of constancy, and wire resistances, if wound spirally, appear to possess enough self-induction to introduce considerable errors into the measurements. The authors of the Paper have succeeded in constructing resistances whose inductance cannot be measured by the secohmmeter, the most sensitive instrument at their disposal; and they have also pointed out a simple way of making resistance coils suitable for strong currents, in which the self-induction is so diminished that the errors introduced thereby are much smaller than those caused by the use of the best instruments employed in practice.

At the same meeting, Mr. Vernon Boys showed a number of delicate electrometers, which he has recently devised, and in which great sensibility has been obtained by making the various parts as small and light as possible, and by reducing the controlling force to a minimum. Success in this direction is only possible after the elimination of all extraneous disturbing forces. The most ordinary electrometer is in one sense a very delicate instrument, the forces brought into play being much smaller than in a galvanometer of the same style of workmanship. The only limit to its sensibility is imposed by external disturbances, such as those caused by viscosity in the suspending fibre, which make their presence apparent when the controlling force is sufficiently reduced. By using a fine quartz fibre, both as a means of suspension and as a torsional control, much of the uncertainty due to extraneous effects is got rid of, and Mr. Boys has succeeded in making instruments more than a thousand times as sensitive as those of the ordinary type, and without any loss of reliability in use.

The aim of Mr. Boys was not to produce instruments of a commercial type, but to find out how sensitive they could be made. He has succeeded admirably, and the production of an instrument which will measure with certainty a small fraction of a volt when the needle is only charged to the potential of contact of two metals, is a most remarkable achievement. We already possess in the capillary electrometer, an improved form of which we describe in this issue, an exceedingly sensitive instrument. It is, however, useless for the measurement of, say, 100 volts, and cannot be altered so as to be applicable for such purposes. Mr. Boys's instruments, however, appear to be far more hopeful in this respect, although the moving parts are so light that no sort of pointer could be used except the mirror and ray method employed with ordinary reflecting instruments. It should be noticed that Mr. Boys started to compete with the ordinary electrometer under a handicap of 2,000 or 3,000 to 1; that is to say, while it is usual to charge an electrometer needle to some 2,000 volts or more, he has restricted himself to the contact difference of 0·8 volt. His success is to be attributed to no new application of forces, but merely to attention to structural details, among which the use of the quartz fibre plays the most important part. In one of these instruments the fibre is only 1in. long, while the period of swing is 35 seconds, and might be arranged to be one minute.

A new departure is being made in the examinations of the Finsbury Technical College, which institution is nothing if not practical. The new examiners, Prof. S. P. Thompson and Mr. G. Kapp, propose to set no questions requiring mathematical knowledge, beyond that of quadratic equations, and of the simple trigonometrical quantities, sine, cosine, &c., and the ability to plot values in the form of curves. So far, there is nothing very original, but the candidates are strongly recommended to learn the use of the slide rule, and should bring them to the examination. Greater accuracy in working out examples than can be obtained by the use of the slide rule is not required. This, for an engineering examination, is a thoroughly sensible idea, and is one which has already been tried at Hanover-square. In the Honours Grade, the student may, during the examination, use an electrical engineering pocket book, but if he avails himself of this he must state the title of the book on his answer paper, and in his answers give references to the pages of the book he has consulted. This is an excellent move, but there is no reason why it should stop at pocket books. In after life the engineer never dreams of trusting to his memory for figures and formulæ if the job in hand be of any importance; he has quite enough to do in working out the problems and in keeping the practical requirements and precautions in mind. Examinations being, unfortunately,

Digitized by Google

jobs of considerable importance to many young men, it seems fitting that they should be arranged, if possible, to resemble the work for which, it is to be presumed, their training has prepared them.

We print in this issue an account of a valuable investigation by Prof. Hertz on the mechanical actions of electrical waves. As with all the previous experimental work of the celebrated scientist, the apparatus employed is of a very simple character, so much so, indeed, that the precision of the results obtained is very remarkable. The research brings out more strongly than ever the great complexity of the actions going on within the dielectric. The phenomena of ordinary alternate currents are at present more than sufficient to tax the powers of electricians, while currents having a frequency as high as ten thousand per second, such as have been used by Tesla and Thomson-Houston in America, give rise to effects which at present defy explanation. The currents accompanying electric oscillations are, however, of much higher frequency, and the phenomena accompanying them are more complex still. The oscillations of electric and magnetic force are closely dependent on one another, like the undulations of potential and current which occur with ordinary alternate currents, and hence the difficulty of separating their effects. Prof. Hertz wished to detect the action of the waves on small isolated bodies, in order to obtain results which could not be explained by any theory of action at a distance. In this effort he was, unfortunately, unsuccessful, owing to the minuteness of the forces called into play. At the same time the phenomena of interference, which his previous work has so conclusively demonstrated, form the most convincing proof of the theory that the forces in the ether are propagated gradually from place to place by the action on each other of contiguous portions of the medium.

In some comments on the electric lighting of Cambridge, in our last issue, we stated erroneously that Prof. Garnett was connected with the Newcastle Electric Lighting Company. We learn from Prof. Garnett that, except that the mains of this Company are connected through a transformer, and, therefore, presumably through the ether, with his lecture table, he has no connection of any kind with this or with any other commercial business. We are very glad to correct this statement, which was founded on a verbal misunderstanding as to some tests which he has been making, and to add that Prof. Garnett has declined to undertake the position of superintending engineer to the Cambridge Town Council. He will confine himself to making certain tests of plant, and acting generally in a consultative capacity.

An official communication was made, some three months ago, by the German Government, through the Foreign Office, requesting that "Mr. Preece, Postmaster-General," Dr. J. Hopkinson, Prof. Ayrton, Prof. S. P. Thompson, Dr. Fleming, and Mr. Kapp, might be appointed to serve as delegates for the British Government at the conferences to be held at the Frankfort Exhibition. This request was duly transmitted by the British Government to these gentlemen, accompanied by the observation that, as there were no funds, the delegates would have to go at their own expense. All these gentlemen, we understand, accepted, and were requested to present themselves last Monday for a week's duty, and, further, attend from August 5th to September 30th. It appears that they are simply wanted as jurymen, and one of them asks pathetically what he has done that he should be condemned to seven weeks hard labour at his own expense.

Royal Institution of Great Britain.—The general monthly meeting of the above will be held on July 6, at 5 p.m.

Institution of Electrical Engineers.—A *conversazione* in connection with the above will be held on Monday next, at the Institute of Painters in Water Colours, Piccadilly, at 9 p.m.

Electric v. Horse Cars.—According to the President of the West End Street Railway Company of Boston, electric traction means to that Company a saving of 21 per cent., the cost per electric car mile being 26 cents, as against 33 cents for horse cars.

Long Telegraph Lines.—India can boast of some lengthy telegraph lines, as will be seen by the following figures relating to the six longest:—Calcutta-Kurrachee 1,727 miles, Calcutta-Bombay 1,343 miles, Calcutta-Madras 1,178 miles, Calcutta-Rangoon 1,003 miles, Bombay-Kurrachee 838 miles, Bombay-Madras 794 miles.

Young v. the American Telephone Company.—Mr. Justice Kekewich, on the application of two of the defendants (the American Telephone Company and Mr. Mason, the president of the Company), stayed all further proceedings in this action, on the ground that they were frivolous and vexatious, and that the matter had been disposed of in two previous actions.

Electric Lighting in Belgium.—The following are the number of lamps connected up to central stations in five of the principal towns in Belgium:—

Town.	Arcs.	Incandescents.
Brussels	544	9,507
Antwerp	240	1,481
Ghent	220	4,931
Liege	384	2,040
Verviers	665	2 423

Output of Copper.—The production of copper in Chili during 1890 amounted to 26,300 tons. For the present year it is expected that, in consequence of the civil war, the output will only reach about 16,000 tons. The diminution in the production during the first three months of this year was not very serious, being only 1,513 tons less than in the corresponding period of 1890.

Obituary.—We regret to announce that on Saturday morning Mr. Mackenzie, the Secretary of the General Electric Power and Traction Company, was drowned in the Thames at Hampton while bathing with Mr. Clarke, who was on a visit to him at that place. Mr. Mackenzie was seized with the cramp soon after plunging into the river from one of the islands, and Mr. Clarke himself was almost drowned in trying to save him. Mr. Mackenzie was unmarried, and only 37 years of age.

Improvements in Fusible Cut-outs.—Mr. A. H. Walton writes to inform us that Messrs. Mavor and Coulson's method of wiring is in a great measure covered by his patent No. 5,233 of 1880. He has forwarded us a copy of the specification, which describes fuse blocks held by springs and provided with brass caps to protect the fuse from abrasion. If Mr. Walton can uphold his patent we think that his first claim is of considerably more importance. It runs as follows:—"In electrical circuits a contact bar for any number of fuses, this contact bar to form a point of distribution."

The Junior Engineering Society.—At the last meeting of this Society, a Paper on "Electrical Storage Batteries" was read by Mr. H. B. Varley, A.I.E.E. The author dealt with the capacity of cells and methods of ascertaining their electrical condition and their grouping; the three chief disorders to which they were subject, viz.: buckling of plates, sulphating, and reverting, were touched upon, their causes and remedies being discussed at length. The weight of batteries, their cost, and

Digitized by Google

descriptions of some recent forms of cells, the Electric Construction Co's., Reckenzaun's, Crompton's, Howell's, and Drake and Gorham's, concluded the Paper.

A Substitute for Platinum.—Under the guise of "a method of amalgamating glass with other metals than platinum," a sensationally worded Dalziel telegram attributes to Captain Walter, lecturer at the Military Academy of Vienna, "an invention which has been patented in every country in the world. It will effect a revolution in the manufacture of electric lamps, which will be immensely cheapened by it, as the use of platinum will be entirely discarded." Captain Walter states (according to Dalziel) that his invention will cheapen the manufacture of lamps by 100 per cent., while breakage will not hereafter amount to 5 per cent.

Mediterranean Submarine Cables.—The Italian submarine cable vessel "Città di Milano" has lately laid for the Spanish Government a cable from Almeira to the Spanish African fort of Melilla, not far from the Algerian frontier, the length of which is 76 miles. This cable is now being used. The same vessel is at present engaged in laying a cable in the Straits of Gibraltar, between Ceuta and Tunora, also for the Spanish Government. A connecting line between Tunora and Algeçiras will subsequently be established. A cable will immediately be laid between Tarifa and Tangier, so that Gibraltar will be surrounded by a network of telegraph lines. It is stated that the French Government purpose laying a line at once—a land line between Melilla and Némours, in Algeria—so as to establish direct communication through Spain between France and her African possessions. A grant of 5½ francs for cables between Marseilles and Tunis and Marseilles and Oran was agreed to by the French Chamber on Wednesday last.

Reduced Cable Rates.—The Eastern Telegraph Company notifies that several important reductions of tariff, which were arranged at the International Telegraph Conference of Paris, will come into operation on 1st inst. The rate to Spain will be reduced to 4d. per word, Portugal and Gibraltar to 4½d., Canary Islands to 10d., Malta to 6d., Greece to 7d., Turkey to 6½d., Penang to 5s., Singapore to 5s. 9d., Java to 6s., and Sumatra to 6s. 6d. per word. The rates to South and West Australia, Victoria, Tasmania, and New South Wales were very considerably reduced on May 1st last under a guarantee of the Colonial Governments. As neither Queensland nor New Zealand joined in this guarantee, the rates to those Colonies remain unaltered; but, on the 1st proximo, they will both be reduced by 4d. per word, being the amount of the reduction made in the Indian transit rate at the recent Telegraph Conference. In addition to the above, the Post Office notify the reduction of rates to Austria, Hungary, Italy, and Switzerland to 3d. per word; to Sweden to 4d. per word; to Norway, 3½d.; to Russia, 5½d. The rate to Senegal is also reduced to 1s. 6d., and to Singapore to 5s. 9d.

The Society of Arts.—Mr. Thomas Howard, who died in 1872, bequeathed to the Society of Arts a sum of £500 for the purpose of presenting a prize to the author of a treatise on motive power. The prize having on several occasions been offered without any practical result of value, the Council considered that the most useful way of dealing with it would be to invite some eminent authority on the subject to deliver a course of lectures before the Society on a subject coming within the terms of the trust, on the understanding that the lectures should afterwards be published as a treatise on the subject. The result of this was that Mr. Anderson delivered, in 1884-5, the valuable course of lectures which were afterwards re-published under the title of "The Conversion of Heat into Useful Work." Since that time the interest of the fund has accumulated to a sufficient extent to allow the Council to repeat their action, and they have accordingly invited Prof. Unwin to deliver, during the next Session, a course of lectures on "The Generation of Power at Central Stations, and its Distribution therefrom." These lectures will afterwards be published, to form a treatise on the subject.

Destructive Thunderstorm.—A thunderstorm of unusual severity passed over a large portion of England and Wales on Wednesday and Thursday. The spire of St. Saviour's Schools, Liverpool, was struck and considerably damaged. Mr. Alfred Bowen, the head master, says that he observed what appeared to be a great ball of fire descend from the clouds on to the school tower; the whole building was shaken. A mansion near Abergavenny was struck, and the lightning, after breaking the roof, caused serious havoc in the drawing room, where a marble mantelpiece was torn from its place, and part of the furniture destroyed. At Crewe the chimney of a cottage was struck. The lightning entered the house, displacing the fire grate, mantelpiece, and windows, and hurling them together into one mass of *débris*. The yard wall was knocked down and large fissures also appeared in the walls of the house. At Church Coppenhall, near Crewe, a flash of lightning struck the high road near the Church House farm and bored two large holes in the hard macadam, eight feet apart and several feet deep. At Bristol and Clifton two houses were found to be on fire through the bursting or melting of gas pipes and the gas igniting. In each case, however, the fire was extinguished before very serious damage was done.

Telephones and Tramways.—Writing to the *Birmingham Daily Post*, Mr. Frederick Brown says that he has returned from a special visit to America, made for the purpose of inspecting the electric tram systems there, and thinks that the effect of the heavy current on the telephones is over-estimated. In one city, where there had been an attempt on the part of the Telephone Company to stop the introduction of the "electric road," as the Americans term it—and which attempt, by the way, had failed—special means were taken by the Tram Company to notice the effect of the heavy current on the telephone lines. This was done by setting various people to speak to the Telephone Exchange, and then to each other, at the time that the different cars commenced running; and the effect was so little that the telephone *employés* were not aware that the cars were running until their attention was called to the fact, and six cars were out on the streets. The case has been tried in many of the States in the Union, and has, when carried to the higher courts, if not earlier, always gone in favour of the Tramway Company, on the ground that the streets were intended for traffic; and if this can be facilitated by the use of electricity, a small minority of users, like the telephone subscribers are in comparison to the travelling public, must do the best they can for themselves, either by submitting to the slight inconvenience or by running metallic circuits.

A Thermo-Electric Measurement of Steam Condensation.—A new method of studying condensation in steam-engine cylinders has been tried by Prof. E. H. Hall, of Harvard. The object of the investigation was to trace the changes in temperature, and therefore the passage of heat through the sides of the cylinder, by finding the temperature at a particular depth in the iron at a certain instant corresponding with a particular position of the piston. A series of plugs were constructed, each having a hole drilled through it axially, and being provided with a disc of iron at the end. To the centre of the disc a rod of nickel was carefully soldered, making a good joint less than a thousandth of an inch thick. This joint acted as a thermo-electric couple, and a pair of wires of iron and nickel were led to and joined in a pot of melted paraffin. The temperature of the paraffin could be easily regulated and determined, and made to balance the temperature of the junction in the plug. A galvanometer and contact maker were placed in the thermo-electric circuit, and contact was made at a definite point in the stroke, the contact lasting for about one-sixtieth part of a revolution. By using plugs with discs of different thicknesses from half a millimetre to two millimetres, the changes of temperature could be determined, and by plotting curves corresponding to the slope of temperature at opposite points in the stroke, the area between them representing the amount of heat given up to the metal of the cylinder wall could be determined. No great accuracy was arrived at, but the idea is promising.

Gas in Manchester.—At the monthly meeting of the Manchester City Council, on Wednesday next, the Gas Committee will present to the Council their report for the year ending March 31st last. The Committee state that there are 12,076 public lamps in the city, of which 1,420 are of the improved pattern, and 120 lamps are now fixed in dark courts and pas-

Digitized by Google

sages. The total value of the gas consumed in public lighting was £22,386. Notwithstanding the increased cost of labour and materials, and the reduction in the price of gas in the recently incorporated townships, the financial results of the year's working have been satisfactory, and the profits realised have considerably exceeded anticipation. The total revenue of the gas department from all sources was £488,425, being £54,073 more than last year. The gross profit for the year was £97,276, and, after paying the usual fixed charges for interest, sinking fund, and providing for street lighting, the net profit amounts to £47,545, out of which there has been paid to the city fund £10,000, the adverse balance of £26,277 has been cleared off, and the sum of £11,268 carried forward to renewals account. The Provisional Order for the supply of electricity within a certain prescribed area of the city has been obtained. The Committee have visited a number of important electric installations in London and elsewhere, and have been in communication with several eminent electric engineers for advice and suggestive reports. When these reports are to hand, and have been examined and decided upon, the recommendations of the Committee will be submitted to the Council. The Committee assure the Council that there will be no avoidable delay in making this illuminant available to the public.

University College Engineering Society.—At a *conversazione* held in University College, London, on Tuesday, June 30th, the above Society gave an exhibition of machinery, instruments, models and drawings, in the Engineering Laboratory. The temporary electric lighting was undertaken by the Keys' Electric Company, of London. The light was given by four arc lamps, and an electrolier with six incandescent lamps; the necessary current being supplied by one of the firm's 10-H.P. dynamos working at 110 volts, and running from a Crossley gas engine, indicating 8·H.P., at 1,250 revolutions. The firm also lent a very complete exhibition of electrical appliances. Messrs. Siemens Bros. and Co., and Messrs. Ferranti also gave a very interesting display of electrical instruments, as well as their electric cables. There were several steam engines, a Worthington pump, a small alternate current dynamo, and a model of Brotherhood's three-cylinder engine and pump in motion; whilst numerous models and photographs of Joy's valve gear, Giffard's injectors, Kennedy's water-meter, brick-making machine, torpedo, Holden's liquid fuel injector, Donkin's sprung piston rods, gas exhauster, and four-way valve, Sulzer's valve gear, Hero, Savory, and Newcommen engines, a cylinder of Robey engine with automatic valve gear, represented various branches of mechanical engineering. The laboratory testing machine, capable of exerting a pull of 100,000lbs., was shown, and the method of testing demonstrated, numerous tests in tension, compression, shear, and bending being displayed. The method of testing cement was fully illustrated. The engineering laboratory formed a centre of attraction throughout the evening.

Edison as a Witness.—The free-and-easy style of taking evidence under commission in the United States gives a witness a fair chance of doing himself justice. We never know how to take Mr. Edison, and leave our readers to judge what he really meant by the following answers:—

Q. You recognise the fact, do you not, that in this art of incandescent lighting there is a certain practical relation existing between the size and proportions of the incandescent burner and the character of the conductors employed to carry the current to the lamp?—A. That depends upon what system you use.

Q. I assume, and ought to have said in my question, that the lamps are to be arranged in multiple arc?—A. There is no such relation.

Q. Do you consider yourself the discoverer of that relation?—A. I do not consider myself the discoverer of Ohm's law, and Ohm's law will explain all things that have been done, and it will probably explain everything that will be done in the next thousand years, in electricity.

Q. Is that the best answer that you can make to the question?—A. I don't like to be drawn in as an expert; I am not an expert on the question of words. I will answer questions of facts, but I do not like to expert.

Q. It does not occur to me that I am examining you as an expert on this matter; I simply ask you whether you consider that you are the person who discovered the relation that exists between the size and proportions of the burner of an incandescent lamp and the character of the conductors employed to convey the current to such lamp when the lamp is being used in multiple arc?—A. I do not know whether I am or not in relation to an incandescent lamp. Ohm's law did not mention incandescent lamps. It is a broad general law. I think I have already stated a sufficient answer.

Q. I will put this question, then: Did not you know, as a matter of inference from Ohm's law, at the time when you began your experimentation with incandescent lamps, that with a given size of conductor it would be necessary to give the individual lamps a higher resistance if they were to be used in multiple arc than would be necessary if they were to be used in series?—A. It is not necessary in applying Ohm's law at all, but when you bring in the commercial element in connection with that law, then it is; the fact of the matter is that at the time I experimented on the incandescent lamp I did not understand Ohm's law.

Q. Do you mean that you did not know the formula of Ohm's law at that time?—A. No, sir; I did not know it.

Q. When did you first get knowledge of Ohm's law?—A. It may seem strange for me to state that I do not really understand Ohm's law to-day.

Q. I do not ask you whether you understand Ohm's law, but when did you first know of this law?—A. I have heard of Ohm's law for the last 20 years.

Q. What do you mean by saying that you did not know Ohm's law at the time you began experimenting with incandescent lamps?—A. I mean to say that I did not understand Ohm's law. I do not understand Ohm's law now, and, moreover, I do not want to understand Ohm's law. It would prevent me from experimenting.

The Jamaica Exhibition.—News received from Jamaica, says a Dalziel telegram to the *Times*, under date June 15, indicates a feeling of dissatisfaction among the people, largely arising from the financial failure of the recent exhibition, and partly from other causes that have combined to make that failure more conspicuous. That the latest statement made public by the general manager of the affair shows a cash loss of considerably over $100,000 is certainly bad enough, but as that falls only upon a few wealthy men, who guaranteed any deficiency before the project was fully launched, it does not seriously interest the people generally. The cause of the popular resentful feeling is the fact that, while Jamaica imported a manager from England and placed the matters connected with the exhibition unreservedly in his hands, England took no interest in the event, and made no efforts to aid its success. The absence, also, of any personal marks of distinction from the Home Government for the promotion is severely commented upon. In reply to this, Sir Henry Blake strongly protested in the *Times* of Monday. He apparently admits the cash loss of £20,000, but, quoting the statement that it falls only upon a few wealthy men, he asks, "where, then, is there room for the alleged feeling of dissatisfaction?" He goes on to say that not alone did the Imperial Parliament vote £1,000 towards the expenses of the exhibition, but the Queen lent to the Commissioners portraits of Her Majesty and of the Prince Consort. English manufactures were well represented in the English court, and secured several diplomas of honour and gold medals, and two C.M.G.'s were conferred. He adds that the exhibition has increased the revenue of Jamaica last year by over £60,000; extended trade relations; improved local business; stimulated production; cemented all classes by bringing them together to work for a common object; taught self-reliance; advertised the West Indies, and shown to hundreds of foreign visitors that they could live in Jamaica for months without even hearing the name of yellow fever; while the fact that out of the 304,000 people who, during the three months of its duration, visited the exhibition, there was not a single arrest for drunkenness or disorderly conduct spoke conclusively for the general respectability of the population. To call an exhibition giving such results a financial failure, says Sir Henry Blake, is simply an abuse of language. Lord Newport confirms Sir Henry Blake's letter, and adds that he believes that the exhibition was never expected to be a financial success, which he thinks makes all the more creditable the untiring energy and exertions of Sir Henry and Lady Blake, to whom in a great measure were undoubtedly due the pleasure and benefit derived by the thousands of natives. The *Electrical Engineer* of New York, describing the Thomson-Houston plant of the Jamaica Electric Light Company, says it deserves mention that the Company was able to render valuable service in assisting to light up the recent Exhibition. An English concern that had contracted for lighting the Exhibition was unable to live up to its contract, whereupon the local company was asked for help, and was able to afford it in a very substantial manner. In every particular the plant is American, a fact that does not lose in significance because Jamaica is a British colony. Whatever may be the political ties of the island, there can be no question that her commercial relations with America become more and more friendly.

ELECTROMAGNETIC THEORY.—XI.

BY OLIVER HEAVISIDE.

(Continued from page 96.)

§ 66. One of these extensions refers to the meaning to be attached to the term current, electric or magnetic respectively. As we have seen, electric current, which was originally conduction current only, had a second part, the displacement current, added to it by Maxwell, to produce a circuital flux; and further, when there is electrification in motion, we must, working to the same end, add a third term, the convection current, to preserve circuitality.

A fourth term may now be added to make up the "true" current, when the medium supporting the fluxes is in motion. Thus, let us separate the motional electric and magnetic forces from all other intrinsic forces that go with them in the two circuital laws (voltaic, thermo-electric, &c., § 39); denoting the former by $\mathbf{e}$ and $\mathbf{h}$, and the latter by $\mathbf{e}_0$ and $\mathbf{h}_0$. The two equations of circuitation [(12), (13) § 38, and (6), (7) § 52)] now read

$$\text{curl}\,(\mathbf{H}-\mathbf{h}_0-\mathbf{h})=\mathbf{J}=\mathbf{C}+\dot{\mathbf{D}}+\mathbf{u}\rho, \quad . \quad . \quad . \quad (1)$$

$$-\text{curl}\,(\mathbf{E}-\mathbf{e}_0-\mathbf{e})=\mathbf{G}=\mathbf{K}+\dot{\mathbf{B}}+\mathbf{w}\sigma. \quad . \quad . \quad (2)$$

Now transfer the $\mathbf{e}$ and $\mathbf{h}$ terms to the right side, producing

$$\text{curl}\,(\mathbf{H}-\mathbf{h}_0)=\mathbf{J}_0=\mathbf{C}+\dot{\mathbf{D}}+\mathbf{u}\rho+\mathbf{j}, \quad . \quad . \quad (3)$$

$$-\text{curl}\,(\mathbf{E}-\mathbf{e}_0)=\mathbf{G}_0=\mathbf{K}+\dot{\mathbf{B}}+\mathbf{w}\sigma+\mathbf{g}, \quad . \quad . \quad (4)$$

where $\mathbf{j}$ and $\mathbf{g}$ are the auxiliaries before used, given by

$$\mathbf{j}=\text{curl}\,\mathbf{h}, \qquad \mathbf{g}=-\text{curl}\,\mathbf{e},$$

It is the new vectors $\mathbf{J}_0$ and $\mathbf{G}_0$ which should be regarded as the true currents when the medium moves.

As the auxiliaries $\mathbf{j}$ and $\mathbf{g}$ are themselves circuital vectors, there may not at first sight appear to be any reason for further complicating the meaning of true current when separated into component parts, for the current $\mathbf{J}$ is circuital, and so is $\mathbf{J}_0$, which is of course the same as $\mathbf{J}$ when the medium is stationary. The extension would appear to be an unnecessary one, of a merely formal character.

On the other hand, it is to be observed that from the Maxwellian method of regarding the current as a function of the magnetic force, the extended meaning of true current is not a further complication, but is a simplification. For whereas in the equation (1) we deduct from the force $\mathbf{E}$ of the flux not only the intrinsic force $\mathbf{e}_0$ but also the motional force $\mathbf{e}$ to obtain the effective force whose curl measures the current; on the other hand, in (3) we deduct only the intrinsic force. Away, therefore, from the sources of energy which are independent of the motion of the medium, the force whose curl is taken in (3) is the force of the flux, which specifies the electric state of the medium, whether it be stationary or moving.

To show the effect of the change, consider the example of § 56, in which the medium moves past the charge, and there is continuously changing displacement outside a certain sphere. If we consider $\mathbf{J}$ the true current, we should say there is electric current, although there is no magnetic force. But according to the other way there is no true current, and the absence of magnetic force implies the absence of true electric current.

But still this question remains, so far, somewhat of a conventional one. Is there any test to be applied which shall effectually discriminate between $\mathbf{J}$ and $\mathbf{J}_0$ as the true current? There would appear to be one and only one; viz., that $\mathbf{e}_0$ being an intrinsic force, its activity, whatever it be, say $\mathbf{e}_0\mathbf{x}$, expresses the rate of communication of energy to the electromagnetic system from a source not included therein, and not connected with the motional force $\mathbf{e}$. When the medium is stationary $\mathbf{x}$ is $\mathbf{J}$, and the question is, is $\mathbf{x}$ to be $\mathbf{J}$ or $\mathbf{J}_0$ (or anything else) when the medium moves?

Now this question can only be answered by making it a part of a much larger and more important one; that is to say by a comprehensive examination of all the fluxes of energy concerned in the equations (1), (2), or (3), (4), and their mutual harmonisation. This being done, the result is that $\mathbf{e}_0\mathbf{J}_0$ is the activity of $\mathbf{e}_0$, so that it is $\mathbf{J}_0$ that is the measure of the true current, with the simpler relation to the force of the flux; and it is naturally suggested that in case of further possible extensions, we should follow in the same track, and consider the true current to be always the curl of $(\mathbf{H}-\mathbf{h}_0)$, independently of the make up of its component parts.

This is not the place for a full investigation of this complex question, but the main steps can be given; not for the exhibition of the mathematical working, which may either be taken for granted, or filled in by those who can do it, but especially with a view to the understanding in a broad manner of the course of the argument. Up to the present I have used the notation of vectors for the concise and plain presentation of principles and results, but not for working purposes. This course will be continued now. How to work vectors may form the subject of a future chapter. It is not so hard when you know how to do it.

§ 67. The principle of the conservation or persistence of energy is certainly as old as Newton, when viewed from the standpoint of theoretical dynamics. But only (roughly speaking) about the middle of the present century did it become recognised by scientific men as a universal truth, extending to all the phenomena of Nature. This arose from the experimental demonstrations given (principally those of Joule), that in various cases in which energy disappeared from one form, it was not lost, but made its appearance in other forms, and to the same amount.

The principle is now-a-days a sure article of scientific faith. Its ultimate basis is probably the conviction (a thoroughly reasonable one) that the laws of motion hold good in the invisible world as well as in the visible, confirmed by the repeated experimental verification. But the principle is now believed in quite generally by the ordinary unscientific man, for example, who could not tell you correctly what the principle meant, or energy either, to save his life, although he might tell you that he could not conceive the possibility of energy being destroyed. He goes by faith, having taken it in when young.

So it will be with the modern view of the ether as the medium through which energy is being sent when a wire supports a current. Only train up the young to believe this, and they will afterwards look upon the notion of its going through the conductor as perfectly absurd, and will wonder how anyone ever could have believed it. But before this inevitable state of things comes to pass, an intermediate period must be passed through, in which scientific men themselves are learning to believe the modern view thoroughly from the evidence of ts truth, and to teach it to others. This period is certainly not yet come to its end; for almost weekly we may read about "the velocity of electricity in wires," such language emanating from scientific men who are engaged in repeating and extending Hertz's experiments.

The principle of the continuity of energy is a special form of that of its conservation. In the ordinary understanding of the conservation principle it is the integral amount of energy that is conserved, and nothing is said about its distribution or its motion. This involves continuity of existence in time, but not necessarily in space also.

But if we can localise energy definitely in space, then we are bound to ask how energy gets from place to place. If it possessed continuity in time only, it might go out of existence at one place and come into existence simultaneously at another. This is sufficient for its conservation. This view, however, does not recommend itself. The alternative is to assert continuity of existence in space also, and to enunciate the principle thus:—

When energy goes from place to place, it traverses the intermediate space.

This is so intelligible and practical a form of the principle, that we should do our utmost to carry it out.

The idea that energy has position, therefore, naturally involves the idea of a flux of energy. Let $\mathbf{A}$ be the vector flux of energy, or the amount transferred per unit of time per unit of area normal to the direction of its transfer; and let $\mathbf{T}$ be the density of the energy. We may then write

$$\text{conv}\,\mathbf{A}=\dot{\mathbf{T}}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

or

$$\text{div}\,\mathbf{A}=-\dot{\mathbf{T}}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Digitized by Google

That is, the convergence of the flux of energy is accounted for by increased energy in the unit volume where it converges; or, the divergence of the flux of energy, or the rate at which it leaves the unit volume, is accompanied by simultaneous and corresponding decrease in the density of the energy.

§ 68. Now, there are numerous cases in which the flux of energy is perfectly plain, and only needs to be pointed out to be recognised. The simplest of all is the mere convection of energy by motion of the matter with which it is associated. A body in translational motion, for instance, carries its energy with it; not merely the kinetic energy of its translational motion, but also its rotational energy if it rotates, and likewise the energy of any internal vibratory or rotatory motions it may possess, and other energy not known to be kinetic, and therefore included under "potential energy," which we may have good reason to localise in the body. Even if part of the energy be outside the body, yet, if it be associated with the body, it will travel with it, on the whole, and so (at least sometimes) may be considered to be rigidly attached to it. This case may be regarded as the convection of energy, if we do not go too closely into detail.

When energy is thus conveyed, the energy flux is $\mathbf{q}T$, where $\mathbf{q}$ is the velocity and T the density of the energy conveyed (of any kind). If, then, *all* energy were conveyed, equation (5) would become

$$\text{conv}\, \mathbf{q}T = \dot{T}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

Now this equation, if we regard T as the density of matter, is the well known equation of continuity of matter used in hydrodynamics and elsewhere.

This brings us to Prof. Lodge's theory of the identity of energy. (*Phil. Mag.*, 1885.) Has energy personal identity, like matter? I cannot see it, for one; and think it is pushing the principle of continuity of energy, which Prof. Lodge was writing about, too far. It is difficult to endow energy with objectivity, or thinginess, or personal identity, like matter. The relativity of motion seems to be entirely against the idea. Nor are we able to write the equation (7) in all cases. Energy may be transferred in other ways than by convection of associated matter. If we atomise the energy we can then imagine the $\mathbf{q}$ above to be the velocity of the energy, not of the matter. But as the science of dynamics is at present understood, we cannot make use of this idea profitably, I think.

The chief reason why the founders of the modern science of energy did not explicitly make use of the idea of the continuity of energy was probably the very obscure nature of gravitational energy. Where was it before it became localised as the kinetic energy of a mass? It is of no use to call it potential energy if that is to explain anything, which it does not. It would seem that the energy must have been in the ether, somewhere, and was transferred into the body, somehow. This makes the ether the great store-house of all gravitational energy. But we are entirely ignorant of its distribution in the ether, and of its mode of transference.

Observe here that ether must be regarded as a form of matter, because it is the recipient of energy, and that is the characteristic of ordinary matter. There is an unceasing enormous flux of energy through the ether from the Sun, for instance, and we know that it takes several minutes to come; it comes through the ether, without bringing the ether with it; it is not a convection of energy, therefore. Of course, to avoid confusion, it is well to distinguish ether from ordinary matter by its separate name; but it is important to note that it *has* some of the characteristics of ordinary matter. It need not be gravitating matter; it is, perhaps, more likely to be the medium of gravitational action than to gravitate itself.

In default of ability to represent the flux of gravitational energy its entry into a body must be otherwise represented than by the convergence of a flux. Turn (7) into

$$\mathbf{f}\mathbf{q} + \text{conv}\, \mathbf{A} = \dot{T}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

Here $\mathbf{f}\mathbf{q}$ is the activity of the force $\mathbf{f}$, and indicates energy communicated to the unit volume in an unstated manner, generated within the unit volume, so to speak. The force $\mathbf{f}$ is thus an impressed force. By this device we can allow for unknown fluxes of energy. We should also explicitly represent the convective flux. Thus,

$$\mathbf{f}\mathbf{q} + \text{conv}\,(\mathbf{q}T + \mathbf{A}) = \dot{T}, \quad . \quad . \quad . \quad . \quad . \quad (9)$$

where $\mathbf{A}$ is the flux of energy other than convective, not associated with $\mathbf{f}$.

When a stress works, for example, we shall have a flux of energy, $\mathbf{A}$, which can hardly be considered to be convective, in the sense explained, a flux of energy through matter or ether, as in wave propagation through an elastic solid, or radiation through the ether. We can, however, sometimes reduce it to the form $\mathbf{q}T_1$, and then it would *appear* to be convection of energy.

This occurs in a moving frictionless fluid, for example, when the stress is an isotropic pressure p. The flux of energy other than convective is $p\mathbf{q}$. But when we pass to a less ideal case, as an elastic solid, in which the stress is of a more general character, the energy flux expressive of the activity of the stress takes the form

$$\mathbf{A} = -\mathbf{P}_q q, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

where $\mathbf{P}_q$ is the vector expressing the pull per unit area on the plane perpendicular to the velocity $\mathbf{q}$. In this equation q is the tensor of $\mathbf{q}$.

(To be continued.)

NOTES ON PERMANENT MAGNETS.

BY SILVANUS P. THOMPSON, F.R.S.

§ 1. **Laminated Magnets.**—Knight appears to have been the first to employ compound magnets made of bundles of steel plates separately magnetised. Since then many other experimenters have adopted this construction, notably, Geuns, Coulomb, and Scoresby. The advantage of this construction is that, in the methods adopted for hardening steel by sudden quenching, the hardening does not really penetrate far below the surface, and, consequently, the interior softer part of the bar adds nothing to the permanent magnetism, and may even weaken it so far as its external manifestation is concerned. Coulomb employed magnets made up of three laminæ, the central one projecting a little beyond the others, their ends being embedded in a soft-iron pole-piece. Scoresby,* who made many researches on compound magnets, showed that it was advantageous to separate the laminæ to a short distance apart. Some of his magnets, prepared from busk steel, are preserved in the Museum at Whitby. He showed that such compound magnets may be made much more powerful than any single bar, of weight equal to the combination, can be made; but that the absolute gain of power in the combined mass, due to each additional lamina, diminishes progressively. For example, in a set of 30 plates the last 26 did not add to the first four more magnetic power than the first six had possessed alone. This is due to the tendency to mutual demagnetisation; for in a powerful set the weaker plates not only add nothing but have their polarity actually reversed by the more powerful ones. This state of things is partially remedied by preventing the actual contact of the plates, by interposing sheets of paper or brass. Scoresby found that for compound horse-shoe magnets the best temper was not glass-hard. He found it better to temper the hard steel plates by boiling them in linseed oil at 505°F (=263°C). In this way he raised the lifting power of a 5-plate Stubbs' steel horse-shoe weighing 2·91lb. from 13-14lb. to 25-26lb. And another 15-plate magnet weighing 8lb., which when glass-hard would only carry 26lb., when thus tempered carried 45-50lb. Jamin,† who has gone over the same ground, has added little to the very complete investigations of Scoresby. Some makers of compound magnets arrange the tiers of plates in the form of steps at the extremities, the central plates being made longer than those on either side. There is no great gain in this arrangement, which is supposed to prevent the central plates from being reversed in

* Scoresby's "Magnetical Investigations," Vol. I., pp. 98—329.

† *Comptes Rendus*, LXXVI., 1873, and in innumerable Papers in the same journal since.

Digitized by Google

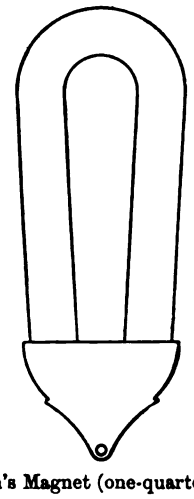
polarity by those outside. It probably has the advantage of concentrating the magnetic lines, and so adding to the lifting power. Van der Willigen considered one millimetre a sufficient amount of projection for the central plate.

§ 2. **Traction or Lifting Power of Magnets.**—Bernoulli's law that the tractive power of similar magnets was in proportion to the $1\frac{2}{3}$th root of their weight, or, in other words, to the square of the cube root of their weight, was explained in my Cantor Lectures on the Electro-magnet, and shown to mean merely that for equal magnetic saturation the tractive power was simply proportional to the polar area. If P stands for the greatest load which the magnet will carry, and W for its own weight, then Bernoulli's rule is

$$P = a \sqrt[3]{W};$$

where a is a constant depending on the units chosen, on the quality of steel, and on its degree of magnetisation. If P and W are expressed in kilogrammes, then, according to the data of the best makers, a for horse-shoe magnets will be between 18 and 24, or, say, on the average, 20. This means that if we consider a magnet weighing 1 kilogramme, it will carry a load of 20 kilogrammes, or 20 times its own weight. On this reckoning a magnet weighing 10 kilogrammes should carry 92·8 kilogrammes, or $9\frac{1}{4}$ times its own weight; whilst a magnet weighing 0·1 kilogramme should carry 4·31 kilogrammes, or 43 times its own weight. If P and W are given in British pounds the value of the coefficient for the best sort of horse-shoe magnets (corresponding with $a = 20$ for kilogramme units), will be 25·1, or, approximately, 25. That is to say, a really good steel horse-shoe magnet, weighing 1lb., should carry a load of 25lb. For example, one of Van Wetteren's magnets examined by Van der Willigen (magnet "B") weighed 1·074lb., and carried, as the mean of seven observations, a load of 26·004lb.

§ 3. **The Haarlem Magnets.**—The Haarlem magnets have been so justly celebrated for their admirable qualities



Van Wetteren's Magnet (one-quarter actual size).

that some notice of them seems to be called for. Logeman, who was continually advised by M. Elias, was the first to establish a name for the magnets made in Haarlem. By him, Van Wetteren, a most accomplished master smith, had been employed. Later, when Funckler succeeded to Logeman's business, both Van Wetteren and Funckler continued to produce magnets on Elias' plan, until, in 1874, M. Van der Willigen superseded that method of magnetisation by a special method of magnetising upon the poles of a Ruhmkorff's electro-magnet, and applied it to the magnets forged by Van Wetteren. Of the special kind of steel employed, and of the mode of hardening and tempering adopted, nothing precise is stated in the otherwise valuable memoir of Van der Willigen* on the subject. In this memoir a detailed account is given of about 50 magnets and of the loads which they carried after being magnetised in various ways and at various times. Most of these magnets were of the form shown in the figure. The contact surface of the keeper is slightly rounded. The Figure is exactly one-quarter the natural size of the magnet "A" in the following list:—

Mark on magnet.	Weight of magnet, in kilos.	Average load carried, in kilos.	Value of coefficient a.
A	0·495	13·30	21·25
B	0·487	11·78	19·03
E	0·889	19·02	20·57
3057	1·013	21·71	21·52
3053	1·521	27·90	21·17
3054	1·918	32·53	21·07
C	2·169	35·47	21·10

The magnet "A" was 0·66 centims. thick, its keeper 0·3 centims. thick, the polar ends were 2·57 centims. apart, and each of them was 2·68 centims. wide. The extreme height from the outer side of the bend to the middle point between the poles was 17 centims. The area of the polar face was 1·769 sq. centims. The greatest width between the limbs below the bend was 3·65 centims. The magnets "A," "B," "E," and "C" were from one bar of steel. The magnet "3,053" was one shown in the Exhibition of Scientific Apparatus at South Kensington, in 1876, whilst "3,054" was sent to the Centennial Exhibition, at Philadelphia, in the same year. When returned from the States in May, 1877, it was re-magnetised, and carried 31·44 kilogrammes.

So far as the author is aware, no British manufacturers have equalled the Haarlem makers; certainly none has surpassed them.

Scoresby* mentions a nine-plate compound horse-shoe in his possession, weighing 22lb., which would carry from 66 to 88lb. By Bernoulli's formula, a 1lb. magnet, proportionately magnetised, would carry from 8·4 to 11·3lb.—less than half the load which a 1lb. Haarlem magnet will carry. Scoresby also mentions a seven-plate steel horse-shoe made by Dr. Schmidt, the property of the Royal Institution, which, though weighing 16lb., would only carry 28lb. Had this been a Haarlem magnet it would have carried at least 150lb.

Van der Willigen gave another formula for the tractive force of the Haarlem magnets, namely:—

$$P = B \cdot K \sqrt{S} \sqrt[4]{\frac{L}{S}} \frac{L}{l};$$

where P is the tractive force in kilogrammes, S the area of one polar surface (in sq. centims.), K the perimeter of one polar extremity, l the actual mean length of the horse-shoe, L the "reduced" length (*i.e.*, the length between the points of maximum free magnetism observed on the flanks of the magnet, when keeper is in place), all the last being given in centimetres. B is a coefficient which varies between 0·7 and 1·2, and has a mean value of 0·891.

The tractive power of bar magnets is, of course, much less than that of horse-shoes of equal weight, since the keeper is never so highly magnetised when applied to one pole. Van der Willigen states that for Van Wetteren's bar magnets the load carried by one pole is just a quarter of the load which a horse-shoe (of weight equal to that of the bar) would carry. This means that Bernoulli's coefficient a (for kilogramme units) must be taken at about 5 for Haarlem bar magnets. The corresponding number for pound units will be $6\frac{1}{4}$. Has any British maker yet produced a steel bar magnet weighing 1lb. which will carry $6\frac{1}{4}$lb. on one pole?

ELECTRIC LIGHTING IN THE CITY.

The 26 arc lamps which have been erected in Queen Victoria-street, and which constitute as yet the only visible result of the work which is being carried out in the City, were run on Thursday last, for public demonstration, and for the purpose of affording the Commissioners of Sewers an opportunity of inspecting them, the gas lamps being extinguished.

The opinion of the daily Press, which is perhaps a thoroughly representative one, was very favourable. The light is described

* Sur le Magnétisme des Aimants Artificiels. "Arch. du Musée Teyler" (Haarlem), Vol. IV., 1878.

* *Op. cit.*, p. 244.

Digitized by Google

as "brilliant, yet soft." "The old objection with regard to the depth of shadows thrown by the lights has been largely modified. The lights also burned quite steadily, with hardly an exception, and there was little or no variation in their intensity." One paper compares the effect to moonlight, and says that, "although every object was plainly visible, there was perfect rest for the eyes." All are agreed that this first instalment is a success, and that the gas lights in the neighbouring streets were mere sparks of dim red fire. After all, it is the opinion of the general public that is to be consulted, since theirs are the requirements to be satisfied. The value of the lighting cannot be properly estimated until the winter, when the streets are crowded after dark; and before the long evenings set in many more streets will probably be lighted. On entering the top of Queen Victoria-street, after walking along Cheapside, where clusters of four gas-burners are provided in each lamp, the general effect was very good, but not particularly remarkable. Having walked the length of the street, and glancing up New Bridge-street, which is lighted simply by gas, the contrast seemed very much more marked than on entering the well illuminated thoroughfare from Cheapside. It is this contrast, rather than the usefulness of the increased illumination, which will cause arc lighting to spread in our streets. The public are fairly satisfied with good gas lighting, but they will complain about it as soon as they leave a district lighted by arcs.

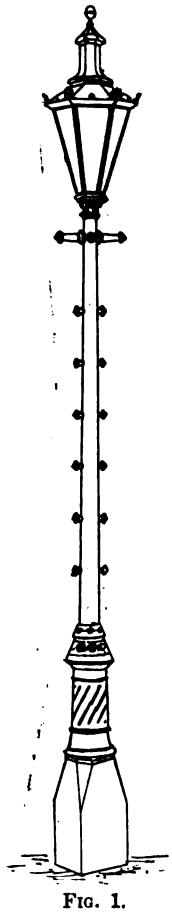


Fig. 1.

The arc lamps are placed on columns 19ft. high (Fig. 1), and are enclosed in lanterns of agreeable proportions. The columns are about 120ft. apart, and are placed alternately on either side of the street. The lanterns are octagonal, and are provided with panes of glass, of which three kinds are being tried. Between the Mansion House and Cannon-street a pane moulded with a small obtuse pyramid is used. The angle of the prisms thus formed is sufficient to deflect the light some 8 or 10 degrees, giving a dispersion of 18 or 20 degrees. But on the occasion of our visits the arcs have been so low in the lanterns, and therefore so near the glass, that the part of the pane subtending this angle with the arc was scarcely as large as the palm of one's hand. If the arc had been twice as far from the glass the patch of bright light would have been twice as wide, and its area, and, therefore, the brilliancy or dazzling, would have been reduced to one-fourth. From Cannon-street to Lambeth-hill a figured pane, with a fancy pattern moulded on it, is used. This disperses the light considerably more than the pyramid, the dazzling is less, and the shadows are softened. The rest of the lanterns, as far as St. Paul's station, have opal glass of a thickness sufficient to prevent the position of the arc being seen. The shadows are, of course, soft, and there is a minimum of dazzling at the expense of a considerable absorption, which is impossible to estimate by the eye, but which is probably over 40 per cent. The theoretical limit of diffusion with moulded panes of clear glass is internal reflection; but a dispersion of 40 or 50 degrees can be given. The best way to select a pattern is, no doubt, to try it on a few lamps, as is being done in Queen Victoria-street, judging the diffusion by the size of the apparent patch of light for a given distance between the arc and the glass, and measuring the absorption with a photometer. The practical difficulty which arises with all kinds of prismatic glass is that of cleaning it. This is found to be a most serious obstacle to the outdoor use of glass specially designed for dealing with the light according to optical laws. Not only is an increased expense involved, but the settling of dust and dirt on and between the prisms obstructs the light to such an extent that the advantages which it may possess when clean are soon lost. Hitherto we have been speaking merely of diffusion of the light for the purpose of softening shadows and diminishing dazzling. No attempt is made to equalise the distribution of the light, except by placing the lamps at a considerable height, and this is probably better, under the circumstances, than any use of prisms or reflectors. We are inclined to think that the effect would be much better if the mean position of the arcs were 9 or 10in. higher in the lantern. This, with a Brush lamp, would entail an alteration in the hood, and might make the lantern look a little top-heavy. Rays above the horizontal are very little use; but at present the top of the glass is at an elevation of some 45 degrees above the arc.

Columns of various heights have been tried. We noticed the other day that the leads were carried outside from one of the lanterns, and it was not until we examined it closely that we found that the shaft, which was painted green to match the pedestal, was only a scaffold pole, used for the purpose of experimenting as to the best height. The difficulty of using a long ladder (since the idea of lowering the lamps for trimming is out of the question) has been got over by providing sliding steps, which can be pulled out on alternate sides, the lowest being about 8ft. from the ground. A short ladder only need thus be

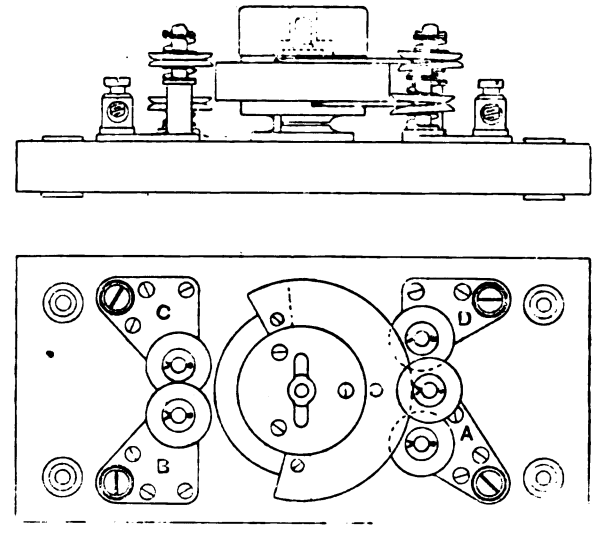

Fig. 2.—Short-circuiting Switch in the base of the Lamp-posts.

carried. In each pedestal is a switch, by which any lamp can be cut out without breaking the circuit. Fig. 2 shows a side and a front elevation of the switch. On a wooden cylinder are mounted two sectors of sheet brass, the lower one being semicircular, and the upper projecting a little beyond. These discs pass between bevelled washers, which are pressed together by springs. The current passes from A to B, and returns, after going through the lamp, from

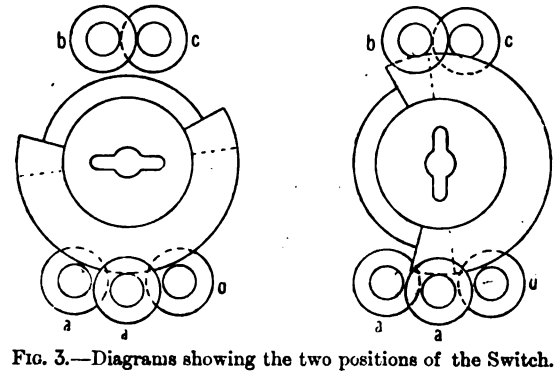

Fig. 3.—Diagrams showing the two positions of the Switch.

C to D. In Fig. 3 the two positions are shown. The two sets of washers, *a a*, are connected to the same pole, one being on the level of the upper sector, and one on the level of the lower. In the right-hand diagram it will be seen that the upper washer, *a*, is connected to *b* by the upper sector, while *c* is connected to *d* by the lower one. On turning the switch, the lower sector makes contact with the lower washers, *a*, just before the upper sector breaks circuit at *b*. The lower washers, *a*, are, therefore, short-circuited with *d* by the lower sector, the lamp being cut out.

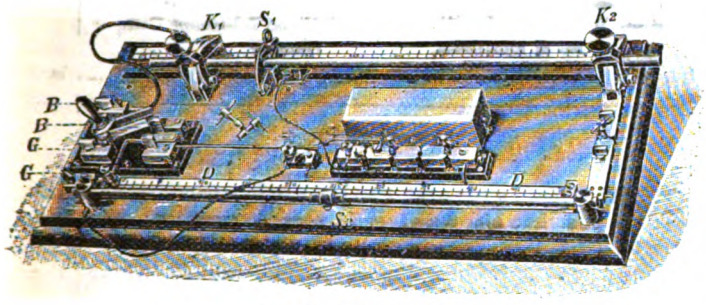
The streets of the districts allotted to the Brush Company will be lighted in all by 282 arc lamps of 2,000 nom. c.p., and by 600 incandescent lamps of varying candle-power in the smaller thoroughfares. The mains from the generating station at Bankside are at present laid across Southwark Bridge, but for the purposes of lighting the western division the mains will be laid from the generating station across Blackfriars Bridge. The station of the Brush Company has a capacity of 880 2,000 c.p. arc lamps and 240,000 incandescent lamps of 8 c.p.

THE FRANKFORT EXHIBITION.—IV.

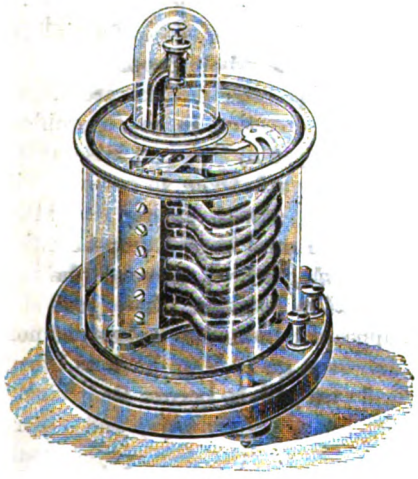
(FROM OUR SPECIAL CORRESPONDENT).

The Hartmann and Braun collection of instruments is especially worthy of notice, and contains, amongst other things, a low resistance bridge, a new form of Deprez's galvanometer, and Braun's electric pyrometer. The bridge for measuring low resistances is a modification of the Wheatstone bridge, in which contact resistances by means of double readings are eliminated.



Low Resistance Bridge.

Two clamps, K_1, K_2, are provided, which will hold rods or wires of any section, and will grip lengths up to 21in., the length of the conducting material measured being read off on a scale. Between G and G is the mirror galvanometer, and several constant cells between B and B. Two bridge plugs, such as 10 and 100, are withdrawn, and the movable contact S_1 is brought near to K_1, and afterwards near to K_2, the balance of the galvanometer being restored in each case by the adjustment of the

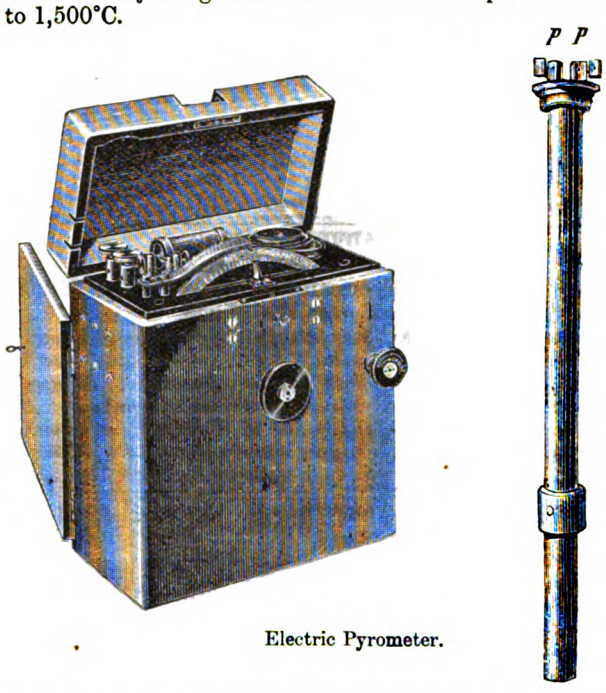


Deprez Galvanometer.

contact S_2. The resistance between the two positions of S_1 is thus measured by a comparison of the fall of potential with the fall of potential over the calibrated wire D. Errors due to the contact resistances are thus avoided. The instrument is provided with a double switch to complete the battery and galvanometer circuits in succession.

The new form of Deprez's galvanometer differs from the original in some notable respects. It has six strong horseshoe magnets, placed horizontally one above the other, and having common pole pieces. By this means a powerful, constant, uniform field is produced, and great sensitiveness attained. There is a metal torsion suspension at the top, and a silk fibre at the bottom of the coil to keep it in position, the former constituting one connection of the coil, the circuit being completed by a delicate spiral at the bottom. The sensitiveness thus lost by the use of the spiral is just half that of the ordinary Deprez instrument with two metal suspensions. The galvanometer has effective air damping, and is little affected by external magnetic fields. This firm is well known in Germany, particularly from its ammeters and voltmeters, their clear and large reading scales giving these instruments additional value.

Braun's pyrometer has for principle the variation of the resistance of a wire of platinum with the temperature. The instrument is neatly carried out and seems capable of considerable sensibility even at the high readings; it consists of a fireproof tube into which the platinum wire, non-inductively wound, is mounted. The ends are connected with the clamps P and P. A solid oak case is arranged to hold dry cells, which are introduced through a door at the back. They are connected with telephone or mirror galvanometer, and the wire on the revolving wheel, together with the platinum wire, the resistance of which is wanted, are arranged as a Wheatstone bridge; the scale on the adjusting wheel reads off the temperature direct up to 1,500°C.



Electric Pyrometer.

As, of course, the distance of the pyrometer from the bridge is immaterial so long as conductors of very small resistance are used, the instrument may be called a telepyrometer, and temperatures of furnaces, &c., read off from a distance. The chief merit of the arrangement is its portability.

Faraday Centenary Lectures.—Prof. Dewar delivered the second of the Faraday centenary lectures at the Royal Institution, on Friday evening, the Duke of Northumberland occupying the chair. The lecture was devoted mainly to the achievements of Faraday in chemical science, as that of Lord Rayleigh's last week was to his physical researches, and was illustrated and explained by experiments, which were performed with admirable success. The principal feature of the lecture was the production of liquid oxygen, which was exhibited boiling at a temperature of about – 200 degrees C., or nearly 400 degrees below the freezing point of Fahrenheit. This result was achieved by the combination of exceedingly low temperatures, produced, in this instance, by ethylene and enormous pressure, and was one which, so far back as 1845, Faraday hoped to attain. A vote of thanks was accorded to Prof. Dewar, on the motion of the Lord Chancellor, seconded by Sir Lyon Playfair, who referred to the fact that Prof. Dewar was his pupil in chemistry.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements should be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL PREPAID ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1891 Edition, published on the 23rd February, 1891, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with well-written Biographical Notices of leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1891 should be ordered at once. Price 5s., post free 5s. 9d. Abroad postage extra. Prospectuses free.

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. Vol. I. Price 7s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Vol. I. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

Several Further Volumes in Active Preparation.

NOW READY, IN TWO VOLUMES.

"THE ELECTRICIAN" PRIMERS.

Fully Illustrated.

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

STREET LIGHTING.

Street paving, street lighting, and street decoration are among the works which are carried out for the convenience and enjoyment of the whole community, at an expense which is largely, if not almost entirely, borne by the wealthier classes. The refinements of civilisation, prompted by motives of self-interest, are introduced in the first instance for their own gratification by those who appreciate them, but, as the luxuries of one age become the necessities of the next, these refinements, in a well developed state of society, overflow their source, and extend to the whole people. The street decoration provided by ancient and modern architecture, and culminating in another direction in the magnificent flowers in our parks, may be enjoyed by the most miserable vagrant, who contributes nothing towards them, in common with the largest ratepayer of the day. Street paving has attained a high degree of excellence in most large European cities, and to this electric lighting is being added, although the reverse order of things is to be found in America, where good street paving, if not unknown, appears to be neither understood nor appreciated. We need not, however, go to New York to learn how to light our streets, nor do we wish to borrow their elevated railroads, phonographs, trolley-wire tramways, and other products of transatlantic civilisation. If the ratepayers really want electric light in their streets, it can be provided with the greatest ease.

The appliances and means for lighting seem to have a picturesqueness and beauty which are inverse to their efficiency and power. The lamps of Pompeii probably yielded as small a candle-power as any lamp could give, but have never been surpassed for grace. The beautiful iron lanterns of north Italy were intended to light the entrances to the palaces rather than afford illumination for the passers by, and the

Digitized by Google

old torch holders remind us that those who had to be abroad after nightfall generally used a torch, the oldest form of light, as is indicated by the etymology of the word lamp. A few torch-holders, and many torch extinguishers, are to be found to-day on the ironwork of gates and railings in London, and here and there a ring which once held an oil lamp. Such lighting sufficed for the requirements of the time; indeed, we are informed by an eye-witness that Grosvenor-square and St. James's-square were "very handsomely lighted" by oil lamps, which were daily removed, trimmed, and replaced by porters, who trundled them through the streets in barrels. There are a good many small towns to-day which, either having no gas, or having quarrelled with the price charged for street lighting, still content themselves with the smoky twinkle of the oil flame. A general illumination of the streets in the old days was only to be seen on rare occasions of public rejoicing, when everybody set a light in his window, and testified to his festivity by a homely display, but one which showed more sympathy and feeling for the festival than the flaming devices of gas-pipe and gaudy glass-work which are hired at so much a night for our modern jubilees.

When, after sundry experiments at Birmingham and Salford, gas lighting was introduced in London in 1813, it was first seen on Westminster bridge, and immediately after made rapid progress. For no purpose was it better adapted than for street lighting, and, unlike electrical illumination, it was extensively employed for public lamps from its earliest days. The change was not revolutionary, for there was no prodigality of lamps, and the same old square lanterns have been used in many London streets with but little alteration. To-day such old-fashioned contrivances suffice for the lighting of that part of Piccadilly which runs along the park, one of the most characteristic streets of London, and at this time of the year one of the most attractive. The lamps are a little closer together than in less important thoroughfares, but the illumination *as* illumination, for the purpose of reading a newspaper or finding a fallen sixpence, is of the feeblest kind. The double row of lights just serves to trace the route ahead, as a channel is marked by buoys. At Hyde Park Corner we have, perhaps, the best bit of street lighting in London, and it seems to be effected at a most disproportionate cost. The only idea is to bunch a number of gas burners together in a glazed furnace, for the regenerative and other novel burners in which some originality was attempted have long ago disappeared. Market-street, Manchester, is well lit, but the lighting, like that of many thoroughfares, is largely assisted by the shops. The opinion has been expressed by many people who have visited the United States that the street lighting, which is considered in that country to be so necessary, is not altogether ornamental or practically useful. Our American visitors are always astonished at the gloom of our streets, and we do not hesitate for a moment to say that an increased light is necessary; but it is necessary that the use of arc lights in the City should be extended with caution.

Ten years and two months have elapsed since, on April 1, 1881, the streets from London-bridge to Blackfriars, St. Paul's Churchyard, Cheapside, including both open spaces, and narrow thoroughfares were lit by what were then called the "Siemens system" and the "Brush system." High lattice posts supported clear glass globes at such a height above the pavement that it was fondly hoped that the atmosphere, about the transparency of which we so often complain, would tone down the shadows and subdue the glare. Unfortunately, the very contrary was found, and when, after many troubles, the premature attempt was abandoned, little or no effort was made by the contractors to renew the work, for it was not remunerative, and the public, so far from finding that they could not do without it, have almost forgotten that they ever enjoyed it, and it is only remembered as a rather unpleasant combination of flickering glare and exaggerated shadows. The causes of the sudden extinctions, both total and local, were recorded in our columns, and were due to the breaking of driving belts or of governors, the slipping of brushes from their holders, and of carbons from their rods; and one or two cases of faulty insulation added to the many troubles which beset the work. Where the light was valuable and was duly appreciated, it has been used continuously during these past ten years—at the British Museum, and at Charing-cross and other stations. The inscrutable workings of Fate, operating in conjunction with the hardly less intelligible doings of the Commissioners of Sewers, have so ordered matters that the revival of street-lighting by electricity should fall at the summer solstice, and it follows that he who would criticise the result must make a special expedition to Queen Victoria-street, unless he be among those few stragglers who are detained there after night-fall. Such a special journey will be undertaken by but few enthusiasts, or by those, who, like ourselves, have treated it as a matter of duty. The result, which is dealt with in detail in another column, appears not only to be satisfactory but to have an air of permanence about it, which says that it has come to stay.

No part of London is so well paved, kept in such first-rate repair, so carefully cleaned in the small hours of the night, and generally looked after, as the City. The vestries, with their petty squabbles, and constant endeavours to make the rates go as far as possible, and to throw their burdens on to other shoulders, look after the streets with varying success. None of them have attempted to light their thoroughfares by electric light as yet, and we doubt whether the ratepayers would sanction the expense. In the meantime, we shall have an excellent opportunity of judging the comfort and usefulness of arc lighting, as shown in the City, and the details as to the height of the posts and the current required; and there can be but little doubt that while nineteen Londoners out of twenty are at present quite satisfied with the lighting of the streets by gas, they will gradually be convinced that an illumination ten times greater than that which they now have, is absolutely indispensable to their convenience and safety.

OBITUARY.

PROFESSOR WILHELM WEBER.

By the death of Professor Wilhelm Edouard Weber, at Göttingen, at the age of 87, we have lost the second of the great trio, Gauss, Weber, and Thomson, who were the architects of the electro-magnetic system of measurement which has been of such incalculable value to the practical electrician.

In the year 1833 Gauss first published his theory of an absolute system of magnetic measurement, and, in 1851, Weber, who had been associated with Gauss in his magnetic measurements, promulgated the first definite system of electric current measurement in terms of absolute units, and henceforth a large proportion of his time and energy were devoted to the development of the system, which was introduced into this country and further developed by the labours of Sir William Thomson and of the British Association Committee on Electrical Standards, appointed at his suggestion in 1861.

Weber and Gauss conjointly established, in 1833, an electric telegraph worked by a voltaic battery, and subsequently by a magneto-electric machine devised by Steinheil, for transmitting signals between the University of Göttingen and their own magnetic observatory. This telegraphic line is of special interest owing to the fact that the receiving instrument was

Digitized by Google

practically identical with what is now known as Sir William Thomson's galvanometer, having been re-invented by him.

The greater part of Weber's work, however, was in close relation with the working out of the electro-magnetic measurement of electric currents, as in the case of his invention of the electro-dynamometer, now so extensively used in the numerous forms which it has assumed to meet the various requirements of the electrical engineer.

Weber's attempt to explain the phenomena of electric current induction by means of an electrostatic repulsion between moving particles carrying electric charges formed a portion of his researches on the electro-magnetic measurement of electric currents, published in 1864 and subsequent years under the title of "Elektrodynamische Maasbestimmungen," in the "Abhandlungen der Math. Phys. Classe der königlichen Sachsischen Gesellschaft der Wissenschaften." Helmholtz showed that Weber's formula led, in certain cases, to impossible results, but Prof. Lindmann, in 1884, showed that certain assumptions as to the nature of the molecules of matter led to Weber's formula, so long as the relative velocity of the particles does not exceed the velocity of light, but when this critical value is exceeded the law no longer holds, and in this form it is not open to Helmholtz's objection.

Weber's well-known theory of magnetic induction was another contribution to electrical science of which it would be difficult to exaggerate the importance, for, although in the light of our present knowledge it is in many respects inadequate, it undoubtedly formed the basis upon which a theory of magnetic induction is being gradually built up.

THE HISTORICAL DEVELOPMENT OF THE INDUCTION COIL AND TRANSFORMER.

BY DR. J. A. FLEMING, M.A.

(Continued from page 213.)

In Silliman's Journal of Science, Page made some very excellent remarks upon the action of "closed circuits" in preventing or reducing the inductive action of the primary current upon the secondary circuit. He states that if a closed circuit, such as a metallic sheath or tube, is interposed between the primary or secondary circuits, it more or less annuls the inductive action of the former on the latter. He hence notes that wrapping, what he calls a "compound magnet," *i.e.*, an induction coil with two separate circuits, in a metallic sheath, greatly reduces the inductive action of the primary on the secondary, although it does not prevent the action of the primary circuit in permanently magnetising the core. The same action he points out proves prejudicial if bobbins, made of metal, or having metal cheeks, are used upon which to wind the circuits of the coil. Hence, bobbins for induction coils should be made entirely of non-conducting material.

We also find that in 1840, J. H. Abbot, of Boston, U.S.A., constructed a large induction coil (see *Silliman's American Journal of Science*, Vol. XL., April, 1841, p. 107), which was capable of charging a Leyden jar, and which gave small secondary sparks. The break was a hand-worked break (*see* Fig. 16*a*). The secondary terminals were described as being luminous in the dark when the coil was in action. This coil was modelled on Page's.

It is evident from the foregoing that, even in the year 1838, C. G. Page had brought the induction coil to a high degree of perfection by his researches made at Salem and at Washington, and in particular had shown that the secondary circuit could exhibit effects of "tension" and produce electrostatic change in conductors having capacity connected with them when induction coils were used in which the secondary currents consisted of great lengths of fine wire. He had obtained sparks in air from the secondary terminals of coils, and shown the conditions under which these "electrostatic" effects could be exalted. We must also credit him with being an independent inventor of the self-acting hammer electro-magnetic contact breaker.

Continuing his researches, Page made many coils between 1838 and 1850, having highly insulated secondary circuits and vibrating automatic contact breakers. He found, as above observed, that he could charge Leyden jars, diverge the gold leaves of electroscopes, and produce many of the effects hitherto only obtained with electrostatic machines by means of these induction coils. With one of his coils he found he could obtain sparks half an inch long in air from the secondary terminals. He noted, also, the effect of rarefying the air round these terminals on the length of discharge. With one coil, which gave a secondary spark of $\frac{1}{16}$th of an inch in air, he obtained a

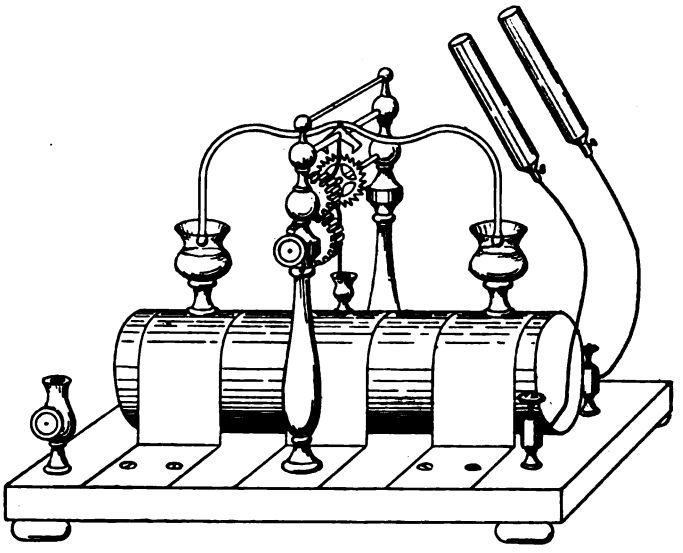

FIG. 16A.—Abbot's Induction Coil (1840).

discharge of about 4½ inches in rarefied air, when the primary circuit was actuated by one single Grove's cell. In 1850 Page constructed a very large coil, of which the primary circuit was a wire or ribbon of copper, one quarter of an inch in diameter. This coil, when worked by 100 Grove's cells, gave sparks from the secondary circuit 8 inches in length.

One striking peculiarity about this large primary coil attracted Dr. Page's notice. When a solid iron core was put into this great helix the primary current took a very sensible fraction of a second to rise to its full value; from $\frac{1}{10}$th to two

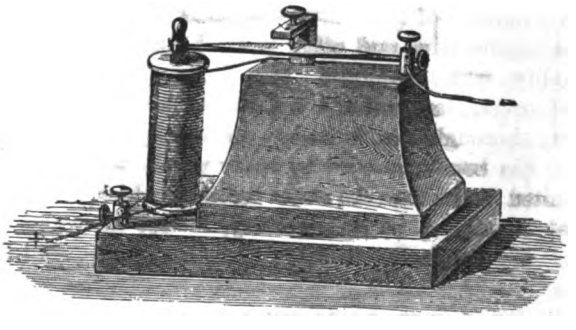

FIG. 17.—Wagner's Automatic Contact Breaker.

seconds, according to the position of the iron core. Page also noted a phenomenon, afterwards recorded by Rhyke in 1855, viz., that when the primary circuit was broken just between the poles of a powerful magnet the break-spark was extinguished with a loud explosion, like that of a pistol when fired.*

§ 10. Wagner and Neef's Automatic Contact Breaker.—Continental writers generally attribute the invention of the automatic vibrating electro-magnetic contact breaker to J. P.

* The greater part of Dr. C. G. Page's valuable work is recorded in his own Papers, published in *Silliman's American Journal of Science* between 1834 and 1850. He published in 1867 a *brochure* entitled the *History of Induction*, which is alluded to by Du Moncel in his work (Vol. II.) *Exposé des Applications de l'Electricité*, but this pamphlet of Page's is not to be found either in the British Museum Library or in the English Patent Office Library.

Digitized by Google

Wagner* and to Neef.† These inventors improved upon Page's mercurial break by constructing the vibrating armature with platinum contacts in the form in which it is now used in every trembling electric bell. The apparatus is too well known to need description. A form of Wagner's hammer, as it is generally called, is shown in Fig. 17, intended as an interrupter to the primary circuit of a coil. Du Moncel, however, states that MacGauley, of Dublin, independently invented the form of hammer contact as now used. From this date onwards it has generally been the custom to interrupt the primary circuit of an induction coil, if small, in the manner introduced by Page in 1838, viz., employing the intermittent magnetism

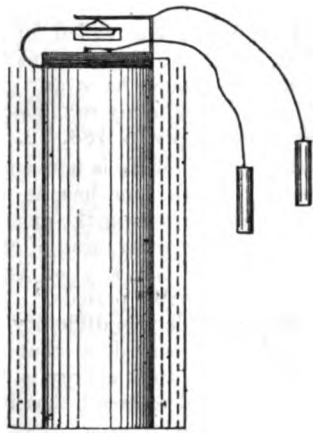

FIG. 18.—Wright's Coil and Contact Breaker.

of the soft iron core of the coil to work the vibrating hammer of the break, using, however, the platinum contacts of MacGauley or Wagner instead of Page's mercurial cup. On the other hand, when the coil is large, the break is usually made as a separate piece of apparatus with independent magnet, and in that case it is often found best to revert to the mercury cup break of Page, and cover, as he did, the surface of the mercury with oil or alcohol to prevent oxidation, as was done subsequently by Ruhmkorff and others. As is usually the case, useful improvements are invented several times over by inventors who are not familiar with what has already been

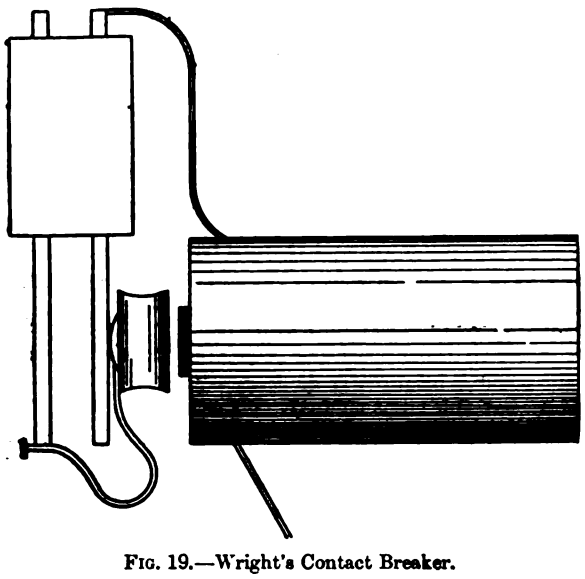

FIG. 19.—Wright's Contact Breaker.

done. We find in Sturgeon's *Annals of Electricity*, Vol. V., p. 30, a description of a coil by Thomas Wright, of Knutsford, dated 1840, in which he gives a sketch of a neat form of vibrating contact breaker (*see* Figs. 18 and 19), which is practically the same as that used on all small coils at present. Wright followed Neef and Wagner in suggesting that the contact points should be tipped with platinum. He succeeded in making some "electrotomes," as they were called, in which the spring vibrated so fast as to give out a musical note. Wright also gives details of many coils made by him about this time to determine the best dimensions of the core and of the circuits. It will be seen that by the year 1840 the induction coil had been practically completed in all essential parts, with the exception of the condenser. The separate primary and secondary circuits of thick and thin wire, the divided iron core and the vibrating contact breaker had been arrrived at and perfected; chiefly by the investigations of Callan, C. G. Page, Sturgeon, Backhoffner, Wagner, and Neef.

§ 11. **The Researches of Masson and Breguet.**—Between 1838 and 1842 the French physicists, MM. Masson and Breguet, prosecuted researches of a valuable character on the induction of electric currents. In the *Annales de Chimie et de Physique* (3rd Series, Vol. IV., 1842, page 129) will be found a long memoir, summing up the results of their work, which was communicated to the Academy of Sciences on August 23rd, 1841.

This Paper contains an account of very careful experiments on the production of electrostatic effects by secondary induced currents. In their investigations, Masson and Breguet employed a toothed wheel interrupter, or rheotrope, consisting of a brass toothed wheel having the teeth interspaces filled up with wood or ivory; one or more such wheels could be revolved on the same axis, and, by means of springs pressing against the periphery of the wheels, the primary current could be broken, and the secondary circuit closed at instants corresponding to the closing or opening of the primary circuit.

By the help of this apparatus they could separate out the two induced currents, and by means of a condenser and electroscope they examined the electrostatic potential at various points on the secondary circuit. Not being aware of the previous researches of Page, these investigators were apparently under the impression that they were the first to show that a condenser could be charged from the ends of the secondary circuit. Transforming, as they called it, induced currents into static electricity, they produced luminous discharges in vacuo by means of induced currents, and showed that these discharges had all the characters of discharges produced by electrical machines or Leyden jars. These results surprised European physicists, who, as Du Moncel observes, were apparently not aware that similar experiments had already been conducted in America. Amongst the chief results of this investigation was the experimental confirmation of the fact that the two secondary induced currents, the one produced by the commencement of the primary current, and the other produced by its cessation, consisted of equal quantities of electricity set flowing in opposite directions. Also the other important fact that the maximum value of the electromotive force of the secondary current at break of the primary is much greater than the maximum value of the secondary current at the starting of the primary, was stated by them. Hence it became clear that the direct or break-induced secondary current could traverse air spaces or overcome resistance which was impossible in the case of the inverse or make-induced current. The researches of Masson and Breguet established on a quantitative basis more firmly than before the facts of the induction of electric currents, but they did not achieve more than had previously been done in exalting the spark-producing power of secondary coils.

§ 12. **Henley's Coil.**—In the years between 1842 and 1851 very little progress appears to have been made in improving induction coils. Some modifications of arrangement either of the coil or the contact breaker were introduced. To this period, probably, belong two such varieties which are mentioned and described by Noad (*Manual of Electricity*, Vol. II.). One of these is represented in Fig. 20. The primary coil consisted of about 35ft. of insulated copper wire (No. 21), and the secondary of 1,400ft. of silk-covered copper wire (No. 20). The battery contact is renewed and broken by the rotation of the soft iron bar, which, mounted between two brass supports, is situated immediately over the axis of the coil, in which is placed a bundle of iron wires. The current from the battery passes through the support and the axis carrying the iron bar;

* See *Pogg. Annalen*, Vol. XLVI., p. 107, 1839; † and *Pogg. Annalen*, Vol. XLVI., p. 104, 1839; and compare *Wiedemann's Galvanismus*, §§ 696 and 737.

Digitized by Google

and the contact is interrupted by the small steel point, dipping as the bar revolves into and out of the mercury contained in the brass cup mounted on the brass pillar, through which the circuit is complete. This apparatus formed a self-acting shocking coil, but could produce no sparks from the secondary. Noad describes also an interesting form of coil which bears some relation to Page's electro-magnetic multiplier, and which, Noad says, was given to him by Mr. W. T. Henley. It is represented in Fig 21. A series of U-shaped bars of soft iron bolted

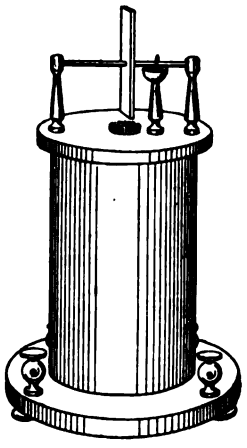

Fig. 20.

down to a base board was wound with four coils of No. 14 covered copper wire, to within an inch of either extremity. Over this was wound 1,000 yards of No. 34 silk-covered wire in one continuous length. A revolving iron armature rotates on a vertical spindle, so that in passing over the magnetic poles it nearly completes the magnetic circuit. The contact breaker consists of a bent lever, one end of which dips in a mercury cup and is so pivoted that the motion of the other end against the undulating surface of a cam-wheel attached to the spindle serves to dip the first-named end in and

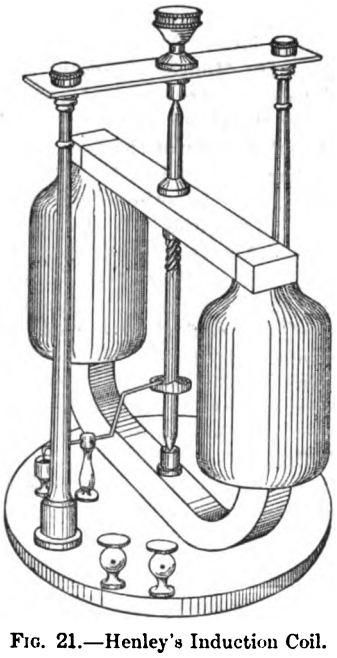

Fig. 21.—Henley's Induction Coil.

out of the mercury. The break of the primary circuit is so adjusted as to take place just after the soft iron armature has completed the magnetic circuit. Actuated with a battery of 10 cells this coil gave sparks one-eighth of an inch long in air, and remarkable for their quantity. It is easily seen that the appliance is, at the same time, an induction coil and also an electro-magnetic motor, and that a suitable arrangement of the time of making and breaking the primary circuit will cause the soft iron armature to be kept continuously in motion. It was noted as a curious fact that when the ends of the secondary circuit were metallically joined the spark at the primary break was much reduced. This is obviously due to the fact that the closing of the secondary circuit reduces the self-induction of the primary coil. These pieces of apparatus formed no real advance on what had been done before.

(To be continued.)

ELECTRIC AND MAGNETIC THEORIES.

BY SILVANUS P. THOMPSON, F.R.S.

§ 1. As Mr. Sprague has called in question the method of my argument, which I took the pains to explain beforehand in § 2, so that no one should have any ground to accuse me for laying a pitfall, I begin my rejoinder by quoting a few lines from Mr. Sprague's reply, p. 188, § 2.

"The real point in debate is how energy is transferred by an electric *current*. I ask him, has he *any evidence* of a single case of lateral transfer during the existence of true current? It is notorious that there is no scrap of evidence."

"He has dealt (in the way of evidence) solely with the phenomena of the variable periods."

"Therefore he avoids this difficulty by a logical dodge. He says, practically, if I can show that there are *some* cases in which we must agree that energy is transferred through the medium, I am entitled to assert that it is so in all cases. Bad logic and worse science."

Now, without admitting for a moment that I resorted to any "logical dodge," or argued with bad logic and worse science, I will at once say that I entirely agree with the first four sentences that I have quoted. There is *no evidence* (and I said as much on p. 44) *during the steady flow of the current* that the energy is transferred *laterally* across the medium. Neither is there any evidence during the steady flow that the energy is transferred along the wire *longitudinally*. The simple fact is that the current in the case of unvarying flow gives *no evidence at all* of the mode of propagation of the energy, and, therefore, in the present state of science affords no basis for an argument either way, in favour of lateral propagation or in favour of longitudinal.

Under these circumstances what can we do, in default of any crucial proof, to discover how the energy is propagated? The only course is that which in every branch of every science has proved the key to discovery, namely, argue forward from the known to the unknown. Find a case in which direct evidence exists, and argue on from this to those cases in which we have not yet been able to find direct evidence. If this procedure is to be stigmatised as a "logical dodge" then I fear that most of the advances of science during the last century must be set down as the result of logical dodges also. To argue from the known to the unknown, and then to test the result by probing to the bottom the necessary consequences of the step, is the one true scientific course in such a dilemma.

What did I say at the outset, on page 44? "Since in those cases in which the hypothesis of lateral transfer cannot in the present science be directly demonstrated, there is no evidence to show that the transfer takes place in any other way, then *in the absence of such evidence* one is logically driven to the conclusion that in all cases the mode of transfer is the same as in those cases in which a direct demonstration is possible." Is not that simply a statement that I proposed to argue from the known and demonstrable to the unknown and yet undemonstrated? A "dodge" it is not; it is a legitimate proceeding, both logical and scientific.

§ 2. Mr. Sprague denies the legitimacy of arguing from the cases of variable currents to that of steady currents. He virtually says that, when looking for evidence of the invisible mechanism by which a current is sustained, we have no business to regard any evidence derived from altering the strength of the current. Why does he lay down any such short-sighted limitation? If I want to find out whether a leak of gas comes from a certain pipe, must I refuse to make such

Digitized by Google

simple experiments as turning off the main supply, or turning it on more fully? To tell me that I am not to apply any evidence except that derived from considering the gas supply in its steady state is absurd. There are many things in science which in order to measure them *must* be changed. How can you find out the energy of rotation of a spinning body except by changing the rate of its rotation? To tell me that I am, in considering the problem, to be debarred from any evidence that is based upon altering its rate of rotation, is an insult to common sense.

I fail to see why, Mr. Sprague, reject, refuse, and exclude as irrelevant the overwhelming evidence that when the current is being varied the energy which propels that current comes in laterally from the medium.

§ 3. Mr. Sprague has fallen into a serious misunderstanding of the cases presented by me in Figs. 1 to 5. I have never said, or suggested, that in Fig. 1 (or any other of the figures) the energy travelled from the source S *along the wire* to the primary coil A in order thence to travel across the medium to B. In order not to confuse the issue then under discussion, I expressly said nothing in the description of that figure as to the precise mode in which the energy travelled from S to A. My point was that, however it got to A, which I was not then discussing, it undoubtedly and beyond cavil passed from A to B by the medium. So § 5 of Mr. Sprague's reply, on p. 188, is founded on a misconception. In § 6 he proceeds to argue that in these very cases the energy flows across the medium along the magnetic lines; and he proceeds (to use his own elegant phrase) to "knock the bottom out of my tambourine" by informing me that the magnetism accounts for it all. Well, but unfortunately the energy moves, as can be directly demonstrated on even Mr. Sprague's views, to say nothing of mine, transversely to the magnetic lines, not along them. Else how does the energy get from a coil surrounding a bar of iron that lies in its axis? And, moreover, the magnetic lines in the medium are a part of the physical properties of that medium, and have no existence apart from it. And the energy paths in the medium are, after all, just as real entities as the magnetic lines are, though not so familiar to us.

§ 4. Time was when we did not know how to prove the paths of the magnetic forces in a medium: the iron filings experiment is now most familiar. Time was when we did not know how to show the paths of flow of electric current in a sheet of tinfoil: this also is now a matter of simple experiment. Time was when we were ignorant of the paths of the lines of electrostatic stress in a dielectric; but Faraday showed us how to explore them with bits of silk in turpentine; Maxwell with suspended threads; Kerr by their action on polarised light. Even now some people can't see the evidence for them, or don't understand it; and time was when we did not even know that there were any energy paths, much less learned their direction. We know that direction now in general terms, but we are as yet ignorant of any experimental mode of demonstrating them. I observe that, in § 15, p. 190, Mr. Sprague blandly suggests to me that I should "prove" their existence by applying polarised light to a pan containing bisulphide of carbon. That experiment would be about as useful as it would be to explore a magnetic field with bits of silk in turpentine, or to measure the brightness of a light by listening to it through a stethoscope. The experimental method of observing the energy paths in the case of steady flow has yet to be discovered. At present, we can only argue from the known to the unknown. By the way, it seems to me that Mr. Sprague must be confusing the energy paths with the electrostatic lines of stress, for it is the latter which produce optical phenomena in polarised light.

§ 5. Many of Mr. Sprague's replies are mere inversions of previous argument: for example, §§ 7, 8, 9. These and others equally inconclusive I must pass by, to come to more vital matters, ere my allotted space be filled up.

§ 6. In § 13, p. 190, Mr. Sprague asks me about Fig. 8, and the energy paths from source to sink. He suggests that if the part 5—6 on the wire is the "sink" for the energy from the part 5—6 of the "source," the transfer of energy between these parts should go on equally well if the other parts were cut out. I also say, why not? Cut out the parts below 5, 5, by immersing all the lower part in quicksilver, and I say that even then the energy will still flow across from 5-6 in the "source" to 5-6 on the "sink," independently of the other parts.

§ 7. In § 20 Mr. Sprague suggests to cut off the flow of energy in my Fig. 9, by surrounding the central wire with a "total reflector" of energy. As a total reflector of energy is yet undiscovered in science, I am unable to comply with the request. One other thing he omits in that paragraph. If a screen or reflector—I suppose he means a metal tube—were put around the central wire its presence would alter the energy paths, not cut them off. For he forgets that the energy paths are always in the equipotential electrostatic surfaces.

§ 8. In § 18, p. 218, Mr. Sprague remarks that the term "end-thrust" is not his term at all. I am not sure whose the term may be; the essential idea is his. His turbine which propels the water in his hydraulic diagram certainly works by end-thrust. He says also, on p. 218, that he has nowhere suggested that what we call electric current is a motion of translation. Then why the turbine or the pipes? What can be more emphatic than Mr. Sprague's dictum:—"I say that the conditions of the electric current and the hydraulic current are identical in principle"? He speaks (p. 575) of "drawing in the water at one end and forcing it out at the other," and calls this "the most perfect analogue" to an electric current. That is perfectly clear and plain—at least I thought so. Accordingly, I showed that this most perfect analogue, which certainly works by end-thrust, produces stream-lines quite different in form from those of the electric current. This was a plain piece of evidence that the perfect analogue was a false analogue. Yet now it appears, from § 18, p. 218, that Mr. Sprague repudiates his former proposition, and says that he has never said that there was any end-thrust, or any actual transfer along the pipe (*i.e.*, motion of translation). Well, then, if there is not to be any transfer along the pipe by end-thrust, and if the pipes which, on p. 730, are called elastic pipes are now not to be elastic (for I observe that when I ask about this "perfect analogue," whether the copper conductors of an electric current swell up or contract, Mr. Sprague resents the query as not being "criticism"), what becomes of the perfect analogue? I fear the perfect analogue has landed its author in a mass of contradictory conditions.

§ 9. Last of all, why does Mr. Sprague persistently ignore the Hertz experiments? Does he not like direct evidence? "I am not going to be led off into Hertz experiments just now," he says. Precisely so. He ignores the most striking evidence that electric energy can be, and is, conveyed by the medium. That is where we differ. He declines to discuss the evidence that points with overwhelming certainty to the imperfection of the views he advocates. It is really no affair of mine if Mr. Sprague chooses to put aside, as though of no importance, the experimental work of Hertz. By so doing his own position is weakened far more than by anything that I have written, or could write. Mr. Sprague is quite welcome to have the last word in this discussion, even if that word be to say that in Hertz's experiments there is not a steady-flowing current but only oscillations of currents. The evidence exists: the only real question left is whether we will close our eyes and ears and shut it out, lest it should afford a basis for arguing from the known to the unknown.

ON THE MECHANICAL ACTIONS OF ELECTRICAL WAVES PROPAGATED IN CONDUCTORS.*

BY H. HERTZ.

The study of the forces to which a conductor is subjected when placed in the path of a series of electrical waves, seems to me interesting for many reasons; among others, because these forces, when strong enough to be observed, enable us to study the waves quantitatively. I hoped to find in the nature and distribution of the mechanical forces a means of showing the existence of the magnetic force at the same time as that of the electric force.

* Translated from *La Lumière Electrique*, March 28, 1891.

Digitized by Google

In all the experiments hitherto made, the electric force alone has been manifested†, and as ordinary means do not demonstrate the magnetic force, it is of interest to study new methods with this purpose in view. I had an additional motive which formed the special aim of my research, and this arose from my hope of making observations of the waves in air under circumstances in which the movements produced could not be in any way attributed to forces acting at a distance. Owing, however, to the feebleness of the actions produced under these circumstances, I have failed in this endeavour, and have been forced to content myself with the study of the waves propagated in wires, although in so doing the principal interest of the experiments disappears. The mechanical action of waves propagated in wires can be attributed to the attractions of the quantities of electricity which accumulate on the wires, and to the currents which flow within them, and experiments made on these waves cannot thus serve as a crucial test between the old and new modes of regarding the phenomena.

The System of Waves Employed.

After having studied various dispositions of apparatus, and obtained results which were quite concordant as regards the principal points at issue, I resolved to adopt the method of Mr. Lecher as being the most appropriate. Fig. 1 indicates the form of the apparatus. A A′ is the primary conductor, formed of two square plates of 40 centimetres side, joined by a brass wire 60 centimetres long. This wire is interrupted in the middle of its length, where the spark gap is placed. A small induction coil is used as exciter, worked by two accumulators, and producing sparks four centimetres long. The simple discharge of this little coil is certainly less powerful than that of a larger one, but the rapidity of the discharges compensates for the defect.

Facing the plates A A′, at a distance of 10 centimetres, are the plates B B′ attached to two parallel wires B b, B′ b, placed at 10 centimetres from each other. These wires are each 6·8 metres long, and their ends are connected at $b\,b'$. At a distance B a, which is variable, the two wires are also connected by a bridge piece $a\,a'$. For a certain position of this bridge, at a distance of about 1·2 metres from B B′, a very energetic oscillation is produced at $a\,a'$ and $b\,b'$. This represents the half length of a stationary wave, and, as Mr. Lecher has shown, it is produced by resonance between this vibration itself and the primary vibration produced in the air, between A A′ on the one side and B $a\,a'$ B′ on the other. A displacement of the bridge augments the period of one of these vibrations, and at the same time diminishes that of the other, so that with this arrangement the proper position of the bridge is determined in a very precise way.

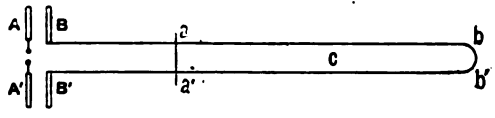

Fig. 1.

Besides these general advantages, the method also offers several special advantages for the purpose we have in view. As the forces to be observed are very small, it is necessary to carefully eliminate, as far as possible, all extraneous electrostatic actions due to the presence of conductors. This can be done with the disposition already indicated, as the wires, which it is necessary to bring near the bodies under test, form a system of continuous conductors. If in our experiments we surround the active parts with a metallic cage in connection with the nodal points $a\,a'$ and $b\,b'$ we shall protect them still more completely, without altering the vibrations.

As the conductors which we submitted in turn to the action of the forces did not, like the resonators previously used, choose a vibration of fixed period from among the oscillations produced, the results obtained, in the first instance, were confused, until care was taken to produce a simple oscillation, whose wave length was perfectly definite, and which had its nodes in a strictly determinate position. In the above arrangement this condition is satisfied, for no one can doubt that the points $a\,a'$ and $b\,b'$ are the nodes of all the vibrations produced, and that among these vibrations the slowest only are reinforced sufficiently to attain an appreciable intensity. The fact that we confine ourselves to the study of the half of a wave length does not in the least detract from the generality of the experiments. Finally, the vibration is of the same character whether the two wires are stretched out straight, or whether they lie near to one another, or curved in any way; just as the sonorous vibrations of air in tubes are the same whether the tubes are straight or bent.

We can thus easily make our vibration have all possible positions relatively to the body under test, although the latter is kept fixed. In fact, the relative positions in the experiments were always altered by moving the wires, even in cases where, for convenience, I speak as if the body under test had been moved.

† When I have formerly referred to the nodal points of the magnetic waves, it was only on theoretical grounds, and not from actual observation.

The Electric Force.

For the measurement of the mechanical action of the electric force, I have used a little cylindrical tube of gilt paper 5·5 centimetres long, and 0·7 centimetres in diameter. This tube was suspended horizontally by a thread of silk. A minute magnet was affixed for controlling purposes, and a small mirror was used to indicate the deflections. The entire system was suspended in a little glass box, and is indicated in Fig. 2. When it is submitted to the influence of the vibrations, the tube deviates and tends to set itself in the mean direction of the electrical force. To obtain greater deflections, I brought the two wires near together in the neighbourhood of the apparatus, and reinforced their effect near the extremities of the body tested by two small plates, as Fig. 2 indicates for a special case. Under these circumstances it was possible to obtain initial swings of over 100 scale divisions.

The regularity of these first swings was satisfactory, for on repeating the same experiment several times the results obtained did not differ from each other by more than a few per cent. As examples of the possibility of applying these deflections to purposes of measurement, I indicate two series of observations. The first shows the action of resonance. The apparatus was placed at c, the antinode of the vibration, and the wires $a\,b$ and $a'\,b'$ were brought near one another, as indicated in Fig. 2. The bridge piece $a\,a'$ was then placed at different distances e, measured from B B′, the induction coil was set working, and the value of i, the first

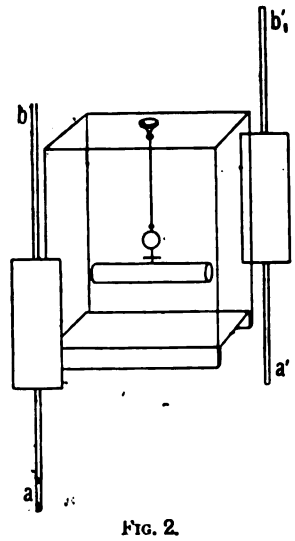

Fig. 2.

swing, was observed. The corresponding values of e and i in the neighbourhood of the maximum were as follow:—

e	8,	90,	100,	110,	120,	130,	140,	150, 160 cm.
c	5·3,	10·0,	21·8,	51·2,	44·1,	19·3,	10·3,	5·7, 4·2 divns.

If these values are plotted, the curve connecting them is quite regular, and shows a well marked maximum between 110 and 120 cm. As a matter of fact, the impulsive swing reached a maximum value, $i = 60·6$ divns., for $e = 114$ cm.

The second series of tests was made with the view of showing the diminution in the intensity of the vibrations from the antinode c to the node b. For this purpose, the distance between them was divided into 12 equal parts, and the apparatus was successively placed at the 13 points of division so obtained. The following observations were made:—

No. =	1	2	3	4	5	6	7
i =	80·5 ...	80·5 ...	79·0 ...	77·0 ...	65·0 ...	57·8 ...	50·0
No. =	8	9	10	11	12	13	
i =	38·5 ...	27·5 ...	17·5 ...	7·0 ...	1·0 ...	0	

These values vary in a sufficiently regular manner for the purpose of judging the form of the vibration, and for making it evident that it differs in a very noteworthy way from a simple sinusoidal oscillation.

Other experiments I have made show the direction of the electrical force in the neighbourhood of the wires. The results are only such as would have been expected. In the space between the wires the needle tends to set itself along the line forming the shortest distance between them. Outside this space the needle tends to set itself perpendicular to the nearest wire. The extremities of the little tube seem thus always to be attracted towards the nearest portion of the wires.

The Magnetic Force.

For studying the magnetic force a circular ring of aluminium wire was used. The diameter of the ring was 65 millimetres, and that of the wire two millimetres. The ring was suspended so that it could turn about one of its diameters, and was furnished, like the cylinder previously mentioned, with a magnetic needle, a mirror, and a glass cage. Fig. 3 shows the arrangement of the apparatus.

If for a moment we disregard the magnetic forces which we know to exist, we should expect that the ring, under the influence of the oscillations, would behave like the cylinder already described ; and that the parts of the ring farthest from the axis of rotation, or the extremities of the horizontal diameter of the ring, would move in the same manner as the ends of the cylinder. We should also expect that the ends of the horizontal diameter would always be attracted towards the nearest portions of the wire by means of which the electrical oscillations are being propagated ; and that these actions would be most marked at the antinodes of the vibrations, and would disappear in the neighbourhood of the nodes. As a matter of fact, if the ring is actually suspended at the nodes $b\,b'$, as indicated in Fig. 3, the phenomena observed are quite different. In the first place, the ring does not remain at rest under the influence of the oscillations, but is acted upon by forces of the same order of magnitude as those evidenced by the action of the cylinder when placed at the antinode of the vibrations. Moreover, the direction of the deflection shows that the force between neighbouring parts of the ring and cylinder is not an attraction, but a repulsion.

The repulsion is due to the oscillations, and its magnitude must depend on resonance, according to the same law as the electrical actions. The ring always sets itself perpendicular to the plane of

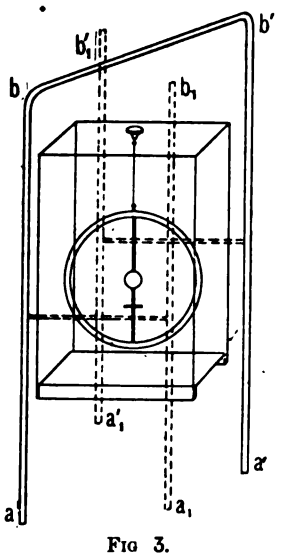

Fig 3.

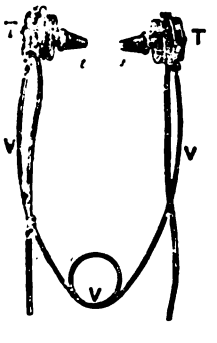
the wire, whatever its position with reference to it, provided it lies within the contour $b\,b'$. We can deduce, therefore, from these experiments alone that, in addition to the electrical vibration, there exists a vibration of another kind whose nodes coincide with the antinodes of the former, and that the directions of the two classes of vibration are perpendicular to each other. Referring to the experiments, we can easily recognise the new vibration as magnetic. The rapidly oscillating magnetic force must, by induction, produce a synchronous alternate current in the closed metallic ring, and the reaction of this current produces a deflection. The magnetic force is a maximum at the nodes of the electric vibration, and at these points its direction is normal to the plane of the wire, That the action between neighbouring portions of the ring and wire is a repulsion is easy to account for. The current induced in the ring is such as to neutralise within the ring the effect of the inducing current in the wire. The two currents accordingly flow in opposite directions and repel each other.

The other phenomena observed with the suspended ring can, without difficulty, be explained by the theory just given, although complications are sometimes introduced. Thus, for instance, with the arrangement indicated in Fig. 3, if the ring is moved away from the node b towards the antinode of the vibration, the repulsion diminishes very quickly, becomes nothing in a certain position, and then becomes an attraction increasing in amount until the antinode is reached. In a particular case the repulsion deflection at $b\,b'$ was 20 divisions, it disappeared altogether at about 95 centimetres distance from the ends, and became an attraction, the maximum value of which was measured by 44 divisions. In order to explain these results it is necessary to consider the simultaneous action of the electric and magnetic forces, the former being greatest at c, and the latter at $b\,b'$. We can verify this explanation by investigating the variation of the magnetic force after having eliminated the action of the electric forces. With this view place parallel to the wires $a\,b$, $a'\,b'$, two other wires of about 20 centimetres length, arranging the four wires symmetrically with regard to the equilibrium position of the ring, as indicated by the dotted lines in Fig. 3. Also join $a\,b$ to $a_1\,b_1$ and $a'\,b'$ to $a_1'\,b_1'$. In this way the electric action is evidently almost annulled, while the magnetic action is very little altered. We now observe a repulsion of the movable ring for all distances, diminishing to a minimum at the antinode of the electric vibrations. The minimum value is found to be four divisions. If the electric vibration were sinusoidal, the magnetic force would have disappeared at the node. The distribution of the electric force has already shown us that this hypothesis is not exactly correct, and we can thus understand the existence of magnetic force even at the antinode. The mechanical actions of the electric and magnetic forces, as theory indicates, are in general of the same order of magnitude. The predominance of one or the other depends essentially on the mutual actions of the nearest parts of the ring and the solid conductor. The more nearly these are like infinitely short wires, the greater is the relative importance of the magnetic force ; while the greater the surface of the conductors, the more the electric force predominates. From the above experiments on conductors of very simple form, it is evident that a conductor of any form, when placed in the path of a train of electro-magnetic waves, is subjected to forces of a very complex character.

ON A SMALL AND LIGHT TELEPHONIC RECEIVER, KNOWN AS THE BI-TELEPHONE.*

BY E. MERCADIER.

As a result of my experiments on telephonic effects, especially those of which particulars were given recently (*The Electrician*, Jan. 23, Feb. 20, 1891), I have been led to the following conclusions:—In a telephone which acts as a receiver it is possible to obtain, simultaneously, clearness in the reproduction of the various inflexions



of articulate speech and the loudness necessary for all the requirements of the telephone. For this purpose it is only necessary that the diaphragm should be thick enough to absorb most of the lines of force in the field of the magnet, and secondly to decrease the diameter until the fundamental note and the harmonics of the diaphragm are more shrill than those of the human voice, that is than the fifth octave of C.

It will be found that, in complying with these two conditions, we can get, with telephones having a very weak magnetic field, results which compare well in loudness, and which are more distinct than with instruments having a stronger field, and consequently more weight and of much larger dimensions.

It will be, on the one hand, readily understood that we can take small magnets divided into two branches, or even one only, like those of the early Bell telephones, with coils correspondingly small, thus reducing the weight of this portion to one-fourth of what it originally was, and also reduce, as I have shown above, the thickness and more especially the diameter of the diaphragm, resulting in a diminution in the size of the case in which it is fixed, and, secondly, the thickness of the diaphragm, and rendering it possible to replace the metal cases by ebonite, rendering the instrument still less weighty.

Having found it necessary in certain electrical researches to make use of telephones which would serve as very sensitive electroscopes, it occurred to me to use the foregoing results to construct a very light telephone, which could rest in the ears all day long and leave the hands entirely free.

I have designed several instruments of this kind, using telephones with either one or two poles joined by a spring of steel

* *Comptes Rendus*, 22nd June, 1891.

Digitized by Google

wire, V, 2mm. in diameter, as shown in the figure, and to this I have given the name "bi-telephone." The case is of ebonite, the lid terminating in gutta-percha tubes, *t t*, which can be withdrawn and changed at will (each operator having his own tubes for his own personal use). The tubes enter the ear and press lightly on the aural canal, kept in place by a twist previously given to the spring. The spring passes under the chin of the operator, and the pressure may be regulated by pulling the two branches of V more or less apart. As these instruments only weigh 50 grammes (1·76 ounces) as compared with an ordinary telephone, which weighs about 400 grammes (14 ounces), and do not exceed 3 to 4cm. (1·17 to 1·56in.) in diameter they produce neither fatigue nor even inconvenience after several minutes' use.

The steel spring may serve to connect electrically two of the four ends of the coils, so that two wires will be sufficient to connect the telephones with the instrument with which they are being used. This spring may also be strongly magnetised, and help to strengthen or maintain the magnetism of the telephonic magnets, thus serving three purposes—mechanical, electrical and magnetic.

Bi telephones thus designed for scientific purposes have been tried as receivers with ordinary microphone transmitters on telephonic lines; for instance, underground lines, 50 to 75km. (31 to 46 miles) in length, on a line 800km. (500 miles) long, and on the new London-Paris line. They have given good results, and have been adopted for use in connection with apparatus authorised by the Government for telephonic work.

These instruments are suited to all kinds of telephonic transmitters at present in use, and may be used by persons who have to take notes while transmitting or receiving messages or even writing them out entirely.

ON THE ELECTROMOTIVE FORCES OF GALVANIC ELEMENTS.*

BY A. OBERBECK AND J. EDLER.

As amalgams in which the percentage is pretty low behave, so far as electromotive force is concerned, almost exactly as the metals themselves, an element consisting of the combination: mercury | electrolyte | amalgam was chosen, and the E.M.F. determined by the compensation method with the aid of a mirror galvanometer. The tests included the metals zinc, cadmium, tin, lead, and bismuth, in a large number of solutions of sulphates and chlorides of various degrees of concentration. In the result it appeared that the electromotive force depends principally on (*a*) the metal forming the electrodes; (*b*) on the electro negative constituent of the solution.

The order of the metals in the solutions always remains the same, although their positions approach and recede from one another. The same is also true for free acids. The electromotive forces are greatest (and nearly equal) for sulphuric and nitric acids. For hydrochloric acid they are much smaller and nearly equal to those obtained with a neutral chloride. For solutions of salts the values of the E.M.F.'s follow the order: sulphate, nitrate, carbonate, chloride, bromide, and iodide. The electromotive forces only depend upon the metal of the salt in solution, when this metal is the same as that of the electrode. In this case the E.M.F. is smaller. If these results are compared with those published by J. Thomsen on the heat equivalents of the above metals (except bismuth), a distinct correspondence between the differences of these equivalents and the observed electromotive forces will be noticed.

The authors arrive at the following conclusions:—

1. The E.M.F. is to be calculated from the heat equivalent of the chemical process, taking into consideration the local evolution of heat that takes place at the electrodes.

2. Want of constancy in elements is due to the taking up of molecular layers of a dilute solution of the metal of the electrode. The degree of concentration depends upon many circumstances, which must be the subject of future experiments.

* *Wied. Ann.*, Vol. XLII., Part 2.

Mica.—The recent reported discovery of a great mica mine about 1,300 miles north of Adelaide seems to have been somewhat exaggerated. Mr. H. Y. Lyell Brown, the Government geologist, went to see the mica, and was surprised to find only a long pit, about 6ft. in depth and about 60ft. in length, from which nearly all the mica had been taken. There was no appearance of any continuance of the deposit. Only about three tons of mica in all have been dispatched from the mine.

A PORTABLE FORM OF CAPILLARY ELECTROMETER.*

BY A. BERGET.

This instrument does not possess any essential novelty. The marvellous apparatus of Mr. Lippmann was, in fact, complete when it first appeared, and its author has left no room for further development. The model which I have made only differs from the original in the arrangement of its parts, the object of the new design being to render the instrument transportable. The delicate part of a capillary electrometer is the glass point, and the chamber into which it dips. I have combined these two parts into a single piece, represented full size in Fig. 1. The following is the description of this portion of the instrument.

Fig. 1.

The glass chamber, A, terminates below in a bulb, M, containing mercury, which can be brought to any given potential by means of a platinum wire, *m*, fused into the glass of the tube. Its upper portion is fused into a tube, M', of the same diameter, full of mercury, and terminating in a capillary point *p*. A second platinum wire, *m'*, renders electrical connection possible with the mercury inside the upper reservoir. A very small hole, *o*, pierced in the glass tube A, near the point of fusion with the upper tube, is useful for the introduction of the mercury and the acidulated water, while, at the same time, it ensures that the liquid is under atmospheric pressure.

The entire apparatus is represented in Fig. 2. The capillary point and the reservoir are seen at E, on the plate of the microscope, M, used for observing the indications. In order to apply pressure to the mercury, M', so as to make it penetrate the point *p*, two glass reservoirs, R and R', united by a caoutchouc tube, C, are employed. These reservoirs are supported at different heights from a metal upright, *c*, *c'*, *c''*. The pressure at R is measured, in mercury units, by the difference of level of R and R'. This pressure is transmitted by air compression through the caoutchouc tube, H, to the mercury, M', of the electrometer. The reservoir, R', is fixed, while the level of R is adjusted by hand until the meniscus appears in the capillary tube and near the end.

The terminals, P, are clamped by a screw, V, to the lid of the box, B, into which the whole apparatus can be packed, and which also serves the purpose of a support. The metal column, *c*, *c'*, *c''*, divides into four parts, each about a quarter

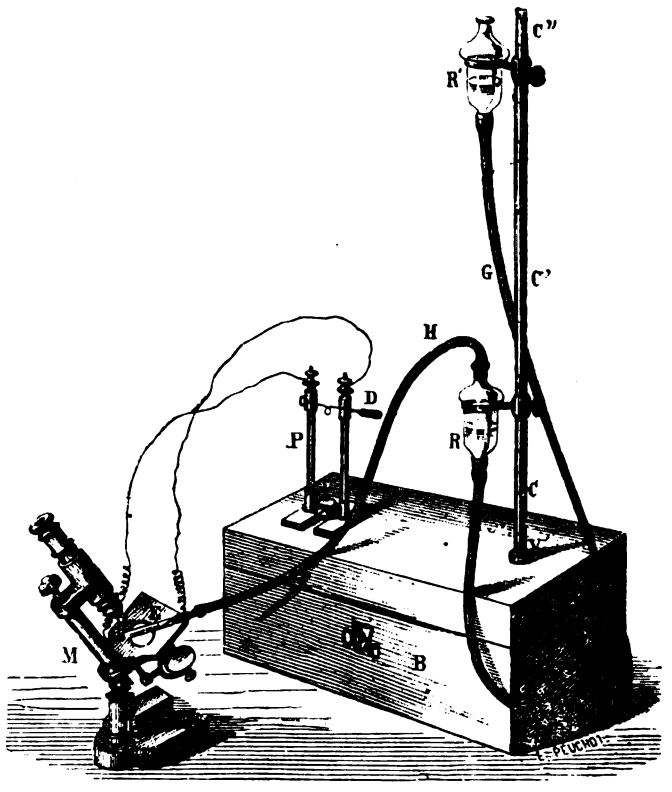


Fig. 2.

of a metre long. The microscope, M, specially constructed by Mr. Nachet, magnifies 300 times. The other parts of the instrument have been very skilfully constructed by Mr. Victor Chaubaud.

* Translated from the *Journal de Physique*, for May, 1891.

THE PROGRESS OF ELECTRICITY.*

I have the pleasure this morning of bringing before you the subject of the relative merit and cost of gas and electricity for lighting purposes. I propose to consider the subject solely from a practical point of view, and to deal rather with the financial aspects of the question than the mere technics. Of course, I shall have to deal a good deal with figures, and figures are proverbially dry. It has been said that you cannot extract a joke out of figures, and that you can always manipulate figures to suit your own particular view. Neither statement is quite true, because we have all of us heard the old story about the two men contesting with each other, and one man saying, "Why, sir, it is as plain as 2 and 2 make 4;" and the other man saying, "But 2 and 2 do not make 4, 2 and 2 make 22." And, again, as to manipulating figures to suit one's own purpose, I daresay it will be said I am going to do very much that kind of thing myself. But I am addressing you—if I have any prejudice at all—I am addressing you as a gas shareholder, and not as an enthusiastic electrician. Comparisons of costs are generally fallacious, because the comparison depends so very much upon the point of view taken. The questions we have to decide are principally such as these: What is the capital involved in any particular industry, what the profit derived, and what has the consumer to pay? I am not going to bring before you any fanciful figures. They are published figures, they are figures you can get for yourselves, and you will be able to check the deductions I am going to make. Now, I have taken the case of Manchester for the simple reason that I have more authentic records of what is done in Manchester than I have of what is done in any other town. And from the records of the gas department in Manchester, it seems that one ton of coal in Manchester produces 9,611 cubic feet of 20 c.p. gas. I take Manchester, also, because it is above the average —20 c.p. gas is rather in excess of the average of the country, which is not more than 15. Well, since this is the quantity of gas produced by a ton of coal, it follows that 1lb. of coal will produce 4·29 cubic feet of gas; and if 4·29 cubic feet of gas is burnt per hour we get in Manchester an illumination of 17·2 candles. Now, in drawing a comparison between gas and electricity I must use one technical term which is now coming into general use, and will have to be understood by every engineer, whether electrical or municipal, that is, the term watt. A watt is the mechanical unit of power which is exerted by a current, one ampere flowing through one ohm for one second. It enables us exactly to tell you how many lamps will be lighted and what light they will give. So, in the use of electrical energy, if we burn in a steam boiler 7lb. of coal, we shall 1·3 H.P. of electrical energy, but represented in watts we shall 1,000 watts, and a 1,000 watts is called a kilowatt, so 7lb. of coal will give us kilowatt-power of energy, and I will show you what light it will give. In the same way as I have shown that 1lb. of coal distilled into gas will produce 4·29 cubic feet, or 17·2 candles of light, so 1lb. of coal burnt in a boiler to produce steam will give us electrical energy that will give—I will show it in two forms, one the arc lamp, the other the glow lamp, which we use in our houses, 1lb. of coal burnt per hour, and used in electrical energy, if burnt in the form of a glow lamp, will give 48 candles, and if burnt in the form of an arc will give 288 candles. So there we start with the first theoretical fact that I bring before you, that 1lb. of coal distilled into gas in Manchester gives us a candle-power of 17·2; 1lb. of coal, if converted into electrical energy in the form of a glow lamp, 48 candles, and in the form of an arc 288 candles. That is theoretical. We will now come to hard facts.

In Manchester, during the twelve months ending March 30, 1890, the income derived from gas was £434,351, the expenditure was £360,804, showing that in Manchester a balance of £73,549 was derived from gas. That balance was devoted to meeting interest on loans, depreciation of plant, and the cost of public lighting. But from that fact I derive this: that the cost per 1,000 cubic feet of gas to the Corporation of Manchester was 2s., therefore it costs the Corporation of Manchester 2s. to produce 4,000 candles of light. Well, now, I am obliged to use an estimate for the simple reason that at present the Corporation of Manchester have not established a central electric lighting station. They have obtained a Provisional Order so as to enable them to do this, and they are now considering whether they shall carry it out themselves, or transfer their power to another body. In making an estimate of the cost of electricity in Manchester, we have to take the experience of the cost of manufacturing electricity elsewhere, and on this point there is, perhaps, more reliable, accurate, and truthful facts than with, perhaps, anything else connected with electricity. The Board of Trade exercise such a powerful control over the electric lighting interest that there is no hankey pankeying with the accounts. The accounts of expenditure must show the cost of production, and these are within the reach of everyone.

* A Lecture by W. H. Preece, F.R.S., before the Incorporated Association of Municipal and County Engineers, at the Institution of Civil Engineers, on Friday, 26th ult

My own experience of electricity is a pretty extensive one. We have a great many of our post offices lighted with the electric light, and I have a central station at the General Post Office, to see what we are doing; we have a very large plant, and we are going to produce in St. Martin's-le-Grand sufficient power to light 10,000 lamps, and we are laying down another plant at Coldbath Fields, where we shall generate electricity for another 10,000 lamps. From my own experience, I can say that we can produce a kilowatt or Board of Trade unit for 4d. It means that we can produce 4,000 candles by gas for 2s., we can produce 4,000 candles by the arc lamp for 8d., and we can produce 4,000 candles by a glow lamp for 4s. So you see on these facts—I am not calling them estimates, for they are ascertained facts—on these facts the theoretical estimate of light produced is twice as much by the glow lamp as by the gas lamp. These are theoretical estimates, they are not practical ones. However proud we, as gas engineers, may be of producing gas of 20 c.p., when you come to the houses and shops of users and consumers you find this 20 c.p. is very considerably diminished. This is a very important question, and one which some six or seven years ago concerned us in the Post Office very much, and Mr. Vernon Harcourt, F.R.S., and I devoted considerable time to experiments on this question. Mr. Vernon Harcourt, who is a very painstaking, careful, and accurate experimenter, found taking the ordinary burner, supposed to be consuming 5ft. per hour and giving 15 c.p., really gives only 10 candles, due partly to dirt in the burner, but due principally to the flickering of the light of the gas caused by draughts of air into the room. So, while a light burning in a special burner in a laboratory may give 15 c.p., when you come to a room or passage that lamp will only give 10 candles. This *pro ratâ* value is equally true of Manchester as of elsewhere. The result is you must add 30 per cent. to the cost of the gas for your 4,000 candles. There is another point. I ought also to say this depreciation in the value of light is not only true in the case of gas, but it is also true to a certain extent in the case of electricity. The lamps when they are still fresh and new will give 16 c.p. light, but after they have been used 200 or 300 hours the electricity flowing through the carbon filament that causes the carbon to evaporate, it flies away in straight lines, and is deposited on the glass bulb, obstructing a certain amount of light. Again, you have a certain amount of dirt and dust collected on the outside; the consequence is you have a depreciation in the amount of your electric light, though not quite so much as in the case of gas. I ought to mention, when drawing any distinction between the light-giving, whether electricity or gas, in the light given by each, that 5 cubic feet of gas will give, practically, 10 c.p., and 33 watts, in its normal power, will give you also 10 c.p. There is one element in gas that is a very serious loss indeed. That is the tremendous waste of gas that occurs through lights being left burning unnecessarily. Persons who have their houses and offices lighted with gas know that servants, as a rule, go and light all the burners, unless a careful householder goes round and cuts off those that are not wanted. The result is this: from this very element of waste there is 20 per cent. of gas used more than is necessary. It is brought out by this. Taking the nine principal towns in this country, and taking the average number of hours of gas and electricity burnt in this country, the average number of hours for gas is 600, the average number of hours for electricity is 460. This is taken from the average of 200,000 electric lamps which are now alight in London; while in gas you have a tremendous waste from these burners being left flaring, you have no waste from electricity. Electricity is so easily lighted, a tap turns it on and off, that there is a species of instinct that teaches everyone, that you only want your electricity lighted in the place where you require, and the result is you get no waste. The result of it all comes to this, that the comparison between gas and the glow lamp is not 2s., as against 4s., which is theoretical, but the practical figure of 3s. 8d. We can prove this. The average amount, taking the returns from the chief nine towns of this country, paid per gas burner per annum, is 9s., while the average price of gas is 3s. per thousand feet; the average price of the 200,000 electric lamps burning in London is 10s. So we have these two facts, that the average price paid by the consumers for gas is 9s. per annum, the average price paid by the consumer to the electric light provider is 10s. This is rather a startling figure, because most people are under the impression that the cost of the electric lamp is very much greater than gas, and I have been myself very much surprised to find that the price I pay in my own house, where I generate my own electricity, and have done so for the last eight years, was so very small. I find, although I have a gas engine and accumulators, and have over 70 lamps in my house, I am not paying more than when I used gas. I have taken all the companies in London, and have tabulated the revenue derived by each company per lamp per annum, for a 33 watt light and a 10 candle burner, and I find that the Metropolitan Electric Supply Company derive a revenue of 12s. per lamp, the Chelsea Electric Supply Company 8s. 6d. per lamp, the Kensington and Knightsbridge Company 9s. 2d. per lamp, the House-to-House Electric Supply Com

Digitized by Google

pany 11s. 6d. per lamp, St. James's and Pall Mall Electric Supply 9s. 6d. per lamp, and a company in Brighton charges 8s. 6d. per lamp; the mean being, for 200,000 lamps, 10s., which compares with 9s. for gas. Well, I have also verified this ratio between the two lights, and in the General Post Office, where we burn a great quantity, and where night operations are extended to late hours, and we begin at early hours, there, from the experience of two years' working and comparison, we find that gas costs 18s. per lamp per annum, and electricity 22s., the ratio being 9s. and 11s., and not 9s. and 10s. as with the companies. Take the case of Manchester, where gas is cheaper than in London. The average price paid per lamp for gas in Manchester is 7s. 6d. per annum. Well, taking the cost of electricity at 4d. per unit, the revenue that Manchester will derive from public lamps will be 8s. 4d. per annum, against 7s. 6d. for gas. Of course, the rates of charges vary very much in London; the private companies are charging 7d., in other instances 8d. per unit. In Bradford they commenced by charging 5d., and have since raised it to 6d. In Newcastle they are charging 4½d. to the public, and they are allowing large discounts on that, 4½d. to the large users of electricity. We in the Post Office are large users, and we have a discount of 20 per cent. off that 4½d., which makes the cost of our electric lighting in Newcastle very nearly approaching that of gas. In factories where they have isolated installations, all the facts show that electricity is cheaper than gas. I have figures from Bolton, from Messrs. Horrocks, Crewdson, and Co., who are amongst the largest employers of labour in that district. They have had the electric light going for six years, and while they were using gas the cost per lamp per annum came to 5s. 6¾d. Since they have generated their own electricity it comes out that their lamps cost them 4s. 4d. per annum, so there is a considerable reduction. Those who know Manchester know that under the Exchange there is a large restaurant, which used to be unbearably hot when lighted with gas. The manager, two years ago, replaced gas by electricity, and finds he has not only saved £800 a year in the cost of the light, but has probably doubled his income by allowing his guests to have their meals in comfort. So far as figures go, I have given you hard facts to show there is not much difference between electricity and gas. I tell all my friends that my house is lighted by gas; but I burn my gas in the garden, and allow all the vitiated gases to disappear in the air, while I extract from the gas what I want—light—and have it in my house. If you take 25 cubic feet of gas and burn it direct, you will only get 50 candles of light. If you burn your 25 cubic feet of gas in a gas engine, and produce electrical energy, it will give you 160 c.p. of light in the house. So, with a little care, you are able to still use the gas and treble the amount of light in the house.

I see in the programme you are going to the Royal Naval Exhibition. The Royal Naval Exhibition is lighted by electricity. There is an engine-room there fitted up with probably the latest developments of electrical machinery. Electrical machinery is constantly changing. We are daily producing improvements of some kind or the other. The electrical room there is well worth your visit, and you will see there how the electrical energy is generated, and will probably find that one dynamo and one engine is supplying light to the whole of the Exhibition. On Saturday you are going to have a still more interesting visit to the works of the Electric Supply Corporation, at Deptford. They are not complete, but there you will see preparations that are being made for lighting one million lamps in London. At the present moment they have only sufficient machinery to allow of 200,000 lamps going. You will find there the space required for electrical machinery to light a million lamps. One of the great merits of electrical machinery over gas machinery is the small space which it uses. Gas requires 100ft. by 50ft. for every million cubic feet made per annum; with electricity 100ft. by 50ft. is quite sufficient to light up one of our big towns. We must not neglect other points. We must not neglect the fact that when we deal with electric lighting we are removing from our midst a source of deterioration to our goods, chattels, and fixtures. Another point is, that it adds so much to the security of our buildings. It is not absolutely safe; it would be absurd to say it was. Carelessness and folly will cause fire by electric current as by gas. It requires supervision and the usual care which engineers know so well how to exercise. But it is this question of health which I want to thrust down everybody's throat as the great merit of electric lighting, if the price was very great indeed. We find in the Savings Bank Department of the General Post Office the cost of the electric light is paid for by the increased work we get out of our staff. The introduction of the electric light has diminished the hours of absence two hours per day per annum. That put down at 10d. per hour, which is the ordinary overtime rate in Government service, means we save £680 a year. Our electric light costs us £700, so it is really only costing us £20 a year. So in the General Post Office we succeeded in putting in the electric light just before Christmas, and the Chief Controller told me the electric light enabled them to get out their work quicker than ever before, and it was equal to 200 men. The purity of the air you breathe, the sanitary aspect of the electric light, is the point and aspect which commends it so much to municipal engineers and local authorities. We must not forget that when gas is let into the air the impurities in it are poisonous. Gas burned in a bedchamber is as injurous as bad water and bad smells. The chief duties of the Municipal Engineer have been to improve the sanitation of our towns, and to remove vegetable and decaying matter from our water supplies. But the duties of the Municipal Engineer will not be complete until he takes in hand the electric light. There is one other point I want to urge upon you, that is, that it is not the lamp of luxury. The common argument is that it is the lamp of luxury, that it is only the rich man who can afford to pay for it. The electric light is the poor man's light. If you can get the light for 8s. 4d. per lamp per annum, it is to the benefit of the working man, who has to live in small, ill-ventilated rooms, to have the light in his home. Now, the price of gas is going up; the price of electricity is coming down. The price of gas is going up from labour disputes and strikes; the price of electricity is coming down, because we know so very much more about it. We can produce 1,000 feet of gas for 1s. 10d., the extra 2d. is for management and collection, though I have no doubt that gas engineers will claim to be able to produce it for 1s. 7d., or 1s. 4d., or 1s. per thousand feet.

What can we produce electricity for? I have just been making a most exhaustive inquiry into the cost of electricity in the production of phosphorus and copper. They are two industries where the use of the current is continuous. You have your engines, dynamos, and everything working at its maximum efficiency. In electric lighting the load is irregular. People will not go to bed at the same hour, or rise at the same hour, so your load-line is variable. Where your load-line is constant, as in the production of copper and phosphorus, you can produce your electricity for one-third of a penny per unit. There is no mistake about that figure. The cost of production of a unit of electricity with a constant load is but one-third of a penny. What does that mean? If we take the theoretical difference between gas and electricity, it is equivalent to gas produced at 3d. per thousand feet. When we have the prospect of producing electricity at one-third of a penny, equivalent to gas at 3d. per 1,000 feet, it shows what a vast field of development is before the electric light. There is one reason why gas is still ahead of electricity; it is that there is such a market in this country for residuals. The price obtained for coke and ammoniacal liquors, and the other ingredients of gas works, practically reduces the price of coal in London to the gas manufacturers to 4s. 6d. per ton. We have to pay in London for Welsh coal 23s. per ton; that is why we have to pay more for the electric light than for gas. When we come to places like Gibraltar and Malta, where I went to see whether it was possible to use the electric light instead of gas, where there is no market for residuals, it required no difficulty on my part to say that it was possible to produce electricity cheaper than gas. I have endeavoured, to the best of my ability, to bring this matter before you as practical men, and I want you, if you agree with my conclusions, to point out to your different Boards that the duty of a Corporation is to look into this matter, not only from a financial but from a political as well as a sanitary, but, above all, from a philanthropic, point of view, and endeavour to persuade, as I have endeavoured to persuade you, that the electric light is not the light of luxury, but the poor man's lamp.

PHYSICAL SOCIETY.

At the meeting of the Physical Society, on Friday last, Prof. W. E. AYRTON, F.R.S., President, in the chair, the following communications were made:—

"The Construction of Non-Inductive Resistances."

BY PROF. W. E. AYRTON, F.R.S., AND MR. T. MATHER.

In making some transformer tests, about three years ago, the authors had occasion to consider the construction of electric conductors, the impedances of which should be practically equal to their resistances. This condition could only be fulfilled by making the inductance small in comparison with the resistance, and as the former does not depend on the material employed (excepting iron) it was important to use substances of high specific resistance. Carbon or platinoid being available, the latter was chosen on account of its low temperature coefficient. One form of resistance exhibited consisted of strips of thin sheet platinoid, about 6 metres long and 4 centimetres wide. Each was bent at the middle and doubled back on itself, thin silk being placed between the contiguous parts, and narrow ribbon used to bind the parts together. Twelve such strips arranged in series had a resistance of 2·95 ohms, and would carry a current of 15 amperes without changing its resistance more than $\frac{1}{10}$ per cent. This strip resistance was made by Messrs. C. A. Lamb and E. W. Smith, who, at that time (1888) were students in

Digitized by Google

the Central Institution, and to whom the author's best thanks are due for the praiseworthy manner in which they surmounted the difficulties which presented themselves. Another form of resistance, designed for portability, consisted of bare-wire spirals, each length having a left-handed spiral placed within a right-handed one of slightly larger diameter, and the two being connected in parallel. This device was found to reduce the inductance to $\frac{1}{10}$ or $\frac{1}{20}$ of that of a single spiral, accordiag as the diameters of the spirals approach towards equality. When the spirals are made of platinoid wire the ratio of inductance to resistance is very small, averaging about $\frac{1}{500000}$.

On "Pocket Electrometers,"

BY C. V. BOYS, F.R.S.

This communication described modifications of electrometers adapted for portability. As quartz fibres increase the delicacy and diminish the disturbing influences affecting instruments, much smaller controlling forces can be employed than when silk is used for suspensions. He had, he said, pointed out some time ago the great advantages arising from making galvanometers small. Applying similar reasoning to electrometers, he remarked that making an instrument one-tenth the size of an existing one reduced the moment of inertia of the needle to $\frac{1}{100}$, whilst the deflecting couple for given potentials would only be $\frac{1}{10}$ of its former value. The small instrument would, for the same periodic time, be 10,000 times more sensitive than the large one, provided the disturbing influences could be reduced in the same proportion. This, however, was not ordinarily possible, for any method of making contact with the needle such as by a fine wire dipping into acid or mercury prevented very small controlling forces being used. Still, by suitable devices, a large proportion of the full advantage could be obtained. A freely suspended needle without liquid contacts was essential to success. The first instrument described was one in which the needle was cylindrical (Fig. 1), contiguous quarters being insulated and connected to the opposite ends of a minute

FIG. 1.—Cylindrical "needle," with four insulated sections containing a dry pile.

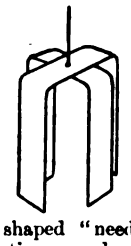

FIG. 2.—Cross shaped "needle," consisting of a strip of platinum and a strip of zinc, charged by its own contact difference.

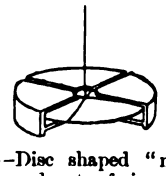

FIG. 3.—Disc shaped "needle," with alternate quadrants of zinc and platinum, one of the enclosing quadrants being removed.

dry pile placed within the needle; opposite quarters were then at the same potential, and at a different potential to the other pair of quarter cylinders. This was suspended within a glass tube silvered on the inside and divided into four parts by fine longitudinal lines. In such an instrument the needle and quadrants are reciprocal, and the deflection depends on the product of the difference of potential between the quadrants and that between the parts of the needle. Owing to the dry pile not being constant, the instrument was found unreliable, but when working at its best, a Grove cell would give 30 or 40 millimetres deflection. The next step was to make a cross shaped needle of zinc and platinum (Fig. 2), and rely on contact electricity to keep the parts of the needle at different potentials. This bold experiment proved remarkably successful, for the instrument was very sensitive. A disc-shaped needle, with quadrants alternately zinc and platinum, was then employed, and by this a small fraction of a volt could be measured. The weight of the disc was only $\frac{1}{20}$ of a gramme, and the instrument could be turned upside down or carried about in the pocket with impunity. Another small instrument with the quadrants of zinc and copper (Fig. 3) was exhibited, and by rotating them through an angle of 90deg., so as to bring them in a different position relative to the parts of the needle, a deflection of several degrees of arc was produced. In the course of his remarks, Mr. Boys made several suggestions relating to ballistic electrometers and electrostatic Siemens dynamometers, and pointed out the possibility of instruments such as he had exhibited being of use in elucidating the obscure points in connection with so-called "contact electricity."

The PRESIDENT complimented Mr. Boys on the beautifully simple and remarkably sensitive electrometers exhibited. He remembered that some years ago Mr. Gordon made a very small electrometer, but its insulation was insufficient for electrostatic work. He agreed with Mr. Boys as to the advantages of small instruments, providing sparking across or tilting of the needle could be prevented. On the other hand, he thought the use of small potential differences on the needle was a step in the wrong direction when great sensibility was required.

Prof. PERRY asked if the needle could not be kept charged by occasional contacts with a charged acid cup.

Mr. BOYS said he had originally intended using a fairly highly-charged needle, but had not yet done so. He also suggested that an electrometer of very small capacity might be made by reducing the quadrants surrounding a disc needle until they became like small tuning forks.

A Paper on "Electrification due to the Contact of Gases with Liquids," by Mr. J. Enright, B.Sc., and one on "The Expansion of Chlorine by Heat," by Dr. Arthur Richardson, was taken as read.

The following correction should be made in the report of the meeting on June 12th. For the first sentence in Mr. Blakesley's remarks on Dr. Lodge's experiments substitute:—"Mr. Blakesley asked whether the pitch of the resonant jars altered when the distance between the circuits was varied, for, according to theory, the mutual induction should diminish the self-induction, and cause the oscillations to be more rapid."

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 20, 1891.

More Litigation.—The past week has been a rather quiet one in electrical circles, except for wars and rumours of wars over infringing patents. In addition to the Edison lamp litigation, Brush storage battery suit, and the instituting of legal proceedings against the West End Railway Company for infringing the Sprague patents, two more new legal complications present themselves. Mr. J. C. Henry, one of the pioneers of electric traction in this country, has begun proceedings in the United States Court at Kansas City, Mo., against the Interstate Rapid Transit Company, using the Thomson-Houston system. This suit is brought under Henry's patent of a very early date. The points at issue relate to a cross-suspension or span wire system of holding the trolley wire, the under-running trolley, the arrangement of circuits in double multiple, insulated feeders, methods of curve construction, and form of trolley insulators. Besides Mr. Henry's suits, the Adams Electric Railway Company, of St. Louis, has begun proceedings under the old patent that showed an electric motor placed in the car-wheel and directly upon the axles. It seems probable, therefore, that the electric railway field is likely to be the arena of some lively litigation. It may be added that the Thomson-Houston Company and the Edison Company are also likely to be very soon involved in proceedings on the carbon brush patent, once owned by the Westinghouse Company, and sold, with the reservation of a licence.

The Electric Club.—The New York Electric Club was the scene of a very pleasant smoking concert last evening. One hundred and fifty members were present at the club-house, and the evening was a very enjoyable one, enlivened by music, recitations, interesting phonograph performances, and the like. The Electric Club is rapidly getting to be a central rendezvous for the best known electricians in the city, and their informal entertainments are widely appreciated.

Agitation Against the Trolley System.—The agitation over the introduction of the trolley system into Brooklyn still continues, and no decision has yet been reached. Somebody is very hard at work in spending a good deal of money in arousing popular indignation against the trolley. The outcome will very likely be a limited extension of the present trolley system on the outskirts of the city, but there is scarcely any doubt of the temporary success of the obstructive party.

Long Distance Telephone Lines.—A recent Paper by Mr. Gisborn, before the Royal Society of Canada, has again stirred up the question concerning the use of long distance telephone

Digitized by Google

lines. It has been an open secret for a good while that the wires of the long-distance companies have sometimes been used for purposes other than telephonic, and in Mr. Gisborn's description of rapid automatic transmitter work is a very broad hint as to what lines were used in the experiments, and it would be an interesting question to determine how far these experiments have run into commercial work. It has been rumoured more than once that the Western Union is likely to bring suit under the contract that prohibits tne use of telephone lines for telegraphic work. A few trunk lines with automatic transmitters would be a pretty formidable factor in the transmission of messages between large centres of population, and we may be treated to an interesting revelation as to what can be, and, perhaps, has been done. The Western Union Telegraph Company is not at all likely to sit quietly in the presence of an active competitor, and, on the other hand, the telephone companies, in view of the approaching expiration of the patents, would not be at all averse to having an extensive and lucrative business to fall back upon.

CORRESPONDENCE.

THE CHEMISTRY OF THE SECONDARY CELL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 26th June I am glad to see Mr. Hibbert has called attention to a passage in my article on the Chemistry of the Secondary Cell which might mislead those unacquainted with the work of Dr. Gladstone and himself. I had no intention of implying that the analytical method was employed both in the course of the work on litharge and minium, but meant that reviewing their work on the formation of an oxysulphate in the cell as a whole the non-formation was not absolutely proved, because it was just possible the method employed in part of their work might have destroyed the oxysulphate.

As analysis was not made use of in the work on litharge it did not occur to me that my remark could be taken as applying to that Paper; however, I am much obliged to Mr. Hibbert for explaining a passage which is ambiguous.

Hoping you will be able to find space for the above explanation.—Yours, &c., G. H. ROBERTSON.

30, Hemstall-road, West Hampstead, N.W.,
June 27, 1891.

MAGNETIC SEPARATOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice in your commentary on the electrical apparatus at the Royal Agricultural Show, that you do not notice the magnetic separator shown by the Hardy Patent Pick Company, of Sheffield, and made under the patents of Mr. Elliot, myself, and Mr. C. W. Atkinson, and manufactured by Messrs. W. T. Goolden and Co. This is the more curious as the separator was by no means a small machine, being nearly 5ft. in diameter, and weighing probably, with the timber work on which it was mounted, over a ton.

As this is the first time this machine has been publicly exhibited, and as we believe it is an important improvement on any magnetic separator previously used for this purpose, we should be glad if you would note this correction. I may also add that a magnetic separator of a different class was exhibited by Messrs. Harrison Carter and Co.—I am, Sir, &c.,

LLEWELLYN B. ATKINSON.

Woodfield Works, Harrow-road, London, W.,
June 29th, 1891.

THE CAUSTIC SODA AND CHLORINE SYNDICATE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Our attention has been called to an article in your issue of the 19th ult., on the Electrolytic Production of Caustic Soda and Chlorine. The article is a model of fair criticism, and we have no wish to minimise the force of the considerations advanced by the writer. We would ask, however, your permission to add the following few particulars in explanation of the "report" (prepared for submitting to a non-technical directorate), for which we are gently taken to task. The back E.M.F. of the ions separated under the conditions of the Greenwood cell is about 2·5 volts.; the current density under the conditions of our experiments was about 2 amperes per square decimetre of sectional area of diaphragm. From these data it is easy to estimate the factors of the aggregate fall of potential, amounting to from 4·5 to 5 volts between the terminals, and to see that the resistance introduced by the diaphragm is satisfactorily low.

The electrolysis being unattended by secondary reactions between the ions—as was shown by the absence of chlor-oxygen compounds in the solution of the cathode compartment—there would be no reason for any sensible divergence of the results obtainable in the large and small scale. Mr. Greenwood's claim for a 70 per cent. (ampere) efficiency we confirmed on the small scale, and are satisfied can be realised on the working scale.

The important points to be solved are as you indicate, the life of the anodes and of the diaphragms, that is the costs of maintenance. The recognition of this was the basis of our recommendation to try the system on the scale of a 40-H.P. installation.

We cannot trespass on your space, nor is the opportunity a favourable one, to enter upon a thorough technical discussion of the prospects of the application of current energy to this department of chemical production. The Hermite process, to which you have also alluded in your article, has made considerable headway in France, and we hope to have the opportunity of including an account of the results of running the several installations in the general survey which we intend to prepare for the technical public.—We are, Sir, &c.,

4, New Court, W.C., July 1, 1891. CROSS and BEVAN.

LEGAL INTELLIGENCE.

United Telephone Company v. Ladd and Co.

This was an action in which the plaintiff Company, of Oxford-court, Cannon-street, sought to recover against the defendants, 116, Queen Victoria-street, the sum of £20 and interest as the rental of a telephone used by them. Mr. Payne was counsel for the plaintiff Company, and Mr. D'Eyncourt appeared for the defendants. Mr. Payne said the agreement which was entered into by the defendants made them liable to pay the amount claimed. The defendants undertook to pay the amount in advance, and if they desired to put an end to the agreement, three months' notice had to be given, expiring on October 1st. No verbal notice could be recognised. In September last year the plaintiffs wrote to the defendants applying for the rent due, and in reply they received a letter saying they wished no longer to continue the use of the telephone. They refused to pay the rent, saying the telephone had been out of repair, and endeavoured to repudiate payment in that way. The defendants had set up a counter-claim for damages, but as it was out of time it could not be entertained. Mr. D'Eyncourt said the plaintiff Company agreed to keep the telephonic apparatus in working order. This had not been done, and the telephone was quite useless to the defendants during the latter part of the time for which the plaintiffs had been paid. They found it easier to send a messenger with a letter rather than use the telephone. They had paid since October, 1885, till last October, and during the last year it was continually becoming out of order. The defendants often tried to use it, but could not get attended to. On one occasion the bell kept ringing for a long time, and at other times the defendants were cut off in the middle of a conversation. Once, when the defendants tried to communicate with another subscriber, they heard a voice in the plaintiffs' office saying, "Oh, it's too late; tell them they are engaged."

The learned Commissioner said all of this was the subject of the counter-claim, and as the counter-claim was out of time, he must find for the plaintiffs on the claim, with costs.

BOOKS, &c., RECEIVED.

"An Introduction to the Mathematical Theory of Electricity and Magnetism." By W. T. A. Emtage, M.A. (Oxford: Clarendon Press.)

"A Manual of Practical Electro-Therapeutics." By Arthur Harries, M.D., and H. Newman Lawrence. (The Nursing Record Series, No. 3.) (London: Sampson Low, Marston and Co.)

"Vorlesungen über Maxwell's Theorie der Elektricität und des Zichtes." Part I. Von Dr. Ludwig Boltzmann. (Leipsig: J. A. Barth).

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

TELEPHONE PATENTS.—Our readers will find in our advertisement columns a notice from the Directors of the National Telephone Company (Limited) calling attention to the fact that it is only the first of Edison's transmitter patents which expires on the 30th inst., and warning the public against the manufacture, sale, or use of the various forms of carbon transmitters in common use in this country, the patents for which do not expire until the latter part of 1892 and the beginning of 1893.

MESSRS. GILBERT AND CO.—This firm have secured the contract for lighting Messrs. Hopkins' Market at Cardiff.

THE LEEDS ASSOCIATION OF ENGINEERS.—This association has more recently taken commodious rooms at 5, Park-lane, Leeds. Mr. J. A. Tempest is the honorary secretary.

MESSRS. WOODHOUSE AND RAWSON UNITED (LIMITED).—We are notified that Mr. Charles A. Smith, of the Athenæum, 71, Temple-row, Birmingham, has been appointed agent for Birmingham and district of the above firm. Mr. Smith has opened show rooms at the above address, where samples of Messrs. Woodhouse and Rawson's manufactures may be seen, and where local orders will be executed from stock.

THE WEYMERSCH BATTERY.—We have received from the Weymersch Battery Company some illustrated particulars announcing, among other matters relating to the battery, that it can be seen in action every day at the offices of the Company, where it is employed in working one of the Blackman Ventilating Company's fans, as well as a complete electric lighting installation.

THE DODGE PATENT WOOD SPLIT PULLEYS.—We have received from Mr. Charles H. Ewen illustrated particulars of these split pulleys. Many advantages are claimed over those generally in use. It is claimed they are 40 per cent. lighter than wrought iron or steel pulleys, and that they give from 25 to 60 per cent. more power with the same belt and tension. The printed particulars also give prices and some testimonials.

FIRES.—We regret to announce that the business premises of Mr. Zimdars, of Gray's Inn-road, W.C., were burnt out a few days ago, Mr. Zimdars being absent at the time, we understand, on the Continent.——On Wednesday the principal portion of the Phœnix Chemical Works at Maryhill, near Glasgow, belonging to the Paterson Chemical Manufacturing Company, was destroyed by fire, and damage estimated at £8,000 was done.

DISSOLUTIONS OF PARTNERSHIP.—Floyd and Stanley, electrical engineers, 2, Victoria Mansions, Victoria-street, London, S.W.; Saunders, Greaves, and Saunders, trading as W. and J. Saunders, electrical appliance manufacturers, 3, Augusta-street, Birmingham.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

May 28, 1891.

9,048. F. COGAN, T. WRIGHT, and R. COLLINS. London. The lighting by electricity of all vehicles drawn by horses, mules, and other animals.

9,073. J. F. MUNSIE. London. Improvements in electric railways.

9,079. C. HOEPFNER. London. Improvements relating to the electrolytic extraction of metals, and to the electrolysis of other substances.

May 29, 1891.

9,103. J. SWINBURNE. Teddington. Improvements in dynamo-electric machines and motors.

9,104. E. W. HARVEY and C. W. ALLDRED. London. Improvements in the manufacture of electric light carbons.

9,107. G. H. BARNES. Birmingham. A connecting union for electric light fittings.

9,145. H. C. L. HOLDEN, B. M. DRAKE, and J. M. GORHAM. Erith. Improvements in electrical measuring instruments.

June 1, 1891.

9,135. T. H. COURTENAY. London. Means for preventing the interference of induction currents of the earth and line wires in telephonic and other electric circuits.

9,190. S. J. DAVIES. London. An improved electric clock.

9,229. SIEMENS BROS. and Co. (LIMITED). London. Improvements in telephones. (Siemens and Halske, Germany)

9,241. W. P. THOMPSON. Liverpool. Improvements in or appertaining to electric railways. (C. K. Harding, United States).

9,245. A. LINHART and C. SEITZ. Liverpool. Improvements in telegraphic apparatus.

9,249. F. J. ROWAN and W. MCWHIRTER. Glasgow. Improvements in electro-magnets for holding tools, lamps, brackets, or other articles, and for telegraphic and other apparatus.

June 2, 1891.

9,291. A. E. BISHOP. London. Improvements in electric arc lamps.

9,299. W. R. SYKES, senior. London. Improvements in apparatus for electrically controlling and registering the movements of keys in connection with railway block instruments, and for other purposes.

COMPANIES' MEETINGS.

West African Telegraph Company (Limited).

The sixth ordinary general meeting of the Company was held at Winchester House yesterday (Thursday), Sir John Pender in the chair.

The SECRETARY (Mr. William Payton) having read the notice convening the meeting, and the minutes of the last meeting having been read and signed,

The CHAIRMAN said: Gentlemen, you have had the report in your hands some days, and I presume you will take it as read. If so, I shall, as usual, make a few remarks before I ask you to pass the resolution. Our revenue for the year 1890 amounted to £68,377, as against the takings for 1889 of £64,661, showing an increase of £3,716. There has been a growth of traffic throughout the whole line, but the Company's revenue does not expand in the same ratio as the traffic, for the following reasons:—Our receipts from telegrams sent from Portuguese stations are guaranteed by the Government to the extent of £41,900. Our accounts with Portugal for 1890 show that we had to claim only £29,455, and judging from the traffic now passing we shall probably have to claim even less than this sum for the current year. This increase of traffic of course places us in a sounder financial position without, however, increasing our available revenue, the traffic increase coming under the guarantee. With respect to the French stations, the case is different. At these all the money taken is in addition to the subsidies received from the French Government—viz., £12,000 per annum. We also benefit

Digitized by Google

by having a share in the revenue derived from telegrams exchanged with the Cape Colony, Orange Free State, Natal, and the Transvaal. Having a joint purse with the Eastern and other companies interested in this traffic, we can always rely on a certain income, even should our cables be interrupted for a time, and in the growth of traffic in this direction we shall participate. The total working expenses for 1890 amounted to £21,685, against £21,155 in 1889, or an increase of £530. Several of the items show decreases and others increases, the principal increase being under the head of working expenses at stations, which this year amounts to £16,511, against £15,666 in 1889—an increase of £845. To add to the comfort of our staff, we have improved the houses at Conakry, Kotonou, and Gaboon by fitting new improved jalousies, and have also considered it necessary to supply those and some other stations with additional furniture, the total cost of which has been charged to revenue. We make a point of keeping our young men as comfortable as possible, and giving them good homes, because unless we do we cannot expect an efficient service. It is always an important consideration that we have an efficient staff, and they are made efficient through our taking great care of them. We have also a full year's working under the agreement with the African Direct Company of the joint stations Bonny and Sierra Leone, against only eight months and six months respectively in the corresponding period. The repairs to cables during 1890 cost £4,788, against £1,780 in the preceding year, or an increase of £3,008. As will be seen from the accounts, the repairs to the Bolama-Bissao cable cost £2.092, and, as explained in the report, we have considered it expedient to pay the sum of £2,500 per annum for the call of a repairing ship when occasion rises. Although the arrangement, so long as the agreement lasts, will cost us £2,500 per annum, it will be found more economical in the end, and our repairs will be done more expeditiously. We are only charged during service on repairs from the time the ship leaves her station abroad, instead of with the expenses of sending the ship from London. It is in contemplation to have the ship specially fitted for this particular service, and to have it nearest places where work will occur. I do not suppose that the cost of the ship, being divided amongst the different companies, would add much to the sum we are paying for the ship. However, that is a question for the experts, Sir James Anderson and others, to decide. We are looking after a ship, but we have not decided upon anything yet. In this year's accounts is included the full annual charge against revenue for interest on and redemption of Five per Cent. Debentures £23,693, against £17,643 for 1889, an increase of £6,050. The annual charge against revenue in future, until all the debentures are paid off, will be the same as appears in this year's accounts. They will all be paid off in 18 years' time. It is proposed to pay a final dividend of 3 per cent., which makes, with the previous interim dividend at the rate of 2 per cent., a total distribution of 5 per cent. for the year, and the balance of £6,015 has been added to the general reserve fund, which, with the interest received on investments to date, now amounts to £26,427. I think, gentlemen, you will agree with me that this is a very satisfactory state of things, maintaining a steady dividend and largely increasing our reserve fund, and it will be the policy of the Board to largely increase our reserve fund, and maintain a steady and substantial dividend. Now, gentlemen, I have given you the hard facts connected with the last year's work, and I will give you now a little bit of the sentiment which always is associated more or less with telegraph enterprise. I think during the last two or three years I have led you on from one step to another, showing that there has been a considerable progress. We have risen from no dividend to a 5 per cent. dividend, which I have referred to more than once, and I have also referred to the great development which must go on in this great continent of Africa. We have met with competition on the part of the Germans, on the part of the French, and on the part of the English. The Portuguese also are showing more energy, but Portugal has been very long associated with Africa, and she has not brought about that development which we would naturally have expected. At the same time our relations with Portugal have been very highly satisfactory. They have paid our subsidies in a very straightforward way, and altogether we have no reason to complain. However, I think it would be to the interests of Portugal, and to the interests of progress, if they were just to part with certain places in which they really cannot make money, but which must cost a good deal. By the sale of these places they would be in a much more comfortable position at home. I believe it would be better for all parties concerned, and I do not think it would rob Portugal of the slightest degree of prestige among the nations. We know exactly the position of Portugal, and she would become richer if she was to pursue the policy suggested. The other countries that are interested in the development of Africa are showing considerable energy, and I am pleased to hear that with Germany we are acting in a very harmonious way, and, therefore, I see large results in that direction. France is also doing a great deal, and though she, perhaps, has a greater idea of her power than other nations, still she has enterprise and energy, and I think benefit will accrue from that energy. We have just sent, or rather there has gone out, one of our distinguished statesmen; he is going to look round, and his observations and influence may stimulate things. We know that the South African Company is one in which there are men of great position and great enterprise. For instance, the Premier of South Africa, Mr. Rhodes, is a man of great energy, and if anything is to be done in Africa he and his friends will do it. I mention these facts simply to lead you to this, that we are ahead of everything. We are there to meet their requirements, and I think if they benefit Africa they must benefit us, and, therefore, I look forward to the future of this Company with very considerable interest and with very great satisfaction. With these remarks I beg to move the first resolution:—

"*That the report and accounts for the year ended December* 31, 1890, *submitted to this meeting be, and they are hereby, received and adopted, and that a dividend be declared payable on and after this date of 6s. per share free of income-tax, making, with the dividend already paid, a total distribution for the year of* 5 *per cent.*"

This was seconded by Sir H. MANCE, and carried unanimously.

It was then proposed by the CHAIRMAN, seconded by Sir JAMES ANDERSON, and carried unanimously:—

"*That Sir Henry C. Mance, C.I.E., and John Denison Pender, Esq., be, and they are hereby, re-elected Directors of the Company.*"

Mr. WELLS then proposed, and Mr. EAST seconded, and it was carried unanimously:—

"*That Messrs. Deloitte, Dever, Griffiths, and Co. be, and they are hereby, re-elected auditors of the Company.*"

Mr. OWEN proposed a vote of thanks to the Chairman and Directors, which was seconded by Mr. JOSEPH T. EAST, and carried unanimously.

The CHAIRMAN: I am sure my colleagues agree with me in thanking you for the acknowledgment of our services. We always feel that the more we can make things satisfactory to the shareholders the more we strengthen our position.

The proceedings then terminated.

City and South London Railway Company (Limited).

An adjourned extraordinary general meeting of this Company was held, on Tuesday last, at Winchester House, Old Broad-street, E.C., Mr. C. Grey Mott presiding.

The CHAIRMAN said: Gentlemen, you will recollect that at the meeting of which this is an adjournment it was agreed that in the interval the Directors should have a conference with some of the larger shareholders of the Company, to see if there were any method that could be devised for raising the additional capital in a better and more economical way than that which had been proposed to you by the Directors. That conference has been held, the matter has been very fully and carefully discussed, and in the result it is agreed by all parties that the recommendation of the Directors made to you is the best and the most economical way of raising the money. It is proposed to slightly modify the resolution, which quite meets with the views of the Directors themselves. Although we create £150,000 of preference shares, it is now proposed that we should be authorised to issue only £50,000. If more money is required, a fresh vote of the shareholders will be asked. It has also been thought desirable that the preference shares should carry with them the ordinary voting power—that is, the same as the ordinary shares have. I therefore propose the first resolution, as follows:—

"*That the resolution passed at the general meeting of the Company, held on the* 12*th of August,* 1890, *relating to the creation of the new capital authorised by the City and South London Railway Act,* 1890, *be, and the same is hereby, cancelled and annulled, except as to the creation or issue of* 5,000 *ordinary shares of* £10 *each, part of the total number of* 20,000 *shares authorised by the said resolution.*"

Mr. HANBURY seconded the resolution, which was carried unanimously.

The CHAIRMAN: The second resolution is:—

"*That* £150,000 *of the share capital, being the balance of the* £200,000 *authorised to be created by the City and South London Railway Act,* 1890, *be, and the same is hereby, created, in* 15,000 *preference shares of* £10 *each, bearing interest at the rate of* £5 *per cent. per annum, and that the Directors be, and they are hereby, authorised to issue* 5,000 *of such preference shares, in such amounts, at such times, and on such terms and conditions, as they may deem fit; the holders of the preference shares hereby created shall be entitled to vote on the same scale of voting as the holders of ordinary shares.*"

Mr. HANBURY seconded the resolution, which was carried unanimously.

The CHAIRMAN, in reply to a question, said that under the Companies Act the shares could not be made cumulative.

The proceedings then terminated.

National Telephone Company (Limited).

The following is the report of the Directors for the year ending 30th April, 1891, to be presented to the shareholders at the eleventh ordinary general meeting of the Company, to be held at the City Terminus Hotel, Cannon Street, London, on Thursday, the 9th July, 1891, at twelve o'clock noon:—

The Directors have the pleasure of submitting to the shareholders the accounts for the year ended 30th April, 1891, showing a balance to the credit of net revenue account of £194,821. 8s. 1d. after providing among other charges for the expenses of issuing the new Debenture Stock, and the accrued interest thereon to 30th April, 1891. Of this amount the sum of £62,973 has been absorbed by the payment of an interim dividend on the preference shares at the rate of 6 per cent. per annum, and on the ordinary shares at the rate of 5 per cent. per annum for the first six months of the year. The Directors propose to pay a further dividend on the preference shares at the rate of 6 per cent. per annum, and on the ordinary shares at the rate of 7 per cent. per annum for the last half of the year, which will absorb a further sum of £86,365. 19s., leaving a balance of £45,482. 9s. 1d. Out of this amount they propose, under Article 113 of the Articles of Association, to transfer to reserve account £40,000, bringing up the amount of the reserve fund to £93,500. There will then remain £5,482. 9s. 1d. to be carried forward to next year.

The extension of the Company's business during the last year has been so large, that notwithstanding the heavy reduction of rates which the

Digitized by Google

Directors thought it wise to make in the provinces, in view of the expiration of some of the Company's most important patents, the gross revenue, which last year stood at £411,114. 14s. 1d., reached £418,560. 7s. 8d. on the 30th April, 1891, and is still steadily increasing.

The number of exchange and private line subscribers over the whole of the Company's system, excluding the South of England district, which last year was 29,257, was on the 30th April, 1891, 35,440, an increase of 6,183 subscribers during the year, and the number of subscribers is still increasing. The Directors are still acting upon the conviction that it is of vital importance to continue the policy of developing and improving the Company's system, and of giving greater facilities to the public.

The accrued rental for the year ended April 30, 1890, was £364,704. 17s. 5d. For the present year it is £422,378. 6s. 2d. The working expenses for the year ended April 30, 1890, amounted to £148,457. 0s. 9d., being 40·7 per cent. on the accrued rental, whilst the working expenses of this year amount to £184,056. 9s. 6d., being at the rate of 43·5 per cent. on the accrued rental.

The Directors have taken over the business of the South of England Telephone Company, Limited, which is now merged in this Company.

On the amalgamation, in July, 1889, of the three principal companies, it was thought desirable that the customary annual retirement of one-third of the Directors should not take place at the end of the first year, in order that the numerous arrangements rendered necessary by the amalgamation and reorganisation of the Company might not be interfered with. These having been now completed, and two of the provincial companies, the Northern and South of England Telephone Companies, having been absorbed, the Directors think they ought all, at this meeting, to place their offices at the disposal of the shareholders, and submit themselves for their approval. They, therefore, now all retire, and being eligible, offer themselves for re-election.

The auditors, Messrs. Welton, Jones, and Co., retire, and are eligible for re-election.

NEW COMPANIES REGISTERED.

BABCOCK AND WILCOX (LIMITED).—Registered by Hollams, Sons, Coward, and Hawksley, Mincing-lane, E.C., with a capital of £240,000, in 10,000 preference shares of £10 each, and 14,000 ordinary shares of £10 each. Object: to acquire the undertaking heretofore carried on in London, Glasgow, and elsewhere, other than in the United States of America and the Island of Cuba, by the Babcock and Wilcox Company of New York, in accordance with an agreement expressed to be made between the Babcock and Wilcox Company of New York, of the one part and the Company of the other part, and to carry on business as manufacturers of water-tube steam boilers, and generally the business of engineers and manufacturers of machinery of every description.

GLOUCESTER ELECTRICITY SUPPLY COMPANY (LIMITED).—Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £100 in £1 shares. Object: to carry on business as electrical engineers, electricians, &c. Most of the regulations of Table A apply.

MIDDLESBOROUGH ELECTRICITY SUPPLY COMPANY (LIMITED).—Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £100 in £1 shares. Object: to carry on generally the business of electrical and mechanical engineers, &c. The regulations contained in Table A mainly apply.

QUEEN ANNE'S MANSIONS LIGHTING AND HEATING COMPANY (LIMITED).—Registered by Paine, Son, and Pollock, 14, St. Helens-place, E.C., with a capital of £60,000, in £10 shares. Object: to adopt and carry into effect an agreement expressed to be made between William Robert Renshaw of the one part, and this Company of the other part, and to carry on, in the city of Westminster and elsewhere (and in particular at Queen Anne's Mansions, Westminster), the business of an electric and gas lighting, heating, and power company in all its branches.

ROCHDALE ELECTRICITY SUPPLY COMPANY (LIMITED).—Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £100 in £1 shares. The objects of this Company are sufficiently indicated by the title. With slight modifications, the regulations contained in Table A apply.

STOKE-ON-TRENT ELECTRICITY SUPPLY COMPANY (LIMITED).—Registered by Sydney Morse, 4, Fenchurch-avenue, E C., with a capital of £100 in £1 shares. Object: to carry on the business of an electrical engineer in all its branches. Most of the regulations contained in Table A apply.

WYLIE, BROWN, AND CO. (LIMITED).—Registered in Scotland, by Mr. Thomas Neilson, solicitor, Glasgow; capital, £1,000 in £1 shares. Object: to take over from the trustee of the sequestrated estate of Wylie, Brown, and Co., West-street, Tradeston, Glasgow, the goodwill of the business, the whole of the plant, stock-in-trade, outstanding accounts, remainder of the lease, and all assets of that firm, and to carry on the business of iron, brass, and steel founders, and general founders and engineers, in continuation or extension of the business hitherto carried on by that firm.

CITY NOTES, &c.

BOURNEMOUTH AND DISTRICT ELECTRIC SUPPLY COMPANY (LIMITED).—A prospectus of this Company has been issued by the Electric and General Investment Company (Limited), inviting subscriptions for 6,000 shares of £5 each, payable 10s. per share on application, 10s. on allotment, £1 on August 1 next, £1 on September 1st next, and the balance in calls not exceeding £1 at intervals of not less than three months. The Company is formed to undertake the supply of electric light and power in Bournemouth, and to take over the existing central station, business, and undertaking under the Provisional Orders now being worked by the Brush Electrical Engineering Company in Bournemouth. A map is issued with the prospectus showing the area supplied by the undertaking, and the Bournemouth Company takes over the existing plant, erections, and goodwill and interest of the Brush Company. The station, plant, and circuits have been inspected by Prof. J. A. Fleming, whose report is appended to the prospectus. The managing director of the Company is Mr. H. W. Wollaston, the secretary is Mr. Charles Offer, and the offices are Observer-chambers, Albert-road, Bournemouth. The lists opened on Monday and closed yesterday for both town and country.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the past week amounted to £5,653.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The traffic receipts of this Company for the past week amounted to £697. The aggregate receipts for the half-year to date are £19.197. Mr. H. H. M. Smith has resigned the position of secretary to this Company, and has been succeeded by Mr. W. F. Knight.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of June were £3,500, as compared with £3,324 in the corresponding month of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The Company announce that, subject to final audit, the accounts show, after placing about £95,000 to reserve fund, a balance available sufficient to pay at the general meeting, on 16th July inst., the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum on the preference shares, less income tax; and a final payment of 2s. 6d. per share, with a bonus of 3s. per share, both free of income tax, on the ordinary shares, making with previous payments on account, a total distribution of 6½ per cent. on those shares for the year ended 31st March, 1891. The transfer books of the Company will be closed from the 9th to 16th July, both days inclusive.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—This Company has declared an interim dividend for the quarter ended March 31st last of 2s. 6d. per share, payable on the 15th instant.

HALIFAX AND BERMUDAS CABLE COMPANY (LIMITED).—The coupons of this Company's Four and a-Half per Cent. First Mortgage Debentures, due June 30, 1891, will be paid on and after that date by Messrs. Prescott, Dimsdale, and Co. (Limited), 62, Threadneedle-street, E.C.

QUEEN ANNE'S MANSIONS LIGHTING AND HEATING COMPANY (LIMITED).—The prospectus of this Company has been issued this week by the Electric and General Investment Company, in conjunction with the Gas, Water, and General Investment Trust (Limited). The present issue is for 430 Six per Cent. First Mortgage Debentures of £100 each. The Company is formed with a capital of £60,000, divided into 3,000 Four and a-Half per Cent. Cumulative Preference Shares of £10 each, and 3,000 ordinary shares of £10 each. These shares are, however, not for subscription. The debentures are payable as follows:—£35 per cent. on application, £35 per cent. on allotment, and £30 per cent. on September 1st next. The consulting engineer to the Company is Mr. J. S. Raworth, M.I.E.E.; the secretary is Mr. J. A. Kelman. The Company is formed for the purpose of taking over and working the contract for the heating and the supply of electric light and hydraulic power to the large block of buildings known as Queen Anne's Mansions. Accompanying the prospectus is a report from Mr. Raworth. The lists closed yesterday (Thursday) at four o'clock. The prospectus stated that the figures upon which the estimated profits are calculated "do not include any profit to be derived from the supply of electric light and power to any other buildings and places in the same neighbourhood, which it is believed can be undertaken by the Company with good results." In reference to this clause, Mr. Bax, the manager of the Westminster Electric Supply Corporation, wrote to the *Financial News* of Wednesday as follows:—"It is but right that the public should be made aware that Parliamentary powers for the supply of electricity in the district in which Queen Anne's Mansions are situated have as yet only been granted to one supply company, viz., the London Electric Supply Corporation (Limited), and that, as similar powers are this session being conferred upon the Westminster Electric Supply Corporation (Limited), there is no probability of the Queen Anne's Mansions Lighting and Heating Company being authorised to supply electric light and power beyond the area covered by the mansions themselves." To this Mr. Kelman replied, in the next issue of our contemporary, that his company had "a large present and profitable revenue quite independent of Parliamentary powers, something a little more substantial than 'similar powers being conferred' for the supply of electricity."

ST. JAMES AND PALL MALL ELECTRIC LIGHTING COMPANY (LIMITED).—The Directors have declared an interim dividend at the rate of 7 per cent. per annum for the half-year ending June 30th, payable in the first week of July. The transfer books will be closed from the 1st to 10th July, both inclusive.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The following are the traffic receipts of this Company for the past four months:—March, £3,250; April, £600; May, £1,275; June, £1,575. The southern cables are still interrupted owing to the revolution in Chili.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended June 26, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brasilian Telegraph Company (Limited), were £3,833.

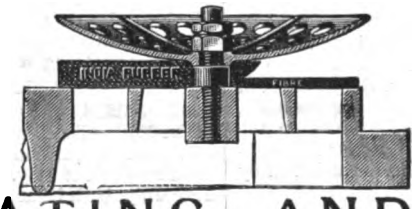
NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 686.—Vol. XXVII. FRIDAY, JULY 10, 1891. Price Fourpence.

NOTES.

The Incorporated Association of Municipal and County Engineers have plenty of food for study in the two Papers which have been read to them by Mr. Preece and by Prof. H. Robinson. Both of these require a little digestion, and if Mr. Preece provided a more palatable discourse, Prof. Robinson perhaps offered more nourishment. Mr. Preece was in a rather optimistic mood, and argued that because a unit of electrical energy can be produced for industrial purposes for one-third of a penny "it is equivalent to gas produced at threepence per thousand feet," and that this "shows what a vast field of development is before electric light." He points out that the load factor—that is to say, the variable and brief supply during the day accounts for much, but in his recent Paper on Mains (*The Electrician*, May 29, p. 109) he gave a more important reason for the difference between this figure and the usual selling price. "If we can reduce the cost of distribution and its up-keep by 50 per cent., we should be able to supply light by electrical energy more cheaply than by gas." The one-third of a penny would sometimes purchase a hundredweight of fresh herrings, but not for delivery at one's door in London. The load factor difficulty might be overcome by the use of batteries, if these could be made to redeem the promises made for them by their inventors and manufacturers.

Mr. Preece has been somewhat criticised in the gas journals, as might be expected, for giving the low figure of 10 candles as the light of "an ordinary burner, supposed to be consuming 5ft. per hour," and the Paper of Prof. H. Robinson, of which an abstract will be found in another column, contains figures relating to large and improved burners, in which "flat flames in clusters" are said to yield as much as five candles per cubic foot per hour. But, so far from admitting that these figures disprove those of Mr. Preece, we would point out that hundreds of miles of streets are lit with these miserable flickering jets, and that it is the competition of electric light which is inducing the gas engineers to arouse themselves, and to provide here and there a few more efficient burners. When the 10-candle burner becomes the exception rather than the rule, the public will have to thank electric lighting for the change.

It is very satisfactory to find in Prof. H. Robinson's Paper that some attention is paid to the matter of illumination, which is the ultimate object of electric light, but which receives very little attention from engineers. The author speaks of the angle at which the light falls as the angle between the ray and the horizon; but, in optical science, the angle of incidence is always taken as the angle between the ray and the perpendicular to the surface. Thus, the ray striking the ground below the lamp is said to have no inclination, or an angle of incidence of 0. The illumination of a surface is proportional to the cosine of this angle of incidence, and if we accept the author's mode of reckoning it would be proportional to the sine of his angle. But he says, "the light falling on a unit area of pavement varies inversely as the square of the distance from the lamp, and is directly proportional to the angle at which it falls," and he goes on to remark that "this angle is nearly proportional to the height of the lamp divided by the distance." It is not clear whether this means the horizontal or the slant distance from the lamp. The latter is correct.

In giving the candle-power of arc lamps at different angles, Prof. H. Robinson speaks of the candle-power at an angle of 20deg. (from the horizontal) as representing a fair average of the power from arc lamps. This is, doubtless, true, but not very clear; for it suggests that the ray falling at this angle gives an illumination on the pavement which is the average of the surrounding illumination. This is far from the case; for, owing to the distance from the lamp and the inclination of the ray, the illumination would be only ·04 of the maximum; that is, of a vertical ray. We hope that Prof. Robinson will give further attention to this important subject, and put into practice at St. Pancras some of the very practical suggestions contained in his Paper.

The progress of electric traction in this country is slow but sure. So slow that the Cantor lectures delivered by Mr. Kapp in February last have not become stale on account of recent developments; and so sure is it that at the recent meeting of the Tramways Institute the general feeling of the meeting and the opinion of the chairman were strongly in favour of the use of the electric motor. The Cantor lectures, which, according to our custom, we reproduce in full, deal very carefully with electric traction, and little, if any, new information as to actual cost of working in this country have been published since these lectures were given. We neglect American figures because the conditions are so different that it is impossible to accept them as a guide. Our readers will remember that in February last we commented on some figures which were then given by

Digitized by Google

Mr. KAPP, relating to the Barking Road line, and that the Company who are now working these cars strongly objected to the conclusions which were drawn from them. Mr. KAPP, forgetting or being unaware that his informant had been connected with, and had derived his data from, the working of another traction company, withdrew the obnoxious figures, but we regret that no authorised statistics have been given in their place. We shall reprint this part of the Cantor lecture next week, and should be glad to append the authentic figures. The future development of electric traction is largely a question of operating expenses per car mile, but it appears that the receipts of the three miles at Birmingham, on the Bristol road, show that the electrical cars are more popular than the horse cars, as is indicated by the takings of 9·29d. per mile by the latter, against 14·26d. per mile by the former. Thus we may expect that even while electric traction costs more than horse traction, it may compete with it on account of greater comfort and convenience, just as electric light successfully competes with gas for these reasons.

IN a recent number of the *Comptes Rendus*, Mr. MICULESCO describes a new determination of the mechanical equivalent of heat, by a method essentially the same as that originally used by JOULE, but embodying several improvements in detail. The power used in turning the paddles was measured more directly at the place of application. It was supplied electrically by a motor supported at the middle of the beam of a balance, and the moment exerted in turning the paddles could be measured by adjusting the weights in the scale pans. This moment, when multiplied by the revolutions of the motor, gives the power expended in churning up the liquid, independently of any friction taking place in the motor itself; while in the analogous experiment of JOULE the friction of the cord and pulleys produces a slight error in the estimate of the power. Another improvement consisted in the exertion of much greater power than in JOULE's measurements. The electric motor was of the Gramme type, having an output of 1 H.P., so that heat was quickly generated. Errors due to radiation were eliminated by working between temperatures but very slightly different from that of the surrounding atmosphere, while errors caused by uncertainty about the water equivalent of the apparatus were altogether avoided by adjusting the flow of water into, and out of, the calorimeter till the temperatures of the influx and efflux were constant. The difference of temperatures was read with great accuracy by means of a thermo-electric couple, previously calibrated against a standard thermometer. The value, 426·7, found for the mechanical equivalent of heat, is exceedingly close to JOULE's number, which, when reduced to correspond with the air thermometer at Paris, is 426·5. The value, 772, is, perhaps, more familiar to our readers as the number of foot-pounds required to heat one pound of water 1°F. The new determination in such units would be 772·3. It may be remembered that Messrs. COOPER and ANDERSON conducted some experiments on a large scale in 1887, and arrived at the value 769, but it is not at all clear that their method was free from essential errors in the arrangement of the apparatus, or from errors due to radiation and conduction. Prof. MARKS, in 1885, obtained the number 772·8 by experiments made with the "Tatham Dynamometer." Perhaps the chief interest of the results of MICULESCO and MARKS is their proof of the extraordinary accuracy with which JOULE worked.

IN our obituary notice of Prof. WEBER, the word "re-invented" was used in connection with Sir WILLIAM THOMSON's application of the mirror for indicating the deflections of a galvanometer. There was no re-invention. GAUSS and WEBER employed mirrors weighing several ounces in their magnetometer work, but their arrangement was suitable only for showing very slow changes. HELMHOLTZ reduced the weight of the mirror to about an ounce; and, in a Paper communicated to the Royal Society about 1855, and republished in Vol. II. of his collected Papers, Sir WILLIAM THOMSON refers to HELMHOLTZ's instrument as his starting point. This was still much too heavy for submarine telegraphy; and no instrument was in existence which would give a continuous indication of the change in direction of the small currents which constitute cable signalling, and which was capable of following their variations continuously, until a reflecting galvanometer was provided having a mirror and attached needle, weighing only half a grain in all, in THOMSON's original submarine telegraphic mirror instrument.

THE communication by M. ANDRÉ to the Academie des Sciences, on the study of atmospheric electricity, a translation of which we print in another column, should encourage the attempts of rain-makers. The author finds that the curves of the weight of water vapour are sensibly parallel to those of electric potential; but the former appear to lag behind, and, therefore, may be assumed to be the effect of which the electric changes are the cause. We presume that no rain-maker attempts to create aqueous vapour, but pretends to precipitate it in the form of a shower. There are sound reasons for supposing that such precipitation can be produced by electrical discharges, but it is difficult to calculate the scale on which such discharges should be carried out. A WIMSHURST machine on the scale of FERRANTI's largest dynamo might serve for the four-mile radius, but who would decide when it should be used? The County Council would doubtless be ready to place the matter in the hands of a Committee, though it would, perhaps, be better for the Government to appoint a Minister of Meteorology. We do not envy the responsibility which would attach to the post during Henley week.

Personal.—Mr. Alfred E. Ruddock, who has been for some years with Messrs. Goolden and Co., has joined the staff of Messrs. Poole and White.

Vienna.—It has been decided to light the Bourse by electricity; arc lights are to be used in the halls and vestibules, and incandescents in the rooms.

Telephone Trunk Wire Development.—A third telephone wire is now being erected between Paris and Brussels, and the line is being extended to Antwerp.

Littlestone-on-Sea.—This seaside resort, between Dungeness and Folkestone, has been granted an Act of Parliament for the erection of a pier and an electric tramway.

Telephone Trunk Wires in South Germany.—The telephone line between Munich and Stuttgart (125 miles) started working on the 1st inst. One shilling is charged for five minutes' conversation.

Digitized by Google

Electric Railway in Württemberg.—According to the *Elektrotechnischer Anzeiger*, the Municipal authorities of Württemberg have decided on building an electric railway between Meckenbeuren and Tettnang.

Arco.—The Town Council of Arco have commissioned Messrs. Kremenezky, Mayer and Co., of Vienna, to light the town by electricity. Continuous current 150 volt dynamos, driven by turbines, will run glow lamps for the street lighting.

Proposed International Electrical Exhibition at Melbourne.—It is proposed to hold a large International Electrical Exhibition at Melbourne about the end of the present year. The Exhibition will be held in the building used for the Centennial Exhibition of 1888.

City and Guilds of London Institute.—The next entrance examination for the Central Institution will be held on September 21—24th; and for the day department of the Finsbury Technical College, on September 29th. Further particulars will be found in our advertisement columns.

Projected Electric Railway in Italy.—*L'Eletricità* states that a project for the construction of an electric railway from Aosta to the borders of France and Switzerland at Pre Saint Didier, a distance of between 20 and 30 miles, has been laid before the Italian Minister of Public Works. This would be by far the longest electric railway in Europe. Water power would be employed.

Clerkenwell Vestry.—At the last meeting of this Vestry a letter was read from the Brush Electrical Engineering Company, giving notice of their intention to apply for a Provisional Order to supply electricity within the area of Clerkenwell. Similar letters were read from the County of London Electric Lighting Company and the Camberwell and Islington Electric Light and Power Company.

Electric Signalling at Henley.—At the Henley meeting, this week, a new departure was made by the adoption of electric signalling, in addition to the big bell on Frog Island, and the firing of a gun at the starting of each race. To every fifth pole on the Berks side of the river an electric bell was attached, which was set ringing two minutes before the start, and stopped the moment the oars touched the water.

The Electrical Equipment of the ss. "Scot."—In a paragraph on this subject in *The Electrician* of 26th ultimo it was stated that the measuring instruments of the "Scot" had been supplied by Messrs. Siemens Brothers. We are asked to modify that statement to the extent of saying that the voltmeters used in the "Scot's" electrical equipment are of Sir Wm. Thomson's marine type, and were made and supplied by James White, of Glasgow.

Burton.—At a recent meeting of the Town Council, the Gas and Electric Lighting Committee presented a report in which they asked permission to proceed to carry out the provisions of the Burton-upon-Trent Electric Lighting Order, 1890, to obtain a site for electric lighting works, and to advertise for tenders and proposals for electric lighting systems, the execution of works, and the supply of machinery, at a fixed sum. The report was adopted.

Anti-Magnetic Alloys for Watches.—The following names have been given to alloys suitable for manufacture of anti-magnetic watches:—(1), Mangor, an alloy of manganese and gold; (2), volfor, an alloy of wolfram and gold; (3), woltine, a gold platinum alloy; (4), cadmine, a hard and very elastic cadmium compound; (5), aror, an alloy of gold, cadmium, and manganese; (6), manium, an alloy of manganese, platinum, bismuth, and copper.

Electrical Bills in Parliament.—The London County Council's Overhead Wires Bill received the Royal Assent on Friday last. Petitions praying to be heard against the London County Council General Powers' Bill, when it reaches the Committee stage of the House of Lords, have been presented by the London Electric Supply Corporation and the Westminster Electric Supply Corporation.

Institution of Electrical Engineers.—The annual *conversazione* of the Institution of Electrical Engineers was held, on Monday evening last, in the galleries of the Royal Institute of Painters in Water Colours, Piccadilly. About 800 guests accepted the invitation of Prof. Crookes and Mrs. Crookes. Amongst those present were:—Sir F. Abel, Sir J. Douglass, Sir W. Thompson, Sir Benjamin Baker, Sir Philip Magnus, Sir E. J. Reed, Dr. Hugo Miller, and Herr Ganz.

Insulating Suspension for Arc Lamps.—A swivel suspension insulator has been designed by Mr. J. Raeburn, of Glasgow. A hollow casting, not unlike an inverted inkpot, contains five balls of glass or porcelain, and these form a ball bearing for a hook on which the lamp hangs. The insulation of such a swivel should be good, as the balls are well protected; but a shackle is generally sufficient, and a swivel would frequently giev trouble by allowing the leads to twist together.

Hampstead Vestry.—The draft Provisional Order prepared by the Electric Lighting Committee of this Vestry will be discussed on the 22nd inst. Notices have been served by the following companies of their intention to apply to the Board of Trade for Provisional Orders to supply electricity in this parish, viz.:—The House-to-House Electric Light Supply Company, the Hampstead Electric Light and Power Supply, the Hampstead Electric Supply Company, and the County of London Electric Lighting Committee.

The City Lighting.—At the last meeting of the Commissioners of Sewers, the Clerk said he had received a notice from the Brush Electrical Engineering Company of their intention to apply for a Provisional Order authorising them to supply electrical energy for public and private purposes within the City of London. Also a notice from the Laing, Wharton, and Down Construction Syndicate, of their intention to apply for a Provisional Order authorising the said Syndicate to amend the City of London (East District) Electric Lighting Order, 1890.

Railway Electric Lighting Plant.—At the Government dockyard at Port Adelaide there is in course of construction a travelling electric light plant for use on the railways. It consists of an ordinary locomotive engine, a truck upon which is fitted a portable engine and the dynamo, and the weed-stripper, which is used for clearing the railway lines of undergrowth. The plant, when completed, will be used to enable the navvies to carry on their work as much as possible at night, when their operations will be less hampered by the train traffic than during the day. Telegraph poles, upon which the wires are carried and the lamps hung, will be erected at each halting-place where their services are required.

Electricity in Collieries.—Electricity, says the *Colliery Manager*, has again given a most satisfactory account of itself as a valuable adjunct to coal-mining plant. Recently a very large feeder of water broke away at one of the pits of the East Howle Colliery, Ferryhill. If it had not been for the good service rendered by the new electric plant, lately supplied by Messrs. Mercier, Corlett, and Co., Wigan, one seam must have been drowned out. The pump ran for 82 hours, only stopping twice in 24 hours, and then for a few minutes, only to change brushes. In that time, Mr. Henry Palmer, the manager of the colliery, informs us it pumped 2,700,000 gallons, or equal to 12,000 tons of water.

Electric Launches on Lake Windermere.—Several launches have been introduced on to Lake Windermere by the General Electric Power and Traction Company. The boats are those which plied at Edinburgh during the Exhibition, and have a light and graceful appearance on the water. Each is 40ft. in length, 6ft. 6in. beam, and licensed to carry 40 passengers, the speed attained being about eight miles an hour. The seats run the entire length of the vessels, beneath which are the storage batteries. The dynamo for generating the power required is erected near to Cockshott Point, and is driven by a 16 H.P. Roby steam engine, and, in addition to this, the water power of a neighbouring mill has been secured.

Hove.—In January last the Hove Commissioners decided that the electric lighting of Hove should be carried out by a transfer of the powers under their Provisional Order to some responsible company, and that an electrical engineer should report on the best system to be adopted, specify the plant required, and should advise as to the terms to be offered to a company. Mr. Crompton was the engineer selected, and the Electric Light Committee has had many meetings on the subject. The result is a report which was to come before the Commis-

Digitized by Google

sioners yesterday. The Committee are of opinion that the three-wire system, with storage, should be adopted. On the subject of plant the Committee rely upon Mr. Crompton's recommendations.

Rapid Transit in Cities.—In the discussion of a recent Paper read before the American Institute of Electrical Engineers on rapid transit in cities, Prof. Forbes called attention to the fact that the English had apparently outstripped the Americans in rapid transit matters. "We have heretofore called attention," says the *Western Electrician*, "to the progress that has been made on the other side, especially in the London underground system. It appears that our friends across the water are thoroughly enjoying the situation, and taking all the comfort possible from the thought that they have at last surpassed their American rivals. One cannot wonder at this. It is a rare spectacle, and probably the one occasion of a lifetime for our English friends."

Brighton.—The works in connection with the electric lighting of Brighton by the Corporation are rapidly approaching completion. The generating station in North-road is practically finished. In the boiler-house there are three mild steel Lancashire boilers, and there is space for another set. In the engine-room there are four 165-unit dynamos, coupled direct to Willans engines. Overhead there is a 6-ton travelling crane. In the engine-room space has also been reserved for doubling the number of dynamos and the engines. In the battery-room the stands to receive the accumulators have been placed in position. The street mains comprised in the existing scheme have all been laid, with the exception of the branch passing along the Western-road to the western boundary of the borough.

The Frankfort Exhibition.—The following circular has been sent by the Secretary of the London Chamber of Commerce to members of the Electrical Trade Section :—

Dear Sir,—At the recent meeting of the Electrical Section of this Chamber, one of the subjects discussed was the formation of a party to visit the Frankfort Exhibition. It was generally felt that there were greater privileges and facilities afforded in the way of guides, &c., when the visit took the form of a representative party than there would be in the case of a visit as private individuals. The authorities of the Exhibition have been communicated with, and have expressed themselves favourably towards the proposed visit, which would probably extend from the 5th to the 15th of September. With the view of determining whether the visit can be made in the form of a party, I should be pleased to hear from you at your earliest convenience as to whether you propose to visit this Exhibition or not, and, if so, whether you would wish to become one of the party, and if the date named (5th to 15th September) would be suitable for you.

The Chicago Exhibition.—In the House of Commons last week, Mr. Grotrian asked the Under-Secretary of State for Foreign Affairs whether the report was true that the Government intended spending on the Chicago World's Fair an amount less than half the sum set apart for the Paris Exhibition; and whether it was their intention to give the management of the British section to the Society of Arts, and not to a Government department. In reply, Sir J. Fergusson stated that the arrangements were not made by the Foreign Office; but he believed that provision was likely to be made for a Royal Commission to provide for the representation of this country at the Chicago Exhibition at a lower cost than at the French Exhibition of 1878.

Aluminium.—With the price of aluminium reduced only a very little from present rates, says the *Mining Journal*, there is a strong probability of aluminium-bronze very largely displacing brass. A small percentage of aluminium to Babbitt metal gives results which in many classes of work are largely superior to those obtained from ordinary Babbitt metal. Aluminium is being largely adopted as a material in the railroad shops of the United States. It is being employed in the construction of the valves to control the passage of the air from the storage cylinders to the brake cylinders in the new and larger form of the Westinghouse brake; and for this purpose its lightness gives it an important advantage over the heavy iron or brass slide valves. The valves of the pure metal in sample castings appear to have satisfactorily answered their purpose, and, with the addition of a little copper, there is no question of the efficiency of aluminium in this and other engineering employments.

Electric Traction in Boston.—Electric traction is apparently a success in Boston, if we may judge by the following extract from a Boston technical contemporary :—"With the electromotive force and the palatial street-car equipment now on our streets, Boston can vie with any system of street-car traction on the continent. A system thoroughly established by masterly effort and unswerving energy, measured by public appreciation and a greatly increased patronage, the West End system rests upon an assured stability that places it as the foremost street-railway property in this country. Statistics are not wanting to prove the greatly increased traffic of the West End system. The evidences are in sight. The popular clamour to ride in a palatial street car is heard and seen on all our avenues and throughout all of Boston's suburbs, proving the advantages of the subtle element, the unseen power of quick transit, and the ability given the Company to cope with the demands of an ever-increasing population."

Telluric Non-Conducting Cement.—In the present day of small profits, says the *Chemical Trade Journal*, it has become necessary for all those who require steam as a means of heating and power to obtain their steam under those conditions which develop the maximum efficiency of the boilers. The importance of giving due attention to the covering of boilers, and steam-pipes in particular, is especially great in works where the steam has to be conveyed long distances. The enormous loss of steam, owing to condensation in such cases, is alarming. A non-conducting medium must not only be an efficient non-conductor, but must also set well, without cracking, be impervious to the action of rain and atmospheric influences, neither fire nor char, and last, but not least, the price must be within reason. Telluric cement combines these properties as much as is possible. It is strong and adhesive, and sets firmly, and, therefore, in all cases where vibration is likely to occur it is eminently suitable. As regards its non-conducting properties, it is admitted to be slightly less efficient than the best real asbestos coverings, but then it is much cheaper.

Gas v. Electric Light in New York.—Statistics prove that the growth of gas consumption in New York City, for 40 years prior to the introduction of electricity for lighting purposes, averaged about 10 per cent. per annum. That is, the gas output doubled every 10 years, and that the city had doubled in population every 17 years. Since the first introduction of the electric light, however, the increase in New York of the consumption of gas had been much more rapid. It almost immediately jumped up to 12 per cent. per annum, and in 1887 showed a growth equal to about 14 per cent. per annum, a ratio of growth that was still further exceeded in the years 1888-89-90 The gas output of New York is doubling itself now in a period of six and one-half years, instead of 10 years as before. The President of the Standard Gas Company thinks that one reason for this very rapid increase is due to the fact that the electric light has educated the human eye "in the aggregate" for a demand for more light, and that people are not at all satisfied with the volume of light that formerly satisfied them.

The Reactions in the Aluminium Electrolytic Process.—The character of the reaction in the chief process by which pure aluminium is produced on a commercial scale in Europe and in this country, has, says Mr. Alfred H. Bucherer, in the *Engineering and Mining Journal*, been the subject of discussion among metallurgists and chemists, but often opinions have been passed on it which prove the lack of thorough study and of practical investigation. I have had opportunity to see this process worked for a long space of time, and have experimented largely with the great facilities offered by the plant of the Cowles Company and of the Pittsburg Reduction Company, and therefore think I may be able to throw some light on this interesting question. In my opinion the cycle of reactions by which aluminium is produced in the various electrolytic processes, in whatever form they may appear, is the following: The current acts on the aluminium fluoride, aluminium is deposited at the cathode and fluorine at the anode. The free fluorine at once exerts its affinity for the aluminium in the alumina, and with the help of carbon forms aluminium fluoride, and at the same time carbonic oxide is formed. The aluminium fluoride, in turn, is decomposed.

Glasgow.—The City Engineer has supplied the Electric Lighting Sub-Committee with particulars as to ground belong-

Digitized by Google

ing to the Corporation and the Improvement Trustees. At the meeting of the Sub-Committee, held last week, a letter was read from Messrs. Fawcus and Cowan with reference to utilising the Falls of Clyde for generating electricity for the supply of the city. The Sub-Committee instructed the Town Clerk to state, in reply, that a proposal of the same nature was some time ago brought before the Town Council, but was not entertained by them. A communication was also read from Messrs. S. Z. de Ferranti with reference to adopting the high-tension alternating-current system for the lighting of the central and outlying areas of the city, instead of the low-tension continuous-current system. The Sub-Committee instructed the Town Clerk to intimate to Messrs. de Ferranti that the proposal contained in their letter could not be considered. The Sub-Committee afterwards resolved to recommend that a permanent electrical engineer should be appointed by the Town Council. At their meeting held this week, the Sub-Committee agreed to recommend that the salary to be offered to the electrical engineer should commence at £250 per annum.

The Fatigue of Metals.—With respect to statements that occasionally appear on the subject of the fatigue of metals under long-continued stress, a report that has recently been published regarding two similar suspension-bridge links is worthy of notice. A square iron link, 12in. wide, 1in. thick, and about 12ft. long, was taken from a bridge at Kieff, then about 40 years old, and tested against a similar link which had lain unused in store ever since the building of the bridge. The means of comparison were, therefore, excellent, and the result should go a long way to show whether or not iron really does lose any of its strength in prolonged service. The effect of the tests was to determine for the old used link an ultimate tensile strength of 21·8 tons per square inch, an elastic limit of 11·1 tons per square inch, an elongation of 14·05 per cent., and a contraction of 17·35 per cent. at the point of fracture. For the unused link, the tensile strength was found to be 22·2 tons per square inch, with an elastic limit of 11·9 tons, and elongation and contraction at fracture of 18·42 per cent. and 18·75 per cent. respectively. The two pieces of iron were, therefore, of practically identical strength; for the small difference actually observed is well within the ordinary range of variability of similar pieces of the same metal.

New Cross Technical and Recreative Institute.—This Institute will be opened by the Prince and Princess of Wales on the 22nd inst. Amongst the appointments already made are the following:—Head of Engineering Section: Mr. W. Lineham, M.I.M.E., late Professor of Engineering at the Newcastle-on-Tyne School of Science and Art. Assistant Instructor: Mr. H. Ashton, foreman in pattern-making department at the Brush Electric Light Company's workshops. Head of Chemistry Section: Mr. A. Bloxam, F.I.C., late Demonstrator of Chemistry, Royal Agricultural College, Cirencester. Mathematical Lecturer: Mr. J. Taylor, assistant lecturer at the City and Guilds Technical Institute. Lecturer (Electrical Section): Mr. W. Slingo, Principal of the Telegraphists' Central School of Science. Assistant: Mr. A. Brooker. The classes will begin on October 1st, and the Session will last about seven months. The following are some of the classes which will be ultimately formed:—Brass Finishing and Fitting; Chemistry (practice and theory); Engineering (practice and theory); Electrical Engineering (practice and theory); Mathematics; Magnetism; Machine Drawing and Construction; Mechanics (theoretical and applied); Metal Plate and Zinc Working; Metal Turning and Fitting; Metallurgy; Physics; Steam; Tanning; and Telegraphy.

Damage by Lightning.—During a thunderstorm which broke over the village of Montacute (Somerset), last week, a splendid cedar on St. Michael's Hill, conspicuous in the district for several miles round, was completely shattered. The tree was about 90ft. in height and about 14ft. in circumference at the base. The discharge, after shivering the top into several pieces, ran down the trunk, splitting it into two parts, nearly 50ft. in length. On Monday a thunderstorm broke over Buckingham. The lightning struck one high-pitched roof of the Congregational Church, and damaged both sides of it. Flames almost immediately shot up from the roof, but the fire brigade soon got the fire under. On Wednesday a thunderstorm broke over the northern portions of London. At Tottenham High Cross three houses were struck by the lightning and considerably damaged, one being set on fire. The Seven Sisters Hotel was also struck, and a large chimney stack and a considerable portion of the roof was demolished. At Edmonton a labourer, who was haymaking, took shelter under a tree, when he was struck by the lightning. The man's clothes were torn into ribbons. At Chicago, on Monday, during a heavy storm, the recently imported balloon in the grounds of the World's Fair was struck by lightning and destroyed. The aeronauts were severely injured.

The Five-Wire System in Paris.—With the exception of the Vienna and Königsberg stations, the 45,000 light station, supplying the Place Clichy sector, which was recently inaugurated, is the only one of its kind in Europe. The Paris station has three floors, and covers a superficial area of 19,800 square feet. In the basement is the boiler plant, which comprises six of the Naeyer multitubular type. The ground floor is occupied by the steam piping, while on the first floor are placed the engines, dynamos, and the distributing board. The generating plant comprises three 150 H.P. Armington and Sims engines, each belt driving two shunt-wound dynamos, and three 500 H.P. Corliss engines, running at 64 revolutions, and each of which is coupled direct to a 350 kilowatt (700 amperes × 500 volts) eight pole machine. The armatures of these dynamos are 11ft. in diameter, and the brushes bear on their exterior. A 250 cell battery of Laurent-Cely accumulators supplies current during the night. The district supplied by this station has an area of nearly two square miles, and the most distant feeding point is 2,750 yards away. To keep the pressure on the different branches at the proper value six sets of automatic apparatus are employed. The mains are all lead-covered, iron-armoured Siemens cables. Aron meters are employed, and are modified to suit the exigencies of five-wire distribution, that is to say, the coils are arranged so that the current in the two outer leads exerts double the magnetising influence of the current in the two adjacent leads, the central wire not passing through the meter at all. The Société Alsacienne de Constructions Mécaniques is responsible for the erection of the whole system.

Transmission of Power at Locle.—The following are some further particulars of the interesting little transmission of power plant at Locle, which was briefly alluded to in *The Electrician* of July 25, 1890. In December, 1887, the Communal authorities of this great Swiss watch-making district invited tenders for the erection of an electric light and power plant, and the plans of MM. Cuerrod et Sautter, of Geneva, were accepted. The specifications required the supply of 50 H.P. for eleven hours each day, and current sufficient for 2,500 10 c.p. lamps for five hours. The motive power was to be derived from the Bied, two miles distant, where a head of 300ft. and an average flow of 24½ gallons per second were available, and where a reservoir of 2¼ million gallons capacity was to be built. The contractors decided to adopt the three-wire system, and a difference of potential at Locle of 300 volts, 150 volt lamps being employed, the smaller motors being taken off the 150 volt leads, and the larger ones being connected across the external wires. Taking the minimum flow at 3 gallons per second, the effective head at 280ft., and the efficiency of the turbines at 75 per cent., some 1,750 H.P. hours are rendered available in 24 hours. Now, 50 H.P. for 11 hours, *plus* 2,500 3¼ watt lamps for five hours, demand some 1,200 H.P. hours; so that the daily allowable loss in the dynamos, line, and network is 550 H.P. hours, or 32 per cent. As a matter of fact, the loss in the line at full load amounts to 48 H.P. The plant comprises one 220 H.P. horizontal turbine, coupled direct to two 80 kilowatt Thury dynamos, one 30 H.P. turbine coupled direct to two 10 kilowatt machines, a reserve 80 kilowatt turbo-dynamo, and a 100 H.P. steam engine. Automatic speed regulators for the turbines, and automatic field resistance regulators for the dynamos, are employed. The largest size motor allowed is of 6 H.P. The prices charged vary according to the size of the motor and to the method of payment; thus, a one horse power can be had for £20 a year, or for 9d. an hour by meter. The price seems to us to be prohibitive, especially where labour is comparatively cheap.

MAGNETISM IN IRON AND OTHER METALS.*—XLIV.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 182.*)

§ 154. **Equation of the Magnetic Circuit.**—Returning now to the case of a perfect magnetic circuit, we have to consider the connection of the magneto-motive force or line integral of magnetic force along the circuit and the magnetic flux. Suppose the circuit to be divided up into a number of tubes of induction, in any one of which the cross-section is small, so that **B** and **H** may be taken as uniform over any one cross section of the (small) tube. The relation which we establish for each small tube may easily be extended to apply to the whole magnetic circuit, which is built up of such small tubes placed side by side. Let s be the area of cross-section at any part of the small tube, and **B** the magnetic induction there. The flux in the tube is $\mathbf{B}s$. If μ be the permeability of the substance, the magnetic force **H** at the same place is $\frac{\mathbf{B}}{\mu}$; hence

$$\frac{\text{flux}}{\mu s} = \frac{\mathbf{B}}{\mu} = \mathbf{H}.$$

Multiply each side by an indefinitely short length of the tube dl—

$$\text{flux}\,\frac{dl}{\mu s} = \mathbf{H}\,dl.$$

Integrate both sides, remembering that the flux is constant at all sections;

$$\text{flux} \times \int\frac{dl}{\mu s} = \int \mathbf{H}\,dl = \text{magneto-motive force},$$

when the integration is extended round the whole circuit;

hence,
$$\text{flux} = \frac{\text{magneto-motive force}}{\int\frac{dl}{\mu s}}.$$

The meaning of the denominator may be most readily seen if we write ρ for $\frac{1}{\mu}$ and call ρ the *specific magnetic resistance* of the substance. Then $\frac{\rho\,dl}{s}$ is evidently the magnetic resistance of that portion of magnetic circuit which has the length dl and the cross section s. The idea of magnetic resistance is introduced here in a sense strictly analogous to the idea of electric resistance in the electric circuit. The specific magnetic resistance ρ is the analogue of the specific resistance to conduction—namely, the resistance of a piece of the conductor of unit length and unit areas of cross section. The quantity $\int\frac{\rho dl}{s}$ is simply the sum of the resistances of successive short portions of the length of the circuit. We may, therefore, write the equation of the perfect magnetic circuit thus,

$$\text{flux} = \frac{\text{magnetomotive force,}}{\text{magnetic resistance of the circuit,}}$$

which is the magnetic analogue of the familiar equation of conduction

$$\text{current} = \frac{\text{electromotive force}}{\text{conduction resistance of circuit.}}$$

There is, however, this reservation to be borne in mind in pursuing the analogy. In the conduction circuit the specific resistance of the material is not a function of the current, that is to say, its value is independent of the amount of the current. In the magnetic circuit ρ and μ are functions of the flux, for they depend on the value of **B**. More than that, they may have many possible values even when the value of **B** is assigned, for they depend not only on the existing magnetic induction, but on the previous magnetic history of the piece. But the equation of the magnetic circuit will be correct and intelligible if we define μ as nothing more or less than the value which the quotient $\frac{\mathbf{B}}{\mathbf{H}}$ happens to have at that place in the circuit to which reference is made, and if we define ρ as the reciprocal of that quantity, or $\frac{\mathbf{H}}{\mathbf{B}}$. We may have a magnetic circuit in which there is no magneto-motive force, but in which there is (residual) magnetic flux. In that case the "magnetic resistance" of the circuit must vanish, and the mean value of ρ must be zero. We may even have a magnetic circuit in which the direction of the flux is (on account of past magnetisation) opposite to the direction of the magneto-motive force, which implies a negative value of μ and of ρ.

In most of the cases to which the conception of the magnetic circuit may be usefully applied, the effects of previous magnetisations are absent or negligible, so that the values of μ which are to be used, are the permeabilities which are derived from the ordinary curve of magnetisation (for the particular material of the circuit), that is to say, from the curve which expresses the relation **B** to **H** when **H** is progressively increased from zero and the metal is free of magnetism to begin with.

In many instances the circuit may be treated as (very approximately) made up of a series of portions, in any one of which μ is constant and s is constant. Thus, calling l_1 the length of one of these portions, μ_1 its permeability, and s_1 its cross-sectional area, l_2 the length of the next, μ_2 its permeability, and s_2 its sectional area, and so on, we have

$$\text{flux} = \frac{\text{magnetomotive force}}{\frac{l_1}{\mu_1 s_1} + \frac{l_2}{\mu_2 s_2} + \frac{l_3}{\mu_3 s_3} + \&c.},$$

as many terms being taken in the denominator as are needed to complete the circuit.

And if the object is to express the value of the induction at any place in the circuit in terms of the magnetomotive force, we have only to divide the flux by the area of cross-section there. Thus, if it is wished to express $\mathbf{B}_1$, the induction in the first portion of the circuit, where the area of section is s_1, we have

$$\mathbf{B}_1 = \frac{\text{flux}}{s_1} = \frac{\text{magnetomotive force}}{\frac{l_1}{\mu_1} + \frac{l_2}{\mu_2}\cdot\frac{s_1}{s_2} + \frac{l_3}{\mu_3}\cdot\frac{s_1}{s_3} + \&c.},$$

Or, again, if what is wanted be to calculate the number of ampere turns which are required to produce a stated magnetic flux in a magnetic circuit made up of a series of portions of which the lengths, sections, and permeabilities are known, we may find the magnetomotive force from the formula

$$\text{Magnetomotive force} = \text{flux}\left(\frac{l_1}{\mu_1 s_1} + \frac{l_2}{\mu_2 s_2} + \frac{l_3}{\mu_3 s_3} + \&c.\right),$$

and then find the number of ampere turns by dividing their magnetomotive force by $0{\cdot}4\pi$. This is, in effect, the problem which is attacked in calculating the winding of the field-magnets of a dynamo. The problem is analogous to that of finding the electromotive force necessary to drive a stated current through a circuit composed of a series of conductors of which the specific resistance, the length, and the cross section, are assigned.

§ 155. **Particular Cases: Continuous Ring wound uniformly and otherwise.**—The utility of the idea of the magnetic circuit will be apparent when we consider one or two examples. Take first the case, already familiar, of a uniform ring uniformly wound with a magnetising coil of N turns. Let l be the length of the ring, measured round any circle within the ring parallel to the sides. The magnetic force at all points of such a circle is $\frac{4\pi\,\mathrm{C\,N}}{l}$, and the line integral of this, or the magnetomotive force, is $4\pi\,\mathrm{C\,N}$. If s be the area of cross section, the magnetic resistance of the ring is $\frac{l}{\mu s}$, and the flux, which is equal to the magnetomotive force divided by the resistance, is—

$$\frac{4\pi\,\mathrm{C\,N}}{\frac{l}{\mu s}}$$

* All rights are reserved.

Digitized by Google

We might, of course, have derived this expression for the flux otherwise, namely:—

$$\text{Flux} = \mathbf{B}\, s = \mu\, \mathbf{H}\, s = \frac{4\pi\, C\, N\, \mu\, s}{l}.$$

The line-integral of magnetic force has the same value over all lines that thread through the magnetising coil. Moreover, the magnetic force **H** is itself constant at all points of the circle l, parallel to the sides of the ring; so that the line integral is $\mathbf{H}\, l$. To compare the values of **H** at different points in the substance of the ring, at distances r_1, r_2, &c., from the axis of the ring, we have $\mathbf{H}_1\, l_1 = \mathbf{H}_2\, l_2$, $l_1 = 2\pi r_1$, and $l_2 = 2\pi r_2$; hence, $\mathbf{H}_1\, r_1 = \mathbf{H}_2\, r_2$. In other words, the magnetic force, due to uniform winding on a uniform circular ring, varies across any section in inverse proportion to the distance of the point from the axis of the ring. (*See* § 57 above.)

In the case of a uniformly wound uniform ring there is no special advantage in applying the conception of the magnetic circuit. The results to which it leads are obtained, with no less ease, by considering the magnetisation and magnetic force at any individual point of the metal. But it should be noted that the conception of the magnetic circuit makes it possible to avoid any use of, or reference to, the quantity **H**. We have derived the notion of magnetomotive force from that of magnetic force, by taking the line integral of **H** round the magnetic circuit. But that is by no means a necessary order of ideas; nor is the notion of **H** indispensable in the treatment of the subject. The magnetomotive force may be defined without reference to it, and the flux may be stated in terms of the magnetomotive force and magnetic resistance, so that all use of **H** may be excluded. It is even theoretically possible to treat all cases of magnetisation in the same way:—with a magnetised bar, for instance, the magnetic circuit is completed through the surrounding non-magnetic medium, and a sufficiently powerful analysis might determine the resistance of the circuit, and so allow the relation of magnetic flux to magnetomotive force to be treated without any allusion to the magnetic force at individual points of the bar. But to apply this method universally, though theoretically possible, is quite impracticable; and there are very many problems in regard to which the older modes of viewing the subject, described in earlier articles of this series, are infinitely more convenient. The student must not think to abandon the consideration of magnetic force and magnetisation at individual points because he finds that the notion of the magnetic circuit is remarkably useful in certain cases, and has, in theory, no limits to its application. Its real value lies in the fact that by the help of it problems which would otherwise be intractable may be solved with sufficient exactness for practical purposes. To trace, for example, from point to point in the core of a transformer or the field magnets of a dynamo the value of **H**, and so determine the magnetisation, would be a task the difficulty of which would be prohibitive. But by applying to such cases the method of the magnetic circuit, a solution is readily arrived at—not, indeed, a rigorous solution, but one that satisfies the requirements of the electrical engineer.

In the case dealt with above—that of a uniform ring uniformly wound—the metal of the ring forms a perfect magnetic circuit. None of the lines of induction stray into surrounding space; the ring itself is a tube of induction, and the flux is constant at all cross sections.

Suppose, however, that, instead of being uniformly wound, part of the ring, Q, is bare and the magnetising coil is heaped up on the other part P (Fig. 131). In that case the flux through P is greater than the flux through Q, for some of the lines of induction which thread through the coil close themselves by passing not through the bare part of the ring but through surrounding space in the manner indicated by the dotted lines. The ring is now an *imperfect* magnetic circuit. If, however, the material is very permeable, like soft wrought iron (the magnetic permeability of which, when not too strongly magnetised, is some two or three thousand times as great as permeability of air), and if the ring is short, this leakage of lines of induction into surrounding space will take place to only a very limited extent; by far the greater number of the lines through P will complete their circuit within the substance of the ring, and the flux at Q will be only a very little less than the flux at P. We may, therefore, in such a case, as a first approximation, treat the flux in the ring as constant, and apply the equation of the perfect magnetic circuit, flux $= \frac{4\pi C N \mu s}{l}$, to find it. This quantity is, in fact, slightly less than the flux in the part P, because the resistance of the actual magnetic circuit is a trifle less than that of the ring, through the "shunting" of a part of the ring by the surrounding air. On the other hand, the flux, as calculated above, is greater than the true flux at Q.

The case is analogous to that of a conducting circuit, which instead of being perfectly insulated is immersed in a poorly conducting fluid. Imagine a ring of copper with a seat of electromotive force at P to be immersed in a liquid, the conductivity of which is only one two-thousandth or one three-thousandth that of the copper. The current at Q will be only a little less than the current at P; the current which leaks into the surrounding fluid will be an inconsiderable part of the whole. We must repeat the proviso that the ring is short; in other words, that the surface through which leakage occurs is not very great in comparison with the area of cross section through which what we may call legitimate conduction occurs.

The advantage of regarding the iron ring as a magnetic circuit, nearly, though not quite, perfect, is at once apparent when one considers how difficult it would be to determine directly the

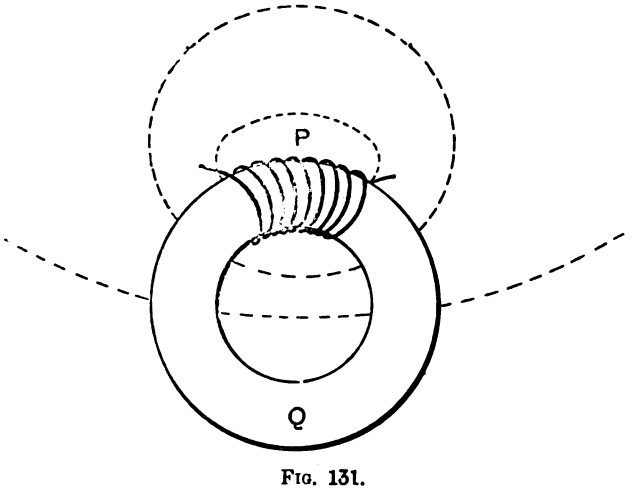

Fig. 131.

magnetic force **H** at individual points. In the case of a uniformly wound ring there was no difficulty in determining **H**, because it was wholly due to the magnetising coil. In the present case **H** is by no means due to the coil only. The coil acting alone would produce a strong magnetic force at points within and close to it, and would produce very little magnetic force in more distant portions of the ring. But we know that **H** must actually be pretty nearly uniform throughout the ring, because the magnetisation is pretty nearly uniform. What tends to equalise **H** is the free magnetism in the ring itself—the free magnetism which exists in consequence of the very fact that the flux is not quite uniform.

The magnetic force at any point is due partly to the action of the free magnetism and partly to the action of the coil; at points within and near the coil the free magnetism diminishes **H** by opposing the action of the coil, but augments **H** at points on the bare side of the ring. It is just because the ring is not a perfect magnetic circuit—because there is some leakage of the flux into surrounding space—that the magnetic force (and, therefore, the induction) is fairly uniform all round. In a short ring of very permeable substance, a slight variation in the flux from point to point of the ring will imply enough free magnetism to correct very nearly that excessive inequality in the magnetic force which is produced by the magnetising coil; in other words, the circuit then establishes itself with but little leakage.

(To be continued.)

CAPACITY TESTS.

BY ARTHUR DEARLOVE.

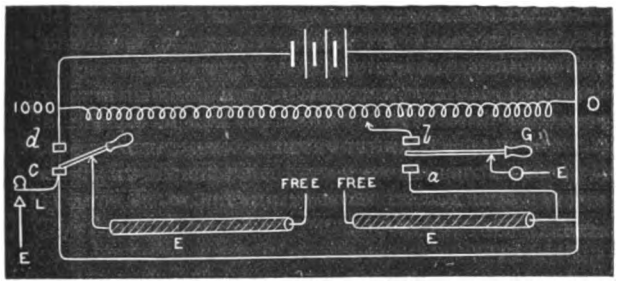
The following modification of "Gott's Test" for comparing or determining the capacity of Cables was suggested to me by Mr. Herbert Taylor. I have tried the test and obtained satisfactory results.

For the comparison of condensers or for finding the capacity of a cable when a condenser is used as a standard the test has no advantages over the Gott's method, but the value of the suggestion consists in the fact that with duplicate cables the position of a ruptured conductor or their relative capacity is quickly and accurately found.

The test is practically an "electrostatic loop test," and the following diagram shows the plan of connections; it is, perhaps, a little more complicated than the original method, but will be easily understood by those familiar with "Gott's Test," and with the method of finding the correction for absorption and eakage suggested by Dr. Muirhead.

It is essential in this test that both the battery and slides should be very carefully insulated, or wrong values will be observed. The correction for difference of absorption or leakage can be observed in much the same manner as described in *The Electrician* of March 6, 1891.

Having joined up, as shown, proceed as follows: First to make certain that the cables are thoroughly free of charge depress the key L, putting both cables to earth for a few seconds, then charge both cables by putting down key K, obtain balance at the end of any given number of seconds by trial and error, moving the index of slides until depressing key G gives no deflection.



In practice, I have found it most convenient to charge the cable for, say, five seconds, then instantaneously put galvanometer on to index of slides; if balance is not obtained, raise key K and depress key L before charging again—repeat the operation of charging until balance is found.

If there is no difference of absorption or of insulation resistance in the cables compared, no correction is necessary, and the observed standard resistance gives the correct ratio between the capacity of the two cables, so that knowing the capacity of either the capacity of the other is found.

Should there be a large difference in absorption, or should one cable be of low insulation, the correction desired is obtained in the following way:—

The condition of things being as in diagram, and the cables free of charge, charge them from the battery, as before, and at the end of, say, five seconds, put both ends of the cable together by key K; allow them to remain so, for, say, a period of three seconds, then discharge the cable through galvanometer to earth by raising key G, and note the deflection, say, *d*.

To obtain the value in slide readings of this deflection, the index of the slides is run back towards the end of slides marked O, and key G is depressed, placing galvanometer on to index, moving the index until the same deflection is produced—the standard resistance so observed is the correction, and is additive to the initial standard resistance at balance if in the same direction as throw *d*, subtractive if in the opposite direction.

Between each operation the key L should be put down for a few seconds to discharge the cables.

The two cables actually compared were coiled cables, one length on board ship and the other in the factory tank; their respective lengths were 360 and 255·5 knots.

No correction was observed, as the cables under comparison were of the same material and insulation resistance.

To imitate a cable with faulty insulation a leak of 1 meghon and in another instance of half a megohm, was put in on one section and the correction observed.

The results are given below:—

	Mfds.	Mfds.	Knots.
360 knots (capacity determined with standard condenser	30·76	= 131·57)	*versus* 2
Capacity at 75° in 2 knot lengths		= 130·59	

Ch. 5"	Bal. S.R.	Ratio of S.R.	Ratio of Cap. 75° value.	Ratio o length.
	5,864 no correction...	1·418	... 1·413	1·409

The capacity of the 255·5 knots, taking the 360 knots a s standard (131·5 mfds.) = 92·80 mfds., the capacity of the section being 92·53 by the tests at 75°

360 knots was then put to earth through one megohm.

Ch. in secs.	S.R. at bal.	Mixing period. secs.	Correction discharge.	Value in S. R.	Corrected S. R.	
5 ...	5,963 ...	3 ...	180 Z − ...	95 = 180 R ...	5,868	Slide reading taken as correct 5,864 as above.
½ megohm leak						
5 ...	6,059 ...	„ ...	80 Z − ...	187 = ...	5,872	

The corrected slide reading in both cases where leaks were inserted, agrees closely with the first standard resistance obtained at balance when both cables were under normal conditions, and gives the actual capacity of the section within small limits of error.

The test is applicable in many directions, which will suggest themselves to those interested in the question; for instance, two cables being compared frequently for a given time of charge, the slide reading at balance should always be constant; if a different standard resistance is observed at any time it may be inferred that the insulation of one or the other has probably altered.

This test is also a loss of charge test, and the correction found when both cables are of the same material is practically a measure of their respective insulation resistances.

Some time since attention was drawn to the value of the correction suggested, and I give the following figures obtained recently under the method now described in support of the opinion expressed in *The Electrician* of March 6 last.

Standard Condenser 30·763 mfds. versus 360 kts. cable.

Ch. secs.	S.R. at bal.	Mixing period secs.	Correction discharge in divs.	Equivalent in S.R.	Corrected S.R.	Capacity per kt.
5 ...	1,935 ...	3 ...	45 r ...	− 38 ...	1,897	Mean corrected slide reading 1.895 = 131·57 mfds. = 0·366 mfds. per kt.
10 ...	1,974 ...	3 ...	100 r ...	− 74 ...	1,900	
15 ...	1,993 ...	3 ...	51 ...	− 100 ...	1,893	
20 ...	2,035 ...	3 ...	70 ...	− 144 ...	1,891	
25 ...	2,059 ...	3 ...	82 ...	− 166 ...	1,893	
30 ...	2,084 ...	3 ...	102 ...	− 187 ...	1,897	

It is obvious that had the correction not been applied, a largely different value for the capacity of this section of 360 knots for each time of charge would have been accepted.

I may point out that no correction for leakage is found when the insulation resistance per microfarad is the same in the standard condenser and in the cable compared, but the correction becomes necessary when large differences of absorption exist between the two capacities under test.

Royal Institution.—At the general monthly meeting of this Institution, on Monday last, the special thanks of the members were returned to Miss Jane Barnard, Dr. J. H. Gladstone, the Rev. A. R. Abbott, Mr. T. F. Deacon, Mr. A. Blaikley, and others, for the loan of the valuable and interesting collection of Faraday memorials shown in the library on the occasion of the two lectures, on June 17th and 26th, given in commemoration of the Faraday Centenary. The special thanks of the members were also returned to Mr. Ludwig Mond for his donation of £100 towards expenses connected with the Faraday Centenary commemoration.

A CONTRIBUTION TO THE STUDY OF ATMOSPHERIC ELECTRICITY.*

BY C. ANDRÉ.

It is generally supposed that there is in the case of atmospheric electricity a normal diurnal variation, corresponding to calm weather and a clear sky. An investigation of the observations taken at Lyons since the year 1884, by means of the recording electrometer of M. Mascart, does not confirm this view of things. In fact, let us pick out from among the clear, calm, cloudless† days those on which the prevailing wind blows from the North or from the South (this is to say, nearly all), and let us determine the average daily variation in each of these cases for the spring, summer, and autumn. We obtain curves similar to those shown in Fig. 1, which bring to light a diurnal variation which is very different in the two cases, the amplitude of the day oscillation being three times as great as that of the nocturnal oscillation for a southerly wind, whilst for a northerly wind, on the other hand, it is the nocturnal oscillation which is treble that of the day. The addition to these calm days of fine days on which the wind blows more or less strongly (Fig. 2) does not change the general character of the daily variation, the characteristic differences which I have just pointed out persisting within sensibly the same limits. The so-called *normal* daily electrical variation is, therefore, the combination of two different states, corresponding, moreover, to two different distributions of pressure relative to the place of observation.

This conclusion is not limited to electric potential; the same method of separating out applied for the same days to barometric pressure, and to weight of water vapour contained in a given volume of air, bring to light for these two meteorological elements also two different daily variations. The phenomenon is especially striking in the case of weight of water vapour (Fig. 3), the daily variations of which are sensibly parallel to those of electric potential. In the same way the annual variations of relative humidity and electric potential are so very similar that their curves (Figs 4 and 5) seem to be traced from each other.

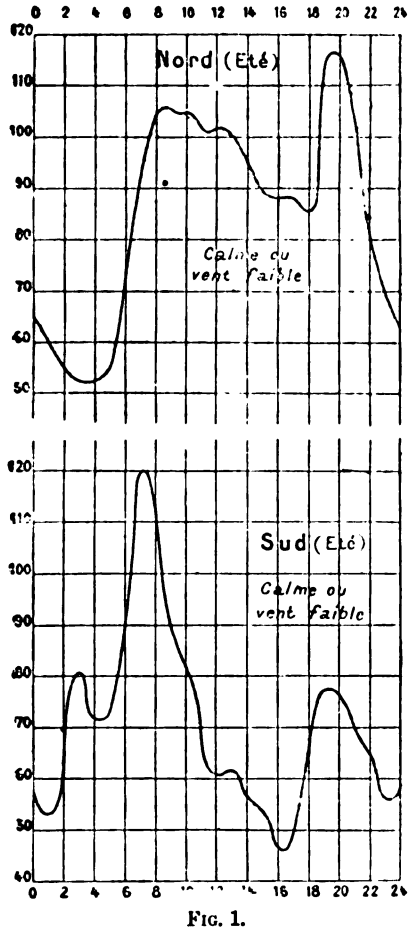

FIG. 1.

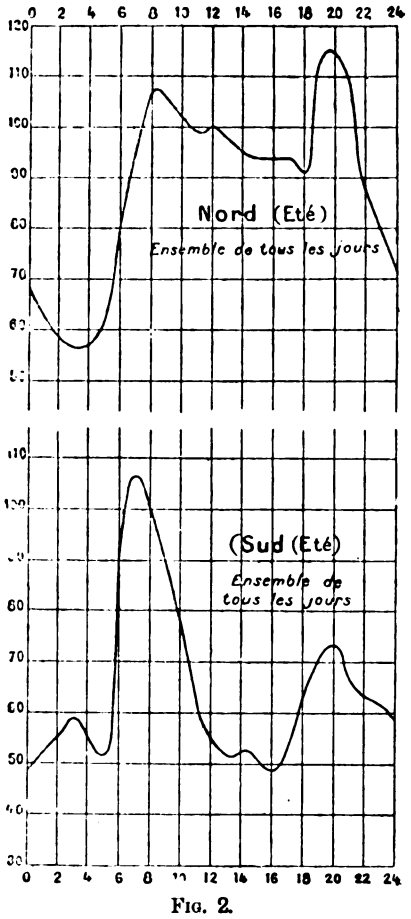

FIG. 2.

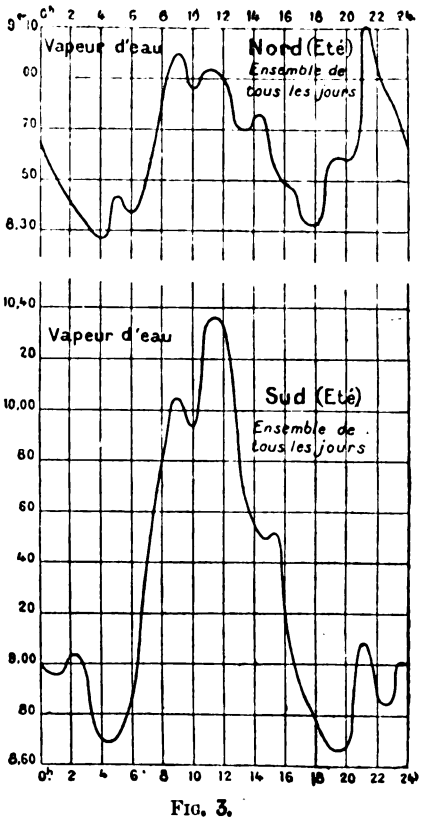

FIG. 3.

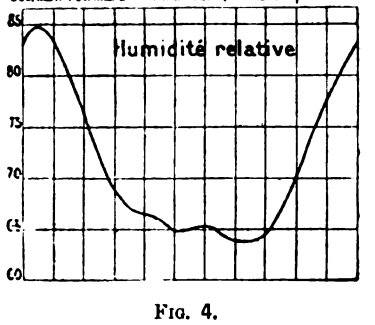

FIG. 4.

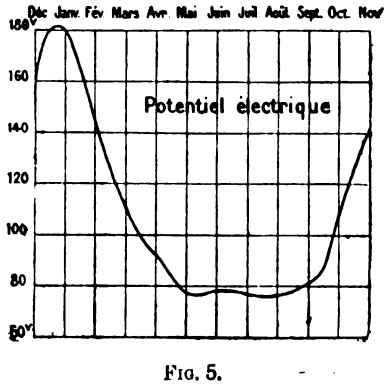

FIG. 5.

Such are the principal facts brought to light at the Lyons Observatory. They seem to imply the existence of a close connection between the variations (and their causes) in the case of the three above-mentioned physical phenomena. It would be very interesting to know if the investigation of the observations made at the other French electrical observatories lead to similar results.

* *Comptes Rendus*, Vol. CXII., No. 26.

† For us the weather is calm and the sky clear—(1) if the speed of the wind exceeds at no instant during the day 2·5 metres per second, (calm or gentle breeze); (2) if out of the 13 daily observations of nebulosity, one at least gives a value equal to ·1.

The Electrician.

ublished every Friday, Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co" All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

'THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements should be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL PREPAID ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1891 Edition, published on the 23rd February, 1891, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with well-written Biographical Notices of leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1891 should be ordered at once. Price 5s., post free 5s. 9d. Abroad postage extra. Prospectuses free.

ELECTRICAL BOOKS AND PUBLICATIONS

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. Vol. I. Price 7s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Vol. I. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

Several Further Volumes in Active Preparation.

NOW READY, IN TWO VOLUMES.

"THE ELECTRICIAN" PRIMERS.

Fully Illustrated.

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra

Volume XXVI. of "THE ELECTRICIAN," price 12/6; post free, 13/6.

ALSO NOW READY.

Cases for bining Volume XXVI., price 2/0, post free, 2/3.

THE TRANSFER OF ENERGY.

The discussion between Mr. SPRAGUE and Prof. THOMPSON, as to the way in which energy is conveyed by the agency of electric currents, has now come to a close, and our readers have had the opportunity of comparing the different arguments which have been advanced. We could hardly have found two more fitting champions for maintaining the rival views which these two writers have upheld, but from the nature of the case Mr. SPRAGUE has been at a great disadvantage. Prof. THOMPSON has, with admirable skill, put into a simple form an already recognised theory, the latest development of ideas which have absorbed the attention of the ablest electricians for years; but Mr. SPRAGUE has had to generate all his arguments for himself, starting from the hypothesis that the energy of an electric current is conveyed along the conductor. The theory that the energy is conveyed along the wire has the merit of simplicity. It has been tacitly accepted by the great majority of electricians ever since it has been known that the electric current is a factor of energy, and many of our readers have, to our own knowledge, been greatly interested in Mr. SPRAGUE's defence of this view against what must be owned to be a complicated theory. We may agree with Mr. SPRAGUE that our object should be "to find out what Nature does, not to invent mere imaginary schemes about her works," and, although we undoubtedly side with Prof. THOMPSON's views, there is no doubt much which appears, at first sight, highly artificial in the elaborate structure of lines of electric and magnetic force and induction, complicated still further, as it is, by the more recently

Digitized by Google

discovered lines of energy-flow. But however desirable it may be to simplify our conceptions of natural processes, we cannot expect to do so all at once. The aim of science is not to find out what is simple, but what is true. The electro-magnetic theory is certainly not simple, but it has much to recommend it; while the idea that energy is conveyed along wires really had its origin, not in any definite theory, but in the fact that the wire was the only tangible thing about an electric current, and the energy was assumed to be connected with it simply because there was nothing else with which it could be associated.

Mr. SPRAGUE has supported an old idea rather than an old theory. The orthodox views advocated by Prof. THOMPSON are of comparatively recent date, but up to the present they form the only theory which has ever been advanced to account for the facts; for, although the notion that the current conveys the energy is very generally entertained, Mr. SPRAGUE is, we believe, the first to support it by argument. Indeed, the idea that energy is located at all, and that, when it changes its position, it must move along a definite path, is quite a new one. The law of the conservation of energy implies that energy cannot disappear from one place without appearing in equal quantity somewhere else; but, although this fact has been long accepted, it is only within the last few years that the idea of the transference of energy has been developed, or that anyone has attempted to trace out the actual path along which energy flows when it moves from place to place. The idea of an energy current is of more recent date than the electro-magnetic theory, and is not to be found explicitly stated anywhere in MAXWELL'S work. We believe that the first time it was applied to electrical theory was in the pages of *The Electrician*, by Mr. OLIVER HEAVISIDE, to whom so much of the extension of MAXWELL'S theory is due. The idea was also independently developed and brought to the notice of the Royal Society in a Paper by Prof. POYNTING. According to the theory, as developed by these mathematicians, the paths along which the energy flows are sometimes of a very remarkable character, but they are not more so than is the case with the well-known and widely understood lines of force generated by the magnetic action of the current, and there is no reason for supposing that the energy paths should be simpler than these. The view that the energy flows with the current is only simple in appearance. Energy does not flow like an electric current round the circuit continuously, for it flows from the generator to the motor, or other absorber, and does not return. If it is confined to the wire it has a choice of paths before it, one with the current and the other against it, and Mr. SPRAGUE gives no reason for its adopting one path in preference to the other, but assumes that it may choose both. Even supposing that Mr. SPRAGUE'S views are tenable, the explanations he has given of the mode in which energy is conveyed are at least as complex as those of the electro-magnetic theory.

The chief obstacle to be overcome by the orthodox theory of to-day before it gains general acceptance is the difficulty people have in believing that large forces can be transmitted without the aid of rigid material connections. Mr. SPRAGUE expresses this view when he asks, "Does any one in his senses argue that, when a mechanical motor transmits energy by means of shafting or belts, the energy is really transmitted by some imaginary medium, and that the shaft and the belt are merely waste-pipes to get rid of some hypothetically superfluous energy which chokes the medium?" This question must be answered in the negative, but the case here considered is very unlike the transmission of energy from a dynamo by means of a pair of leads, although Mr. SPRAGUE appears to consider them identical. Supposing the dynamo to give an electromotive force of several thousand volts, many horse-power could be transmitted great distances by means of wires so thin as to be hardly visible. In such a case we could hardly imagine that anyone would suppose the energy is transmitted along the wire.

When the currents are alternating it is impossible to explain the transfer of energy from a primary to a secondary coil, except on one of two hypotheses. Either the energy must travel across the intervening space, or, by a sort of process of action at a distance, it must be capable of disappearing from one circuit and reappearing at the same instant in the other. Mr. SPRAGUE does not advance the latter hypothesis, and he virtually admits that energy can exist in the medium when, in explaining the diagram given on page 608 of the last volume of *The Electrician*, he alludes to the lines *e e* as representing "energy stored in producing stresses, chiefly *outside* the conductor." It is true that he does not say where the energy is stored, but it can only be logically located in the places where the stresses occur. The amount of energy thus stored, and the flow of energy in the medium necessary to supply it, becomes a very large fraction of the whole energy when alternate currents and transformers are in question; and it is of no use to leave out the consideration of such currents because, as Mr. SPRAGUE urges, steady currents are the simplest to consider. If it is once admitted that a large fraction of the energy corresponding with an alternating current is located in the medium, Mr. SPRAGUE'S contention must be abandoned.

Much of the obscurity of the subject arises from the difficulty of understanding the true function of the conducting circuit. To say that the wire acts merely as a guide to direct the flow of energy in the medium, and that the heating which occurs is only the waste energy caused by the method of constraint, does not make the matter, already rather complicated, any easier to understand. Ohm's law and the laws of electrolysis are so simple that it seems a retrograde movement to abandon the idea that an actual flow takes place in the wire, and, if the actions going on in the medium are so important, it is not easy to see, for instance, why the resistance of a parallel combination of conductors is not altered by bending the wires, or separating them. The hydraulic analogy, when closely examined, is, however, continually at fault, and Mr. SPRAGUE himself is dissatisfied with it, since he voluntarily abandons the words resistance and current, and proposes to substitute ohmage and amperage for them. We generally look upon the current in a solenoid as the *cause* of the magnetic force it exerts, but this idea has really nothing to support it. The fact that the strength of a current is a factor of its energy is no more a proof that the energy is held in the wire, than the indications of a pressure gauge on a boiler show that the energy of the steam is similarly located. A current is defined and is nearly always measured by the magnetic force found *outside* the wire. With the single exception of the heating effect, a current in a wire can only be detected by its external effects, and it is just as correct to argue that the magnetic condition of the medium should be regarded as the *cause* of the current as its *effect*. The path of the current is quite clear when we have simple circuits of good conducting material, but with imperfect insulation the course of the electricity may be far more complex than the supposed path of the energy current; and, indeed, cases exist in which the flow of energy takes place in a very simple manner indeed. When electrical energy is conveyed by a current through concentric mains, theory shows that the flow of energy is confined to the insulating material between the inner and outer conducting tubes, and that it passes from the

Digitized by Google

source of energy to where the work has to be done. Here the path of the energy current is very simple, and the hydraulic analogy can be applied to it with even greater truth than to the flow of current in the tubes. The heating of the metal conductors is due to a kind of frictional waste occurring at the inner and outer surfaces confining the energy current, just as the frictional resistance to the flow of water in a pipe is due to surface action.

Until the electro-magnetic theory is further advanced it is unlikely that a discussion, such as Mr. SPRAGUE and Prof. THOMPSON have carried on, will alter the views of anyone already strongly biased upon the points at issue. The most valuable result of such a controversy is due to the fact that the opposing views are brought out with greater clearness than before. Prof. THOMPSON has freely admitted that there is no experimental evidence in favour of the orthodox theory when the currents flowing are steady, while, on the other hand, Mr. SPRAGUE has made it clear that he does not contend that the energy current is entirely confined to the wire, for he admits that the energy traverses the medium between the primary and secondary circuits of an induction coil. The theory explained by Prof. THOMPSON, however complex it may be, accounts exactly for the phenomena referred to, while the apparent simplicity of Mr. SPRAGUE'S views is mainly due to their purely descriptive nature. Prof. THOMPSON has gracefully allowed his opponent the last word in the controversy, and, in view of the fact that Mr. SPRAGUE excludes alternate current phenomena from argument, it is clear that further discussion can serve no useful purpose.

REVIEWS.

A Manual of Electro-Therapeutics. By ARTHUR HARRIES, M.D., and H. NEWMAN LAWRENCE, M.I.E.E. No. III.—The *Nursing Record* Series. (London: Sampson Low.) 1891.

We have always strongly sympathised with the genuine effort which the present authors have made to place "electro-therapeutics" on so sound a basis that it might rank as a department of medical science. They have most conscientiously placed themselves under a restriction which must occasionally hinder their practice, by making it a rule that they will only treat patients under independent medical advice. They have been most assiduous in the direction of the Institute of Medical Electricity, as well as in the production of numerous papers and handbooks, and considerable success has, we believe, attended their efforts. In carefully avoiding everything that can, by the most careless observer, be confounded with the shameless quacks who drive such a good trade in so-called electropathic appliances, the authors of the book before us have endeavoured to explain "in an easily assimilable form" the elementary facts of electrical science, and "the physiological and pathological phenomena which depend for their production upon the application of various forms of electricity, and the methods by which it has hitherto been possible to employ this agent in the treatment of pathological conditions." After a first chapter or "lesson" on electrical energy, different kinds of batteries are discussed, but we are surprised to find no mention whatever of the excellent "dry cells" which are now on the market, and which we should have thought were admirably adapted for the occasional work required for medical purposes. The next lesson—on electromotive force, current, and resistance—is greatly indebted to the hydraulic analogy, which, with no disrespect to the "nurses and students," to whom the handbook is addressed, is no doubt better suited for them than the more intricate hypotheses which have recently been argued in our columns. This chapter is marred by one sentence introducing an expression which somewhat disfigures the rest of the book:—"The quantity of electricity flowing through or past any point in a conductor during any given time is designated the current strength, or, more shortly, 'the current.' As however, we desire to avoid all risk of confusion regarding the terms involved, we prefer to call this factor in the current flow *current-strength*." The authors go on to use the signs C-s and c-s throughout the remaining chapters where they simply mean current in amperes or milliamperes. It is difficult to understand why some writers feel that the mere word current is ambiguous, and attempt to make things clearer by speaking of the intensity of a current or current-strength. Quoting at random from later pages we have, "a c-s of 15 milliamperes has to be administered," "cells in parallel give the maximum c-s," "an E.M.F. of seven volts, and C-s of 500 m.a. passed." By m.a. the authors mean milliamperes. We fail to see why this expression "current-strength" should be required in discussing electro-therapeutics, when engineers and electricians generally can get on with the single word "current," and with a simple symbol to represent it. We admit that current has two properties, strength and direction, and that it is sometimes convenient to speak of the strength of a current, but if the strength of a current is said to be greater at one time than at another, it simply means that the current is greater. We object to this expression, because it suggests that a current has an existence apart from its strength. The authors, in giving a short glossary at the end of this chapter, revert to exact and simple language viz., "Current. The quantity of electricity flowing through or past any point in a conductor during any given time." We have dwelt on this tautology at some length, not because it is uncommon, but for the very opposite reason.

The fourth "lesson" proceeds to consider some of the medical applications, and, as examples of the properties of continuous currents, they discuss Cataphoresis, Electrolysis, and Catalysis. We have accepted the first of these expressions, and have from time to time used the title "cataphoric medication" for several Notes on the subject. The authors' views are by no means accepted among physiologists, and we have not noticed that they point out that osmosis does not follow the same laws in the living tissue as in the dead. On the other hand, the authors have done much to establish this as a useful method of conveying drugs through the skin. Of electrolysis we need say nothing, but the treatment of catalysis as a distinct class of phenomena is rather strange. We have always considered catalysis as a permissive or directive action by which the presence of a substance determines a chemical combination, apparently by its mere presence, and with little or no expenditure of energy. It has, perhaps, become a convenient resting place for a residuum of unclassified phenomena, and in organic chemistry and biology, catalysis is used as a mere name for the action of ferments. But the authors include by it "both cataphoresis and electrolysis;" "dilatation of blood vessels;" "increased power of absorption conferred upon the tissues;" "promotion of osmosis, and following upon these two processes, increase of tissue bulk." A most comprehensive class, but one which is so wide as to be utterly vague and useless, and not warranted by the reasons assigned.

We have so greatly exceeded our usual limits that we must pass briefly over the latter chapters. The induction coil and magneto machines are alluded to, and the importance of measuring the "dosage of electricity" is very properly insisted upon. Various kinds of electrodes and other instruments are described, and a chapter is devoted to the physiological action of currents, but no allusion is made to the accepted phenomena of electrotonus. A chapter on skin resistance, a matter of some importance, since it determines the "dosage," ends with a table of observed resistances, but these varying from 620 ohms to 2,170, with no relation between the resistance and the path of the current, convey no information to the student, who may discover by computation that 1,200 ohms is the average, but as the conditions of "soakage" and contact are not given, this teaches him nothing. The tenth lesson deals very usefully with methods of application, and is followed by a number of practical hints about electrical applications and the management of apparatus.

The aim of the handbook is excellent, much of the matter is very useful, and the subject is one which we greatly desire

Digitized by Google

to see developed. For these reasons we have dealt with it at some length, and hope that it will be carefully revised or will form the nucleus for the first comprehensive work on the subject, and one which may dispel the scepticism of the medical profession. The manual contains numerous illustrations. We can only suppose that the authors intended them to be re-drawn, and by some blunder their sketches were reproduced in fac-simile.

A First Course in Machine Drawing (Tracing). Part II. (Electrical Engineering). By GEO. HALLIDAY, Instructor of Mechanical Drawing and Lecturer on Mechanism at the City and Guilds of London Technical College, Finsbury. (London: E. and F. N. Spon). 1891.

Tracing is altogether ignored by many drawing masters, who endeavour to teach their pupils, at once, to make a drawing, as this is considered to be the ultimate object of a draughtsman. Such drawing masters have in many cases never set foot in an engineer's drawing office, and disregard the course of training usually followed by the engineer's draughtsman. The idea of beginning with tracing is as thoroughly practical as are the conditions of examination at Finsbury, to which we alluded last week. As a rule, the draughtsman begins to trace when a lad, and continues to trace, often for year after year, without ever a chance of trying pencil or pen upon drawing paper. While thus engaged, the subjects of his work, the conventions by which it is expressed, the style, and more than this, some intuition of the elements of design, cannot but sink into his mind. Besides this, he learns to do properly various matters which are essential to good drawing, *e.g.*, mixing inks, making good joins and even lines. It is obvious that after learning the mere mechanical work of tracing, the student will be much less likely to ruin his first drawing in the inking in.

The conventional rules of mechanical drawing vary very largely in different drawing offices, and we are not sure whether it is advisable to teach students that there is only one correct style. The only detail that we need refer to here is the uniform thickness of line which is insisted on as being of primary importance. Where greater clearness can be obtained by the occasional use of a thick line, either *as* a line or as a shade line, we do not think that any considerations of convention should forbid it, even in a tracing.

Dynamo Construction. A Practical Handbook for the Use of Engineer-Constructors and Electricians-in-Charge. By JOHN URQUHART. (London: Crosby Lockwood and Son. 1891.)

This book is a companion to the works by the same author on Electric Light and Electric Light Fittings. He offers it to "ordinary engineers and mechanics," and to "engineering students." If by "ordinary" engineers the author does not include electrical engineers, we think that he attempts too much. The history and development might be entirely omitted, just as modern text-books on steam-engine construction omit descriptions of the work of Newcomen and Stephenson. Of course, a book for beginners should begin at the beginning; but this beginning need not be of an historical kind. We are inclined to doubt whether it is necessary to go back to the "simplest conception of a dynamo." That is a matter of elementary electrical science. Twelve or fifteen years ago, it was still customary for pupils to go straight from school or college to the workshop, and there they learned the construction of steam-engines in the shops while they gradually picked up a knowledge of thermodynamics from text-books. Now it is more usual to learn the elements of physics and of the theory of the steam-engine at a technical college before apprenticeship. At all events, the study of electrical science and of dynamo construction are two totally distinct matters, and we should prefer to let the latter follow the former. An elementary account of the principles of the dynamo, such as the one before us, may be useful to "ordinary engineers" who have no intention of devoting much time to the subject. But as a text-book for "engineering students," the present work is insufficient. Far too many "typical dynamos" are described, and many of those which are included under this title are neither typical nor sufficiently worthy of notice. The causes of sparking, which should be clearly understood by all those who have to do with dynamos, are not clearly expressed, and among some otherwise useful "operative notes," it is suggested that "in starting a dynamo the brushes should be set in the most advantageous position. This will generally coincide with the line of least sparking." What the benefits may be of the "most advantageous position" which can compare with the importance of "least sparking" we are unable to guess. The Westinghouse and Ferranti dynamos are well described and many of the illustrations are new.

ELECTRIC AND MAGNETIC THEORIES.

BY JOHN T. SPRAGUE.

Prof. Silvanus P. Thompson in his last reply commences by admitting that there is no evidence, during the steady flow of currents, that energy is transferred across the medium; but he goes on to say neither is there any evidence that it is transferred along the wire. Now, that I must dispute. We have abundant evidence. We have the current, which needs energy to support it, and which is clearly originated in the source, being related to the chemical action when that source is a battery; we have the energy issuing from the wire, and if the circuit does no external work, we can trace the whole energy of the source present as heat in the conductor. When known actions occur in the medium, the current and energy in the circuit are proportionally diminished. Now, that is evidence, it is fact; the energy is in the wire.

But now examine the medium. I am blamed for refusing the evidence of the Hertz experiments. I have not done so. I only refused to bring confusion into this argument by dealing with very complicated actions, which no one even pretends to fully understand, while there was plenty of clear evidence available. But now I am going to claim that the Hertz experiments prove nothing of what it is asserted they do, and that, so far as they go, they prove my case. Prof. Thompson foresees my point: it is that the Hertz experiments, like all others upon induction, relate only to the variable period. The evidence that they give as to constant current is, that the medium, the space is wholly indifferent, that by no means can we trace the least action in space, except when current is varying in the conductor. Now, surely I may make the same claim as Prof. Thompson began by; I may say, if it is clear that energy is *not* transmitted across the medium during the full action of the source, then we have the right to say it is *not* transmitted from the source at any time.

§ 2. And that is what I do say, and consider that I have proved, and Prof. Thompson has done his best to prove for me, viz., that energy does not traverse space from the source "radiant in precisely the same sense as light is radiant," but that it is propagated only from the conductor by medium of the lines of electric and magnetic induction, set up only by the current in the conductor. As to this, he says, "unfortunately, it can be shown that it moves at right angles to them." That is a mere assertion which I defy him to prove. It is known that an action occurs at right angles, and that energy is propagated there; but what is the order of sequence? We all know that electric and magnetic action are interlinked, that one cannot be set up without the other accompanying it, to a degree dependent upon the nature of the matter present. When the magnetic lines are forming in his Fig. 1 of the two coils, the production of an electric field in planes at right angles to them is an inevitable incident; because his secondary coil occupies those planes, a momentary electric current is the inevitable accompaniment of the setting up of the magnetic lines and field But that is not lateral transfer of energy, even from the primary conductor; it is a lateral action of the newly forming magnetic lines, and the energy "swirls round" as required by the position of the conductors and the various lines of force.

But all these lines can be put in evidence; their stresses can be made visible. If the hypothetical lines cannot be so shown, I take it that the reason is the same as that which prevented the Spanish fleet from being visible in the old opera. I wholly decline to accept Prof. Thompson's assertion that "the energy paths in the medium are, after all, just as real entities as the

Digitized by Google

magnetic lines are, though not so familiar to us." No one has the right to make such a statement without some evidence.

§ 3. I have no doubt that Mr. Heaviside is correct as to the result of this line of persistent assertion by the teaching powers. There can be no doubt that the growing generation of students will accept as truth the mere guesses of their teachers determinately asserted as proved truths; then they will go "by faith, having taken it when young. So it will be with the modern view of the ether as the medium through which energy is being sent when a wire supports a current. Only train up the young to believe this, and they will afterwards look upon the notion of its going through the wire as perfectly absurd, and will wonder how anyone could have believed it." Doubtless, they will believe it just as for a long period the scientific men believed in Phlogiston, and then some day they will learn that what they thought was knowledge was nothing but a delusion. That is what I am trying to prevent when I demand evidence of these assertions.

§ 4. Now let us examine for a moment the assertion that "electric energy is radiant in precisely the same sense that light is radiant." Now light is radiant in the sense that it issues as *radii* from a centre. Will Prof. Thompson, or anyone, show us one single instance of electric energy doing this. We all know that in the apparently similar case of a charged sphere, the seemingly radial lines exist only if a uniform opposed surface surrounds the sphere; if we bring that second surface into a small surface near the sphere, the radiance is converted into closed curves between the two. Is there any instance of a really radiant energy being so affected? Does light ever "swirl round" in this way?

Now I am going to contend that the Hertz experiments, examined apart from the fog of assertion which surrounds them, prove that electric energy is not radiant, like light. I say nothing about undulations and nodal points, but I do say that the line of propagation is not radiant, not lines or rays like those of light, but simply the expanding surface of the curves of force uniting the two surfaces of the inductors; that, as in all other electric cases, the origin is dual, and the line is a closed curve growing out into space, just as those of an electro-magnet do. The action induced in the resonator is due to the resonator becoming a part of these curves, just as iron becomes a magnet when occupying a line of magnetic force. Dr. Lodge's metal surface screens the space behind it by taking up the whole of the electric lines, just as iron screens the space behind it from magnetic action. That is very different from being radiant, in the sense that light issuing from a single source is radiant.

§ 5. It is a pity that my suggested experiments do not commend themselves to Prof. Thompson. He says, "a total reflector of energy is yet undiscovered." I thought Dr. Lodge had shown recently that the thinnest film of a conductor entirely shields a so-called resonator from the Hertz effect. Surely that means that energy is not propagated across the screen; but never mind the total reflector. Will Prof. Thompson assert that any screen or reflector whatever will produce the shadow of an influence on the current or the heat of a wire (unless it affects the resistance, by confining or dissipating heat). If the energy enters the wire from the outside, some effect ought to be traceable; it is easy enough to produce an effect by changes in a distant part of the conductor. I must say I am disappointed. I did hope to get some notion as to what the new theory really is. I did not expect it to be proved, but I expected it to be defined, and some notion given as to its operation. As it is, we are just where we were at first. We are expected to believe that energy issues radiant from a source just as light does, and then swirls round and begins to build up a scaffolding of equipotential lines, crystallising upon the conductor, which conducts nothing, not even an impulse, serves no purpose but that of a waste pipe, which light does not require, and generally that this energy swirls about without any guiding force, and yet always finds its way to this conductor. And all this structure of hypothesis and assertion is based upon the imaginary properties of an ether of which our only real knowledge is the single fact that light traverses space, and our minds cannot conceive how it does so unless there is something there to transmit it.

NOTES ON PERMANENT MAGNETS.—II.*

BY PROF. SILVANUS P. THOMPSON, F.R.S.

Maximum Values of Permanent Magnetism.—In the following table are given some of the values of maximum magnetisation retained by actual steel magnets, magnetised by usual processes, and of the "specific magnetisation" σ, or magnetic moment per gramme:—

Observer and Material.	Residual I.	Residual B.	σ.
Weber, common steel magnet	314	3947	40
Von Waltenhofen, Tungsten steel, glass hard	369	4638	47
Schneebeli, sewing-needles 2·5 to 6·6 cm. long, 0·06cm. thick	557 to 671	7001 to 8435	71·4 to 86
Schneebeli, knitting-needles, 19·8 to 21 cm. long, 0·083 to 0·175cm. thick	765 to 832	9626 to 10458	98 to 107
Hopkinson, Tungsten steel, oil-hardened	687	8643	88
" " " very hard	542	6818	70
Ewing, steel wire, glass hard	541	6800	69
" pianoforte wire, glass hard	747	9600	98
Perry, Jowitt's steel	1003	12600	129
Preece, Wall's steel	120	1519	15·5
" Ashforth's steel	143·5	1704	17·3
" Saunderson's steel	114·2	1435	14·6
" Jowitt's steel	109·6	1503	15·3
" Vickers's steel	93·4	1174	12·
" Crewe "rivet steel"	14·8	186·6	1·9
" Crewe "spring steel"	110·5	1391	14·2
" Clemandot steel (compressed and tempered)	170	2264	23·2
" Clemandot steel (compressed but untempered)	106·1	1333	13·6
" Marchal steel	202·2	2540	26·
" Allevard steel (mercury hardened)	104·6	1315	13·4
" " " (water hardened)	132·1	1660	16·9
Gray, magnet steel, glass-hard	520	6536	66
Evershed, Wall's and Jowitt's steels (mean).	318 to 398	4000 to 5000	41 to 51
Brown, magnet steel, glass-hard	477 to 556	6000 to 7000	61 to 72

It is important to note, with respect to the above table, that there is a wide difference in the relative dimensions of the samples used by different observers. The ratio of length to diameter makes, as is known, a great difference to the temporary magnetisation of a specimen; and in the case of permanent magnetisation the differences are even more marked. In Schneebeli's experiments the length used was from 100 to 800 diameters. In Ewing's about 200. Hopkinson's results were with practically endless bars. Perry employed a horseshoe form, closed with an armature of soft iron. Gray† used square bars about 60 diameters long. Brown‡ used cylinders from 33 to 37 diameters; whilst Preece§ used short, square bars, 10 centimetres in length and 1 centimetre in the side. The results given by Preece are the means of several samples of each sort, not the actual best obtained with each. For example, the mean residual **B** for Marchal's steel is given as 2,540, but the best magnet of this sort showed 2,835.

The numbers given in the first column of figures of the last table are the values of the residual *magnetic moment per centimetre cube* of the substance (in C.G.S. measure), and are obtained from the residual **B** by dividing by 4π. Many Continental writers on this subject prefer to give the values in terms of the *magnetic moment per gramme*, a quantity which is also called the *specific magnetisation* of the material. If the density of the specimen is known, the specific magnetisation σ can be calculated from the residual **I** by dividing by the density. For example, taking Gray's figure of 9,804 for the residual **B**, dividing by 4π gives residual **I**, and dividing by 7·8 (which we assume as the density of the steel) gives 100 for the specific magnetisation. In all the preceding table the only samples showing values over 100 for the specific magnetisation are those

Digitized by Google

obtained by Schneebeli and by Perry. Preece's results for *short* magnets of 10 diameters show specific magnetisations varying from 2 (Crewe "rivet steel") to 26 (Marchal steel).

Ewing found, using enormous magnetising forces which pushed the temporary value of B for Lowmoor and Swedish iron to over 30,000, that the residual values of B were only 510 and 500 respectively, whilst cast iron showed only 400. This means residual I of 40, 39, and 32 respectively, and specific magnetisation of between 6 and 5 only. Du Bois, also using abnormally strong fields, found the residual specific magnetisation for electrolytically deposited nickel 10·6, and for electrolytic iron from 70 to 106.

Influence of Temper and Grain.—In the preparation of permanent magnets, temper is almost as important a consideration as the chemical composition of the material. Most makers have their own favourite method of hardening and tempering, and few can or will give exact particulars. Neither is it possible to give a universal rule as to the best process to follow: for the process of tempering which is best for one brand of steel is different from that which is best for another brand. Tempering does not mean the process of hardening, though careless writers sometimes confuse their meaning by using the term in this erroneous sense. Tempering means the process of letting the steel down to a softer state by a partial re-heating subsequently to the hardening. Moreover, as will be seen, the temper which is best for *short* magnets is quite different from that which is best for *long* magnets and horse-shoe forms. There is, however, no doubt that it is eminently desirable to secure a fine even uniform grain, since any lack of homogeneity tends to reduce the quality of the magnet. An unskilful smith in forging a magnet will spoil its structure by working it too much and unequally. It is commonly supposed that the harder a piece of steel is, the greater retentive power will it exhibit. But under this term two separate qualities must be distinguished. Some steels will show, after magnetisation, a large residual magnetisation, which, however, decays as weeks and months pass away. Some other qualities of steel will exhibit a lesser remanence, but will conserve much longer what they have thus retained. The question of constancy of retention will be separately considered hereafter.

There are several ways of hardening steel. One is by suddenly cooling it from a bright red heat; another is by subjecting it to enormous pressure by hydraulic machinery whilst it slowly cools down. In the former method, which is the usual one, the outer crust cools suddenly, whilst the inner portion is still plastic, and probably compresses it by natural contraction. In the latter method the hardening, though less extreme, is more uniform throughout. It is also possible to harden wires by mere longitudinal traction, as is well known. But this is not used in the manufacture of magnets. If thin rods of steel are heated to a brilliant redness, or even almost to whiteness, and then suddenly plunged into water, oil, or, best of all, mercury, they become intensely hard and brittle, and, indeed, are frequently split in the process. This state is known as *glass-hard*. If the glass-hard steel is then re-heated to near a very dull red heat, for a short time, it softens somewhat, and acquires a pale yellowish tint on the surface, this temper being technically known as *straw-colour*. If it is still further let down, by continuing the re-heating, it becomes *blue* in tint, this temper being used for steel springs, steel pens, and other purposes requiring flexibility. If the re-heating is carried still further the steel becomes soft, being annealed by the continued exposure to a dull red heat. Now, if it were true that the hardest magnets were the best, it is clear that none ought to be tempered down, but all should be left glass-hard, which is not found in practice to be by any means the best course.

Galvanic Estimation of Hardness.—The specification of the degree of hardness by tint is extremely vague. Happily it has been found that steel possesses another and more measurable quality which exists in almost exact proportion to the hardness of the specimen—namely, its electric resistance. Barus,* who examined this fact, and Fromme†, have shown that this relation is very close; and Strouhal and Barus‡ have used this property to specify the hardness of various bars subjected to magnetisation. As an example, they give the following values for a sample of steel:—

State.	Specific resistance in microhms per centimetre cube.
Glass-hard	45·7
Bright straw tint	26·9
Straw tint	26·3
Blue tint	20·5
Bright blue tint	18·4
Soft	15·9

Influence of Form on the Temper that will give a Maximum of Permanent Magnetism.—In all comparisons between hardness and retentiveness, account must be taken of the form of the magnet, for, as already mentioned, short magnets and long magnets possess different properties. In almost all the experiments made on this matter, the steel rods or wires used have been of square or circular section, usually the latter. Consequently, the most convenient way of describing the form of a straight magnet is to state how many times its length is greater than its diameter. In some of Ewing's experiments on soft iron, rods were used varying in length from 50 to 200 diameters, and the results showed that even though the temporary magnetisation was forced up to about the same degree for all, yet the longer rods showed a greater remanence than the short ones. It will be convenient to use the symbol δ for the ratio of length to diameter.

Some important researches were made by Cheesman,* on the effect of hardening by stretching on magnets of different dimensions. Using an English "silver steel" wire (of Messrs. Cook's), 1·28 millims. in diameter and 90 millims. long (*i.e.*, $\delta = 70$) magnetised by contact with a large electro-magnet, he found the result of hardening by stretching to *decrease* the amount of permanent magnetism which the magnet would receive. The magnetising was repeated after each stretching.

—	Stretching weight in kilogrammes.	Specific magnetisation.
Steel, soft	0	78·1
Harder	30	77·3
Still harder	60	70·8
Still harder	70	63·7
(Wire broke)	75	55·6

In another series of experiments the length was varied.

Dimension-ratio. δ	Specific Magnetisation.	
	Soft.	Hard.
22·5	16·4	18·0
40·4	48·0	48·4
58·6	75·6	60·4

From these and numerous other experiments Cheesman concluded that for short magnets hardening the steel increased the retentiveness, whilst for long magnets hardening decreased it. He fixed upon 41 diameters as the critical value of δ for this kind of steel.

Messrs. Strouhal and Barus made a much more searching investigation of the matter, including the question of tempering. They used various sorts of iron and steel; but the results now quoted relate to magnets made of "silver-steel" wire, of Messrs. Cook's, of Sheffield, of diameter 1·48 millimetres, and density 7·7. Of this steel five magnets were prepared, varying from 10 diameters to 50 in length. These were first made glass-hard by sudden cooling in water and then magnetised. They were then subjected to the following processes, their magnetism, after being remagnetised in a coil supplied with current of 80 amperes, from a dynamo machine, being observed (by a magnetometer) from time to time:—Heated (*a*) in steam at 100°C. for one hour, two, three, four hours; (*b*) in anilin vapour at 185deg. for 20 minutes, one hour, two, four, six hours; (*c*) in melting tin at 240deg.; (*d*) in melting lead at 330deg.; (*e*) in melting

Digitized by Google

zinc at 420deg. (this latter temperature is a dull red heat); (*f*) to red heat so as to reduce the steel to complete softness, the magnet being laid in lime in a piece of gas-tubing, and thereafter slowly cooled down. The results, which are of the highest importance, are given in the following table :—

Course of Tempering.	Hardness.	Specific Magnetisations.					
		$\delta =$	9·9	20·3	29·2	40·5	49·8
Glass-hard	43·8	...	24·8	41·0	47·2	50·8	52·5
1 hour in steam at 100°	38·6	...	23·3	39·2	45·2	48·7	50·4
3 hours „ „	36·5	...	23·4	38·6	44·5	47·7	49·3
6 „ „ „	35·1	...	23·3	38·6	44·3	47·4	49·1
10 „ „ „	34·3	...	23·3	38·3	44·2	47·4	48·9
20 min. in anilin vapour at 185°	29·0	...	21·0	38·9	46·0	50·3	52·3
1 hour „ „	27·5	...	21·3	40·2	48·1	52·9	55·1
3 hours „ „	25·6	...	21·6	42·7	52·2	57·7	60·2
7 „ „	24·2	...	21·8	45·5	56·9	63·5	66·8
13 „ „ „	22·9	...	20·9	46·2	59·7	68·1	71·8
10 min. in molten tin at 240°...	22·2	...	20·4	46·7	61·0	70·2	74·3
1 „ „ lead at 330°	19·0	...	19·0	46·7	68·0	83·7	90·0
1 hour „ zinc „ 420°	16·2	...	14·4	40·1	72·6	93·9	103·9
Annealed	14·9	...	4·3	10·2	18·7	29·8	42·4

This table is but one of a large number, all tending to the same general result. The figures given under the column of "Hardness" are the specific electric resistances in microhms. It is interesting to observe how with short magnets the specific magnetisation decreases, then shows a tendency to increase, then decreases again, as the softening proceeds. Another point is that in every case heating in steam slightly reduces the magnetisation that a magnet will retain; but that after some five or six hours a practically constant value is attained.

A very large number of observations with wire of the same sorts were made by these experimenters, with practically identical results. They endeavoured to fix (on the galvanic scale) the actual hardness and magnetic value of their steel when tempered to the tints recognised by workmen, with the following results :—

State of Temper.	Hardness.	Mean Specific Magnetisation.					
		$\delta =$	10	20	30	40	50
Glass-hard	45·7	...	23·5	37·6	43·6	46·5	48·3
Straw-tint	26·3	...	21·4	40·2	49·4	53·8	56·5
Blue-tint	20·5	...	19·3	45·8	67·0	80·4	87·3
Annealed Soft	15·9	...	4·3	11·2	20·5	31·8	44·6

These results agree with those obtained by Ruths,* who found (using another sort of steel) that for short magnets ($\delta = 20$), the specific magnetism fell from glass-hard, 51, to 28·4 when tempered blue, whilst for long magnets ($\delta = 70$) the specific magnetisation which was 68·7 for the glass-hard state, increased to 92 when tempered blue.

Fixidity of Magnetism.—The researches summarised above, important as they are, do not, however, answer the question—what state of temper produces a magnetisation of the greatest constancy in amount? This precious quality, to which Scoresby † gave the name "fixidity," cannot even be predetermined by an inspection of the values of the coercive force, such as have been given by Hopkinson, because these are themselves subject to change with time. Scoresby suggested a method of examining the change of magnetism which was brought about by placing the magnet gently down upon the similar poles of another and more powerful one. He took as the measure of the goodness of a magnet (for the purpose of compass needles, &c.) the product of its original strength into its reduced strength after such treatment. By this method Scoresby (whose magnets were 6in. long, 0·5in. broad, and from 0·5in. to 0·0625in. thick) found the percentage of reduction to be least in cast steel when hard, and to be less when tempered blue throughout than when tempered at the extremities only. Kater ‡ found that for compass needles of *thin* steel it was of advantage to temper down soft the middles of the needles, leaving the ends only hard.

THE FRANKFORT EXHIBITION.—V.

(FROM OUR SPECIAL CORRESPONDENT).

The Exhibition is now to all intents and purposes complete. The steam engines and dynamos are in position, the numerous workshops are in operation, and the electric launches are at last running. The 165ft. electric light tower, the various electric transmission of power installations and electric tramways are also in working order. The total number of visitors to the Exhibition up to June 30th was nearly 190,000.

One of the most interesting installations of transmission of power is that connected with the artificial waterfall. Coupled by means of two belts, lying one over the other on the flywheel, to a 100 H.P. tandem engine, by Woolf of the Nuremburg Maschinenban-Aktien-Gesellschaft, are two dynamos transmitting power to two corresponding motors driving two centrifugal pumps. The pumping station is about 100 yards from the driving dynamos in the Machinery Hall, and the work done by the pumps is to deliver about 38 gallons of water per second, to a height of about 10 yards. The centrifugal pumps are by Sulzer Brothers, of Winterthur, in Switzerland; the water pumped by each machine is conveyed in one pipe up to the waterfall, and this union of the streams of water before delivery seems to have the effect of preventing the motors from running quite independently of each other.

One of the dynamos generating the electricity for the use of the motors is an ordinary direct current compound 16-pole machine, by Schuckert, running at 550 revolutions per minute. It is designed to give 38·5 kilowatts, and it drives a corresponding motor coupled direct to one of the pumps.

The other dynamo and its corresponding motor are more novel. The dynamo has an output of 44 kilowatts at 330 revolutions, and the current for the magnet excitation is obtained from accumulators. The machine is of similar construction to the first, but being separately excited it is not provided with a commutator. As the current generated in the armature of a direct current machine is always alternating, when not commutated, the idea here has been to take off two alternating currents from the machine of 90 deg. difference of phase. This has been done by arranging four rings on to the axis of the machine; two of these are connected to the armature coil at opposite extremities of the same diameter; the other two rings are connected in the same way with points on the armature coil at the extremities of a diameter at right angles to the first. The first two rings are joined by two cables to the corresponding rings of the motor, and the second two are also joined to their corresponding motor rings in the same way. The currents of 90 deg. phase difference given to the motor-armature through its rings, at points corresponding to those on the armature of the dynamo from which they were taken, will, if i be the maximum current in each, and if θ is the phase angle of one, give in the ring a current—$i \sin \theta + i \sin (90° + \theta)$, or $i (\sin \theta + \cos \theta)$, or $\sqrt{2}\, i \sin (\theta + 45°)$. This current is in its phase 45 deg. different from each of the alternating currents introduced to the armature and $\sqrt{2}$ times as great as either. In consequence of this current the machine starts automatically. Both the direct current and alternating current motors run singularly smoothly, and up to within a few feet it is nearly impossible to tell whether they are in motion or not, as regards the sound emitted. Before shutting off the current from the motors it is necessary to cut off the connection with the centrifugal pumps; otherwise the latter would let the backflow of water drive them round in the opposite direction.

There is a second dynamo similar in construction to the alternating machine with different phases just mentioned, but it has a commutator in addition to the four rings. A machine of this description can be used for many purposes, as, for instance, in the following cases :—It can be used as ordinary direct current machine, or direct current motor, when current is taken from or sent through the commutator; for a self-exciting alternating current machine from which two currents of 90 deg. phase difference can be taken, the currents of which are independent of each other, and have not necessarily the same maximum strengths, these depending on the resistance of the external circuits; for a machine in which one or both of the above alternating currents can be taken off, and at the

Digitized by Google

same time direct current used from the commutator, both for the magnet excitation and for electric lighting, or other purposes. It can, of course, be used as a transformer from alternating to direct currents, and *vice versa*, and lastly as an alternating current motor.

A machine of this kind is at work in the Palm Garden installation. It is driven by a compound engine of from 50 to 60 H.P., by Ruston, Proctor and Co., of Lincoln, which drives at the same time a dynamo by another firm. The Schuckert dynamo generates about 25 E.H.P., at a low voltage, which, after transformation up to 2,000 volts, is economically transmitted by three cables to the Machinery Hall, a distance of about 1,200 yards, where, by means of a suitable step-down transformer, it drives seven motors similar to the alternating one in the pumping station described above. The transformer in the Palm Garden installation is of 20 kilowatts.

The Telephone Installation, erected by Mix and Genest, of Berlin, connecting the Opera House with a small detached building in the grounds of the Electrical Exhibition, proves a decided attraction. This firm has provided, upon the stage of the Opera House, four specially-constructed transmitters, two to transmit the vocal, and two the instrumental, portion of the performance.

THE ELECTRIC TRANSMISSION OF POWER.*

BY GISBERT KAPP.

The transmission of power, in whatever way it may be effected, is one of the most important problems in applied mechanics. Strictly speaking, it enters into and is, indeed, precedent to the application of power to all industrial operations. The power developed in a Lancashire mill-engine only becomes of value to the spinner or weaver after it has been transmitted to the mules or looms by the agency of ropes, belts, pulleys, and other gear. Without such gear effecting the transmission, the power developed by the local steam-engine would be as useless to the mill owner as the power which may be contained in a waterfall miles away. In either case transmission must precede the application of power, but whilst in the former case the problem of transmission is simple, and has to be attacked rather from the point of view of convenient subdivision, than with particular regard to efficiency (this being naturally high with properly designed gear), in the latter case the problem is of a much more difficult character, and efficiency, combined with moderate capital outlay, small working expenses, reliability, and safety become matters of first consideration.

We have thus to distinguish between two kinds of power transmission, the one taking place over distances reckoned by feet or yards, and the other over distances reckoned by thousands of feet, or even by miles. When we speak of the electric transmission of power, we tacitly assume that it belongs to the latter class, and refers to distances beyond the reach of the ordinary gear, such as shafting, cog-wheels, pulleys, and belts, employed for the subdivision and distribution of power within the walls of a factory; and it is in this generally accepted sense that I propose to bring the subject mainly before you. There are, however, cases where the application of electromotors to special tools is either the most convenient or only possible method of applying mechanical power to the performance of certain operations, and it will, therefore, be necessary, at least briefly, to glance at that part of our subject which is not usually comprised within the title of these lectures, namely, the transmission of power over very short distances by means of electric currents. We thus distinguish between "long distance" and "short distance" transmission, the fundamental distinction between the two being that, in the former, the transfer or transmission of power from one point to another, so to speak, in bulk, is our main object; whilst in the latter we rather aim at the subdivision and convenient application of power, in small quantities, at various points, and for particular purposes. I propose to consider long distance transmission first.

Broadly speaking, there are two ways in which we can transmit mechanical energy from one place to another. Let us assume, by way of example, that the primary source of energy is coal, and that the power derivable from this coal is required, not at the pit's mouth, but at a mill a certain number of miles away. In such a case, the obvious, and also the most economical, way of transmitting power is to carry the coal to the mill, and burn it under the boiler of the mill-engine. Even if the distance between the pit and the mill is short, this method will be the best, provided there are no difficulties of transport. Suppose, however, that, although the distance is short, local conditions, such as great difference of level, bad roads, or total absence of roads, render the carriage of coal difficult or impossible, then we would establish our boiler and engine at the pit, generate the power there, and transmit it by wire rope, or in some other way, to the mill. In both cases we have transmission of power, but the methods are essentially different. In the first case we have transmitted, not mechanical, energy itself, but the thing from which mechanical energy can be obtained, namely the coal, each ton of which represents so many stored horse-power hours. In the second case we have transmitted the energy itself in its kinetic or potential form. In popular language we might describe the process as the transmission of "live" power, as distinguished from the transmission of "stored" power, which takes place when we carry coal from the pit's mouth to the mill.

The most important sources of power in nature are corn, coal, and falling water. Under the term "corn" I comprise all vegetable food-stuffs suitable for conversion into mechanical energy, by means of horses and other animal engines; whilst the term "coal" naturally includes all kinds of fuel suitable for conversion into mechanical energy by some form of heat-engine. The power derived from corn and coal is generally transmitted in the stored form; that derived from falling water in the live form, since the conveyance of water at a high level, or under considerable pressure, to great distances necessitates the erection of very costly works. To prevent misunderstanding, I must here point out that I use the term "stored energy," as applied to water, merely in its colloquial sense. We speak of the energy stored in the water of a mill-pond, but, in reality, the energy does not reside in the water at all, but is an effect of its elevated position, and is, therefore, not comparable with the energy which is chemically stored in coal. Leaving, however, such distinctions on one side at present, we may regard water, which is being carried along horizontally, at a certain elevation, from one place to another, as the vehicle of so much stored energy, which we can obtain, in its live form, at any point at which we establish a water-engine, through which the water passes in its descent to a lower level. If we carry water along in this way, it is not with the object of bringing the stored power to the point of application, but merely to secure the largest possible fall, and, therefore, a maximum of power with a given quantity of water. If it be necessary to transmit the power farther, the transmission is generally effected in the live form. Now let us see what position electricity occupies in relation to these primary sources of power in nature, namely, corn, coal, and falling water.

In the first place it will be obvious that, where electricity is the transmitting agent, we can effect the transmission both in the stored and in the live form. To see this clearly, we need only for a moment revert to our example of the coal pit and the mill. Instead of sending the coal to the mill to be converted into power there, we could burn it at the pit, and thereby generate steam to be used for driving a steam dynamo. The current from the dynamo we could utilise in charging a storage battery, and send this to the mill, where it would drive an electromotor, thus taking the place of the local steam engine. Here we have a system of transmitting energy in the stored form. On the other hand, if we do away with the batteries as a vehicle of energy, and connect the dynamo at the pit with the motor at the mill by a pair of insulated wires, we have a system of electric transmission of power in the live form. The latter system is that generally understood under the term "electric transmission of power," and therefore forms the principal subject of these lectures; but before entering upon it, I propose briefly to investigate the capabilities of electric transmission of power in the stored form.

As you all know, a sack of coal contains more stored power than a secondary battery of equal weight, and its carriage, whether by rail or road, is cheaper, easier, and requires less precautions than that of the battery. It is, therefore, quite obvious that, if the primary source of power is coal, and if there is no objection to the establishment of a steam-engine at the place where the power is wanted, it will be more economical to carry the power there in the form of coal than in the form of batteries; not only because of the saving in carriage, but also on account of the smaller capital outlay, the smaller depreciation, and the avoidance of the loss of energy in the battery itself. But let us assume that the primary source of energy is falling water, then it is not so obvious at the first glance that its electric transmission in the stored form should be uneconomical. We cannot produce coal out of the energy of falling water, but we can charge batteries with it, and electricity would thus seem to offer a means of utilising a power of nature which would otherwise be lost. It might, perhaps, here be objected that electricity does not form the only means for utilising such a power, since there are various other ways in which power may be stored, a familiar example being compressed air. We might therefore, also utilise the power of the waterfall for working an air compressor, and store the air under pressure in steel reservoirs, to be used afterwards for working air-engines constructed similarly to ordinary steam-engines. Many such engines are actually in use in Paris on the Popp system, though there the air is conveyed to them by pipes under pressure, and not in

* Cantor Lecture I., delivered before the Society of Arts, February 16, 1891.

Digitized by Google

storage vessels, as would be the case in our example. There can thus be no doubt that the transmission of power by stored air is practicable, but the question is, at what cost will it be effected, and can it compete with transmission by batteries? The answer to these questions depends on two factors, namely, the storage efficiency and the cost of transport. By storage efficiency, I mean the ratio of the power put into and taken out of the apparatus which serves as the vehicle for the power. Batteries may now be obtained in which this ratio is about 80 per cent.; that is to say, for every 100 H.P. hours put into the battery, 80 H.P. hours can be taken out. The storage efficiency of compressed air is very much smaller. The most reliable data under this head are to be obtained from the Paper which Prof. Kennedy read before the British Association in 1889, when he gave an account of experiments carried out at Paris on the Popp system. He found that the indicated efficiency with cold air was 39 per cent.; that is to say, for every 100 H.P. indicated by the compressing-engine, 39 H.P. were indicated in the engine driven by compressed air as it came from the mains. If the air before being admitted to the engine was heated to 320°F., the apparent indicated efficiency rose to 54 per cent., but as the heat energy thus supplied to the air requires the expenditure of fuel at the point where the power is wanted, the use of hot air really involves two methods of transmission—namely, that of power in the shape of air under pressure flowing through the mains, and that of power in the stored form contained in the fuel. To make the comparison with electric transmission of stored power a fair one, I must therefore take the efficiency of the Popp system when the air is not heated. A correction must, however, be made for loss of power in the mains. In the Popp system the power is transmitted in the live form by air flowing through pipes, and there is necessarily a certain loss on account of friction in the pipes and valves. As far as the friction in the pipes is concerned, this would not occur if the transmission were effected in the stored form by means of air carried under pressure in a reservoir, but, on the other hand, the loss by friction through valves would be greater, because it would be necessary to insert between the reservoir and the air-engine a reducing valve, which would regulate the supply of air as the pressure falls. The loss of power due to this circumstance will probably be greater than the corresponding loss in the Popp system, where the pressure is constant; but as I have no experimental data to determine this point, I take the same loss as found by Prof. Kennedy, namely, 2 per cent., which makes the indicated efficiency nearly 40 per cent. The efficiency of the air-engine he found to be, with cold air, 67 per cent., making the total efficiency of the system 26·7 per cent. By adopting air storage we could, therefore, obtain 26¾ H.P. hours for every 100 H.P. hours indicated in the engine. Now let us see how the case stands with electrical storage. The efficiency of the steam dynamo, that is, the ratio of the electrical output to the indicated power, may be taken as 83 per cent., that of the batteries 80 per cent., and that of the motor at least 85 per cent.; so that the total efficiency works out to quite 56 per cent., or more than twice that of the rival system. I have here assumed that the dynamo is steam-driven, simply because the only reliable figures I could obtain about compressed air referred to steam-driven compressors, but it is obvious that the comparison of the storage efficiencies of the two systems cannot be materially affected by the source of power, and will practically be the same in the case under consideration, where the power is supposed to be derived from falling water. We see that in efficiency, at least, air storage is far behind electrical storage. Let us now inquire whether it is any better off in the other essential feature I have mentioned—namely, in the cost of carriage. The information available under this head is tolerably reliable as regards batteries, but this is not the case as regards air stored under pressure. I know of no experiments made to determine accurately the weight of air reservoirs, and, in the absence of such data, I cannot do better than adopt the calculated figure given by Prof. Osborne Reynolds in one of his Cantor lectures delivered in 1888. According to this authority, the weight of the steel reservoir and air contained would amount to 300lb. for ever horse-power hour so stored. Now the weight of a secondary battery filled with liquid, and provided with a tray and connections, all complete, does not exceed 100lb. per horse-power hour stored, that is, only one-third the weight of an equivalent air reservoir. We see, therefore, that as regards efficiency air storage is twice as bad, and as regards weight it is three times as bad as electric storage. Competition with it is, under these circumstances, obviously impossible, and we may therefore say that if the transmission of power from the waterfall to a distant point has to be made in the stored form, electricity is the only agent which need be considered.

Whether it would pay so to transmit power is a question which cannot be answered off-hand. As compared with the direct transmission of live power by means of a pair of wires, the cartage of batteries up and down the country will no doubt appear to be a clumsy device, but when we are investigating the different possible solutions of an important problem we must not allow any preconceived opinions of what is elegant or clumsy to influence our judgment; we must, in fact, judge each case on its own merits, and I propose to deal with the electric transmission of stored energy in this sense. The system of power transmission by storage batteries is actually in use, not, indeed, for long distance transmission pure and simple, as above defined, but still for transmission over distances reckoned by miles. I allude to the electric tram-cars worked by storage batteries, which are charged at a central depot, and run for many miles before they require to be again charged. The object is not to carry a certain amount of power in bulk from one point to another, but to dispense whatever power is required for the propulsion of the car during the journey. We might, however, imagine the tram-car, instead of being occupied by passengers, to be loaded with storage cells in addition to those it carries for its own propulsion. Whilst the latter would gradually lose their charge in transit between the two terminuses, the former would arrive fully charged, and could be made to give up part of the power stored in them at the starting point. Here we have transmission of power in the stored form, but let us return to our example of the waterfall and the mill, and see how such a system might be put into operation.

At the waterfall we establish the necessary hydraulic works, and an electric station where the batteries can be conveniently charged. We further build a tram line or railway, joining the charging station with the mill where the power is wanted, and we design the rolling stock with special regard to the safe and convenient carriage of the batteries to and fro. The train is fitted with electromotors, so as to make it self-propelling. A train load of charged cells is thus taken to the mill, and left there to work the electromotor which supplies power to the mill During this process the batteries become gradually exhausted, and must be disconnected from the motor before they are quite exhausted, because we must allow a sufficient margin of power for taking the train back to the charging station. The economy of the whole system will evidently be the greater the less power is spent in the outward and home journey; and we might call "efficiency of transmission" the ratio of the power actually delivered to the motor, and that which might be so delivered if the battery were used for working a motor at the charging station itself; in other words, if the distance of transmission were nought. Say, for instance, that a total of 1,000 H.P. hours could be obtained from the battery, if it were discharged immediately, and that the power spent in the outward journey amounts to 50 H.P. hours, then a further 50 H.P. hours will have to be spent in the return journey, and the power obtainable at the mill will only amount to 900 H.P. hours. The efficiency of transmission will, in this case, be 90 per cent. If we double the distance between the waterfall and the mill, the efficiency of transmission would be reduced to 80 per cent; if we treble the distance, the efficiency would only be 70 per cent., and so on. The efficiency must naturally depend on the kind of road over which the transmission takes place; it will be small on a common carriage road, larger on a tramway, larger still on a railway, and largest on a canal. We can, for every arrangement, express the value of the system, as far as economy of power is concerned, in one of two ways. We can, if the distance is fixed, give the efficiency in the usual way as a percentage, or we can fix a standard percentage of efficiency, and ascertain the distance over which this standard is attainable in any particular case. I shall adopt the latter way of reckoning, as the more convenient for comparison with other methods for transmitting power, whether in the stored or live form.

First, as to transmission of stored power otherwise than by batteries. The only two methods we need consider are the carriage of corn and the carriage of coal, each combined with the use of a proper engine for converting the stored into live power at the other terminus of the iine of transmission. In the case of corn, the starting point of this line is the field where the corn is grown. We there load it into suitable vehicles, and send it to the mill where the power is wanted. Since we are dealing now entirely with animal power, we must suppose the cartage to be effected by draft animals, say horses, and the conversion of corn into live power at the mill also by such animals. I need hardly say that, at the present time, no English mill owner would dream of working his mill in this fashion by animal power, since coal is yet abundant, and a single steam-engine is a far cheaper and handier instrument for producing and controlling a large amount of power than an equivalent number of horses. On the other hand, if power is required in small quantities, and in particular ways, then the horse will produce this power better, more cheaply, ahd more conveniently than the steam-engine. It may seem absurd to work a large cotton mill by horse gear, but substitute for the mill a farm, and you see at once that the transmission of stored power to it, in the shape of corn, is a necessary part of the agricultural operations. Now, the horses, in bringing the corn to the place where the power is required, perform work, and must consume an equivalent amount of food. They also perform work in bringing the empty carts back again to the field to be re-charged. The ratio between the amount of corn delivered at the mill and the amount taken out of the field would therefore re-

Digitized by Google

present the efficiency of transmission. If this is to be 90 per cent., as in the case of electric transmission, we may take it that, for every 100 sacks of corn taken away from the field, the horses would eat on the outward journey (when the carts are heavily laden) 6½ sacks, and on the homeward journey (when they are empty) 3½ sacks, leaving 90 sacks of corn to be converted into live power at the mill. The distance to which we can thus carry stored power with a standard efficiency of transmission is a measure of the merit of the system, as far as economy of power is concerned.

The transmission of stored power in the shape of fuel is a parallel case. We load the coal at the pit's mouth into waggons, and haul them by means of locomotive engines to the places where the power is wanted. Part of the coal is consumed on the outward and homeward journey of the train, leaving the rest for the production of live power at the mill. If this amounts to 90 tons out of every 100 tons put on the train at the pit's mouth, we have again an efficiency of transmission of 90 per cent.

I have already mentioned that the exact distance to which we can carry power by either of the three agents here mentioned (namely, batteries, corn, and coal) depends very much on the kind of road over which the transmission takes place. We might assume an almost infinite variety of cases, but, as our object is to obtain a rough general comparison of the different systems rather than exact figures for any one of them, I have assumed merely three kinds of roads, namely, a common carriage road, a tramway, and railway, and have calculated the distance to which power can be transmitted in each case with a loss of 10 per cent. The results of these calculations are given in the following table. The speed of transmission has been assumed at four, six, and twenty miles for road, tram, and rail respectively, when coal or batteries are the transmitting agents; and at four miles on all kinds of road where corn is the transmitting agent. In all cases I have assumed that the road is the best of its kind, perfectly free from gradients or curves, and that the traffic can be worked at the speeds mentioned without interruption. In reality, these conditions will of course not all be fulfilled; we have to make allowances for waste of power on gradients, curves, bad places in the road, for running at variable speed, and for stopping and starting. The distances given in the table are, therefore, throughout too large; but, as our purpose is merely the comparison of the different systems, we may take the figures in the table as a rough indication of the merits of each.

Transmission of Stored Power.

Source of power.	Distance in miles attainable with 90 per cent. efficiency of transmission over :—		
	Road.	Tram.	Rail.
Coal and steam engine	115	270	1,300
Corn and horse	52	170	440
Storage battery and electromotor	4	10	26

You will see, from this table, that as regards efficiency, the electric transmission of stored power cannot compete with the other two methods. A horse and cart carrying corn over an ordinary carriage road works with twice the efficiency of the electric locomotive taking batteries over a railway. The discrepancy is still greater if we compare the electric locomotive hauling batteries with the steam locomotive hauling coal. The latter can transmit power over a distance fifty times that over which the former can transmit power with an equal efficiency. On a tram line the distance over which we can transmit power with an efficiency of 90 per cent. is, according to the table, 10 miles; that is to say, if the whole load of the car is composed of batteries, we can run it 10 miles out and 10 miles home at an expenditure of 10 per cent. of the total charge of the batteries. Now let us see how this compares with the storage cars in use on passenger tram lines. The total weight of a full-sized car is about 10 tons, made up somewhat as follows :—Car and propelling gear, 4 tons; batteries, 2½ tons; passengers, 3½ tons. If the 3½ tons represented by the passengers were utilised for additional storage cells, the car could run 20 miles with the loss of 10 per cent. of its charge; or it could run 200 miles if losing the whole of its charge. As there are, however, only 2½ tons of batteries instead of 6 tons, it can only run 86 miles. This is according to the table, and more than attainable in practice, for the reasons already stated. Experience has shown that storage cars can only run from 30 to 60 miles with one set of batteries, or half the distance stated in the table. If we apply the same reduction to all the methods of transmission, we find that the distances to which power can be carried electrically in the stored form, with an efficiency of 90 per cent., are two, five, and 18 miles over a carriage road, tramway, and railway respectively.

The efficiency of transmission is, however, not the only or even the most important consideration in the problem of transmitting power to a distance. The owner of a transmission plant cares nothing for any theoretical perfection in the way of high efficiency. All he cares for is the cost at which the power is delivered to him. All other things being equal, high efficiency will naturally reduce this cost, and, in so far, is an advantage, but in practice all other things are not equal, and to aim at high efficiency regardless of other considerations is the reverse of good engineering. It is no doubt gratifying to the engineer if he can point to a transmission plant designed by him to give some extraordinarily high efficiency, but if this result has been obtained by means of an exorbitant capital outlay and excessive working expenses, it will not be equally gratifying to his employer, the owner of the installation, who has to pay for its erection and working. It therefore becomes the duty of the engineer so to plan the installation that the cost of the power delivered shall be a minimum under any given circumstances.

We have seen that, as judged by the efficiency standard alone, electric transmission of power in the stored form is hopelessly behind the other two methods which we compared with it. Let us now see whether this is or is not the case if we judge the system by the more practical and, indeed, the only reliable test of cost. It is, of course, understood that, in estimating the annual cost at so many pounds per horse-power delivered, we take into account not only the cost of coal burnt throughout the year, if we obtain the power by steam, or the rent for water if we use a turbine, but also all other expenses which may properly be charged to the power account, such as wages for the attendants, petty stores, interest, repairs, and depreciation of plant. Estimated in this way, the cost of water power will be found to vary between £2 and £8 per annum, the exact figure depending, of course, on the total amount of power available, the quantity of water, its fall and local conditions, which must largely influence the cost of the hydraulic works. The cases where water-power can be had at so low a price as £2 a year are exceptional; on the other hand, if we have to pay as much as £8 a year for water-power, it will seldom be worth while to transmit it electrically, or in any other way; and I shall, therefore, assume £3 and £6 as the limits of cost for water-power intended for electric transmission. The cost of steam power, if produced by large economical engines, is generally taken at £10 per year; if produced by small, and therefore less economical engines, it may rise to £20, and even £40 per year. I shall further assume that in all cases the power is required for 3,000 hours during the year, that is, 300 working days of 10 hours. At the outset, it is clear that if we wish to transmit large parcels of power—say 100 H.P. and upwards—by storage batteries, we must be able to deliver the power at a cost higher, it would obviously pay better to establish a local steam-engine. I have already mentioned that a system of battery transmission can be made to yield 56 per cent. efficiency, if we allow 10 per cent. for the transmission itself. To deliver 100 H.P. we must, therefore, charge with 178 H.P. during a time equal to that during which the power is required. If, therefore, at the generating station the annual horse-power costs £3, the charge for power alone will be £5. 6s. at the receiving station. To this must be added the cost of labour and the interest and depreciation of plant, which, in this case, consists of the generating dynamo, motor batteries, and line of transmission, with its equipment of locomotives and waggons. The small storage cells, as now made, for lighting and power purposes, cost about £40 per horse-power; but let us assume that the larger cells, such as we would require, could be had for £30 per horse-power, then a battery to work a 100 H.P. motor would cost £3,330. In order to economise carriage, and to reduce the wear and tear of cells, it would be advantageous to have two batteries, one being charged while the other is at work. We have thus an initial outlay of £6,660 for batteries alone. The interest and depreciation on these will certainly not be less than 15 per cent., or £10 per horse-power. Add to this, the cost of power at the generating station, that of labour and interest and depreciation on the electric machinery and the line, and you will see that it is quite impossible to compete with battery transmission against a local steam-engine, if the power produced by the latter costs £10 per annum. But how does the case stand, if the amount of power required is so small that it cannot be produced at this low figure? If we want only 5 H.P., and if we produce it by a local steam or gas engine, we shall have to pay for each horse-power £20 to £40 per annum. Will it, in this case, pay to transmit, by means of batteries, the power produced by a large and economical steam-engine at some central station? If we have to build a tramway or railway for this purpose specially, it will certainly not pay; but let us assume that a tramway already exists, and let us investigate whether the company, which we suppose is working the line by storage cars, could afford to sell to a customer on the line power at a cheaper rate than he could produce by a local engine. Let us assume, by way of example, that the customer requires 5 H.P. for 10 hours daily. The battery to work a 5 H.P. motor will weigh about 2½ tons, and cost £170. The charging dynamo, motor, and regulating gear will cost about £150, so that the whole capital outlay, if we provide two batteries, will amount to £490.

(To be continued.)

ELECTRIC LIGHTING BY MUNICIPAL AUTHORITIES.*

BY PROF. HENRY ROBINSON, M.I.C.E., M.I.E.E.

The supply of electricity to the community may now be regarded as one of the requirements of the day, and it is of first importance to municipal authorities to consider the expediency of preserving the supply in their own hands. Many have lost the opportunity, and have allowed companies to obtain powers over their areas. Many are now deliberating upon the point or are in conflict with companies, and, as I think, the question is ripe for decision, and I hold that it is not so advantageous for these undertakings to be carried out by private enterprise, and by outside capital, as it is by capital raised on the rates, whether from a financial or public point.

As regards finance, the authority can provide the necessary capital at a far lower rate than a company can; and as regards convenience, the public lighting of the streets, the disturbance of roads, and the sanitary advantages of substituting electric light for gas in dwellings, point to their being matters that clearly devolve on the authority to deal with.

I think it will be useful to put on record in your *Proceedings* calculations that I have made of the relative cost of gas and electricity which have appeared in various reports of mine, when advised on the subject of electric lighting.

Table *showing Cost of Gas Lighting.*

Description of Burner.	Candle-power.	Comsumption of gas per hour per lamp.	Candle-power per cubic foot used per hour.	Cost per hour with gas at 2s. 9d. per 1,000 cub. ft.	
				Per lamp.	Per c.p.
		Cubic ft.		Pence.	Pence.
Ordinary batswing ...	10	4·3	2½	·142	·0142
Flat flame from ...	11·5	4·6	2½	·152	·0132
Flat flame to ...	13·8	4·6	3	·152	·0110
Flat flames in clusters	60	15	4	·495	·0083
	90	20	4½	·66	·0073
	150	30	5	·99	·0066
Special form requiring motive power ...	120	10	12	·33	·0028

On an average, it may be assumed that each private lamp in London will be used for 1½ to 2 hours per day throughout the year, whilst in the suburbs it will be used 1 to 1½ hours per day. In shops open till nine o'clock, each lamp will be used three hours per day, and for public-houses, restaurants, &c., each lamp will be used four to five hours per day throughout the year. The annual cost of gas would thus be in a private house with 30 lights used on an average 1½ hours a day, or 547 hours per annum:—

	£	s.	d.
547 × 30 = 16,410 lamp hours at ·152d. ...	= 10	7	11
Add for rent of meter ...	0	14	0
Annual cost ...	£11	1	11

The cost of gas-piping and ordinary (not ornamental) fittings may be taken as follows:—

Workshops and factories ...	20s. to 25s. per light.
Shops ...	25s. to 35s. „
Private houses (with 20 to 40 lights) ...	30s. to 40s. „

The actual cost of producing a Board of Trade unit of electricity may be taken at about 2½d., excluding the provision for the sinking fund, or 3½d. per unit including that provision. At the rate of 3½d. per unit the cost would be as follows:—

·0135 × 12½ = ·169d. per lamp hour, including renewals.

	£	s.	d.
16,410 lamp hours at 169d. ...	11	11	1
Add for rent of meter ...	0	14	0
Total ...	£12	5	1

If the current is charged at 6d. per unit (which is lower than most companies charge, and will yield a profit to the authority) the cost per candle-power per hour will be about ·022d. per lamp hour, or 0·275d. including renewals, in which latter case the cost of the 12 c.p. lamp would be £19. 10s. per annum, instead of £12. 5s. 1d.

For workshops and factories the cost of ordinary fittings for electric light will be from 25s. to 30s. per lamp.

Shops ...	30s. to 40s. per lamp.
Private houses (with 20 to 40 lights) ...	35s. to 45s. „

I will next deal with public lighting, which concerns municipal authorities very closely. For street lighting the arc light is the most economical. The smallest size of arc lamp at present manufactured requires a current of about five amperes, but for steadiness and efficiency it is desirable not to use less than six amperes. The candle-power of arc lamps varies considerably according to the angle at which it is measured. The greatest intensity with continuous-current lamps is found at an angle of about 40deg. below the horizontal line. The following table gives the approximate candle-power at various angles. The height of the lamps should be arranged so as to give an angle of not less than 7deg. to the most distant point which it is intended to serve:—

Lighting Power of Arc Lamps.

Current in amperes.	Horizontal.	At angle of 7°.	At angle of 10°.	At angle of 20°.	Maximum at angle of 40°.
	c.p.	c.p.	c.p.	c.p.	c.p.
6	92	175	207	322	460
8	156	300	350	546	780
10	220	420	495	770	1,100

The following table gives the cost of working arc lamps:—

Current in amperes.	Average candle-power at angle of 20deg.	Watts required.	Units used per hour.	Cost of current at 3½d. per unit.	Cost of carbons ·50 and fixing ·16.	Total cost per lamp hour.	Cost per average candle-power per hour.
				Pence.	Pence.	Pence.	Pence.
6	322	300	0·3	1·05	0·66	1·71	·00531
8	546	400	0·4	1·40	0·66	2·06	·00377
10	770	500	0·5	1·75	0·66	4·21	·00313

The last column in the table gives the cost per candle-power per hour, and these figures are arrived at by dividing the "total cost per lamp hour" by the figures representing candle-powers "at an angle of 20deg." (given in the table of lighting power), which represents a fair average of the power from arc lamps. The last column in the table of cost admits of comparison with the last column of the table previously given of the cost of gas.

Arc lights should be placed high up for the following reasons:—1. On account of their high candle-power and great distance apart. 2. Because the light thrown down at an angle is much greater than that cast horizontally. 3. Because the light given horizontally is not so steady as that which is thrown down at an angle.

The following data enable the coefficient of minimum lighting power in streets to be determined:—

Let P = candle-power of lamps.
L = maximum distance from lamp in feet.
H = height of lamp in feet.
X = a coefficient.

The light falling on a unit area of pavement varies inversely as the square of the distance from the lamp, and is directly proportional to the angle at which it falls. This angle is nearly proportional to the height of the lamp divided by the distance. Therefore,

$$X = \frac{P}{L^2} \times \frac{H}{L},$$

or

$$X = \frac{P\,H}{L^3}.$$

The usual standard of gas lighting is represented by the amount of light falling on a unit area of pavement 50ft. away from a 12 c.p. gas lamp 9ft. high, which gives a co-efficient as follows:—

$$X = 12 \times 9/50^3 = ·000864.$$

Adopting the above coefficient, I calculate that the before mentioned sizes of arc lights will give the same standard of light at the heights and distances stated in Table A.

Table A.

Current in amperes.	Height of lamps.			
	20ft.	25ft.	30ft.	35ft.
	Maximum distances served from lamp in feet.			
6	160	175	190	202
8	185	202	220	235
10	205	225	243	260

Table B gives the corresponding distances, assuming the minimum standard to be doubled, thus bringing the coefficient up to

* Abstract of a Paper read before the London Meeting of the Association of Municipal and County Engineers.

Digitized by Google

·001728, which represents the amount of light on a unit area 50ft. away from a 24 c p. lamp 9ft. high :—

Table B.

Current in amperes.	Height of Lamps.			
	20ft.	25ft.	30ft.	35ft.
6	130	144	155	166
8	150	165	180	193
10	170	190	205	220

The distances the lamps are apart would, of course, be double the distances mentioned in tables A and B.

One arc lamp will take the place of from three to six gas lamps, according to the locality, arrangement, and standard of light adopted.

A scheme of arc lighting, based on the substitution of one arc light on the average for 3½ to 4 gas lamps, would double the minimum standard of light, whilst the average standard would be increased 10 or 12 times.

Placing lamps along the middle or the streets has the advantage of illuminating the fronts of the houses more uniformly, and this advantage is more apparent when the lamps are of higher candle-power than that of the present gas lamps. Moreover, in business thoroughfares the footways are often fairly illuminated by the shop-lights, whereas the middle of the road is thrown more into shadow. The regulation of traffic in crowded thoroughfares would be much assisted by a well-considered system of large lights and shelters or refuges, and the cost of police control over traffic in streets likely to become congested would be reduced thereby, whilst the number of accidents would diminish.

A higher standard of street lighting appears to be inevitable in the near future, even if it is attended with increased cost. This is evidenced by the fact that authorities are now directing their attention to affording a much larger amount of light in main thoroughfares than has heretofore been accepted as sufficient. In carrying out a system of public lighting by electricity, the fact that the lights can be instantaneously switched on and off at a central station may be taken into account. By having a second main, and by connecting the lamps alternately to the two mains, every alternate light could be switched off at, say, midnight, and a saving effected in the annual cost. It should be noticed that with public gas lamps an appreciable time is taken up in the operation of lighting and extinguishing, by which the lamps that are first lighted and last extinguished have been consuming gas beyond the actual time that is needed for lighting purposes. A series of electric lights, on the other hand, admit of being switched on and off at the central station at the exact time required by the season, so that practically the number of lamp hours in the case of electric lights is less than with gas lights to the extent of several hundred lamp hours per annum.

THE GORDON CLOSED CULVERT SYSTEM OF ELECTRIC TRACTION.*

There are four well-known methods of conveying the electrical energy from the central station to the motor on the car.

The Storage System.—This system possesses the great advantage that it can be applied to existing tramways without any alteration in the permanent way, provided the latter has been built sufficiently strong to stand the great weight of these cars and the increased wear and tear. Unfortunately, however, the system is very costly both to instal and in running expenses.

Overhead System.—In this system bare conductors are led overhead from the central station along the whole length of the track, and connection is made between this and the motor on the car by means of a pole attached to the roof of the car. The unsightly poles and cross-arms erected along the street are an eyesore and inconvenience to the public, and all the objections against overhead telegraph and telephone lines apply with much greater force to overhead tramway lines. It may be taken as a foregone conclusion that neither in Great Britain nor in most of the principal Continental towns will the overhead system ever be tolerated.

Open Culvert System.—This system has produced most excellent results, but is very costly to instal. It involves digging up the concrete foundation to a considerable depth, and almost rebuilding the tramway.

Closed Culvert System.—In this system a surface conductor is formed of a series of short lengths of mechanically strong conductor, fairly well insulated from one another, usually running along midway between the permanent way rails, and with their upper surfaces flush with the roadway. Underneath is a closed culvert, containing a well-insulated and main conductor leading from the central station, but the short lengths of surface conductor are electrically connected with the main conductor only when covered by a passing car. My object is to bring before your notice a new method of working this system which solves all the difficulties and meets all the requirements mentioned above.

The Gordon Closed Culvert System is an improved surface conductor system, the improvements being chiefly in the means of establishing and breaking connection between the main conductor and the surface conductors, in simplification of the closed culvert, and in dispensing with all moving parts under the roadway. Extensive experiments on this system have been carried out during the past 12 months on a full gauge line at Messrs. Merryweather and Sons' Engine and Tramway Works, Greenwich, S.E., with the most satisfactory and encouraging results. In the Gordon system, instead of using a complicated automatic mechanism for each short length of surface conductor, a number of such conductors are grouped into a section, and one electro-magnetic switch or distributor works the whole group. As the surface conductors are about 8 or 9ft. long, and 30 or thereabouts are grouped into a section, the distributors are few in number—about 20 per mile—and spaced about 90 yards apart. They may, therefore, be placed advantageously in boxes under the pavement, immediately inside the kerb stone, and the conductors may be tested, withdrawn, and replaced with little or no disturbance to the traffic. The culvert is the simplest imaginable, being an ordinary 2½in. gas pipe with T-pieces every 16 or 18ft., that is, opposite every alternate break in the surface conductor. At or about the centre of each group of surface conductors, this longitudinal pipe is fitted with a small T-shaped junction box from which a cross pipe leads to the distributor box under the pavement. The top of this T-shaped junction box is movable, to facilitate the drawing in and out of conductors. The main well insulated conductor is placed in a longitudinal pipe along the length of the track, and from it a branch is led to each distributor box through the cross pipes. The openings in the T pieces in the longitudinal pipe are plugged, and through the plugs are led well-insulated service leads, one from each short length of service conductor to the distributor which operates the section of which it forms an element. It might at first strike one that this plan involves a great outlay in insulated copper conductors, but such is not the case. With 30 lengths of surface conductor per section the total length of service leads is seven miles per mile of track, and as a car is always supplied by two service leads in parallel, each has to carry only one half the current necessary for one car during the time occupied in travelling over 8 to 9ft—that is to say, about one second at normal speed. The service leads may, therefore, be of comparatively small section. A 7/18 conductor will be sufficient for all ordinary requirements. The fall of potential has to be considered rather than the carrying capacity, as the absence of sparks in the distributor depends upon the former being kept small. The small outlay in service leads is more than compensated for by the absence of moving mechanism under the roadway, the simplicity and small dimensions of the conduit, and the consequent minimum of disturbance to the existing track involved in adopting it to this system.

The distributors are simply a number of electro-magnets (one for each length of surface conductor) excited by a shunt current only. (One terminal of each is connected to the corresponding service lead and the other terminal to the return). Each magnet operates three contacts, one when it is excited and two when it is not excited. Of the latter two, only one is actually in use at any given time, which one depending upon the direction in which the car is travelling. The connections are so arranged that before the car can receive a supply through any given surface conductor the corresponding magnet must be excited, and the two magnets corresponding to the surface conductors next but one in advance and next but one in rear must not be excited. The car carries two collectors, or slippers, placed apart about one-third the length of the car, and electrically connected together, and to one terminal of the motor. These rub or slide along the surface conductor, and the current, after passing through the motor, is led through the permanent way rails back to the source of supply. (In cases where the use of the rails as a return might be objected to, an insulated return can be provided without the introduction of additional surface conductors into the roadway, and at a small extra cost). As the car advances, and the forward collector touches a surface conductor not yet charged, the latter becomes charged by reason of being short circuited with the charged conductors in rear. A current passes through the corresponding service lead and magnet to earth, and the latter, becoming excited, operates two contacts, one of which puts the surface conductor just entered upon into communication with the main conductor, the other at the same time cutting out the next but one in rear. During this operation the car receives its current through the surface conductor lying between these two.

* Abstract of a Paper read before the Tramways Institute, on July 2nd, by Mr. John Gordon.

Digitized by Google

The main current is thus never interrupted. When no current is required, as, for instance, when the car is at rest or going down hill, the conductors under the car are always charged, the current used to propel the car operating in no way to effect this. This result is brought about by the combined movements of the collectors along the surface conductor, and of the contact makers in the distributors. I have stated that when any magnet is not magnetised it closes two contacts, but that only one of these is in use at any given time. This arrangement is to enable the car to proceed in either direction at any moment. The experiments on this system, which have been carried out at the works of Messrs. Merryweather and Sons under circumstances so trying as to put a severe strain on any system, have been attended with such success as to justify the anticipations of those who were made acquainted with the system, and satisfy its supporters as to its practicability and ultimate success. The work had to be carried on without interfering with the busy traffic in a large engineering works; the track has been repeatedly flooded with water during the testing of fire engines, and the distributors themselves have frequently come in for an occasional copious shower bath. It has been suggested to the writer that, if the track were very wet, a current sufficiently large to energise one of the magnets might leak across from a charged surface conductor to the adjoining one, and thus put the movements in the distributor out of step, so to speak, with the movement of the car. Were such the case the difficulty could be easily and effectually remedied by attaching to the rear end of the car a supplementary slipper, electrically connected to the frame of the car or to the return lead. This would put each length of surface conductor to earth or zero potential immediately the car passed over it. In practice, however, it has been found sufficient to make the distance between the surface conductors about three inches; but the above device, being so simple, might be advantageously used as an additional security against any possibility of the distributor getting out of step with the car or a charged surface conductor being left exposed. The cost of adapting an existing tramway to this system would be about £2,000 per mile of single track.

PARLIAMENTARY INTELLIGENCE.

THE CHELSEA ELECTRIC LIGHTING PROVISIONAL ORDER.

The Select Committee of the House of Lords, presided over by Lord Basing, had before them, on Thursday, the Electric Lighting Provisional Orders (No. 10) Bill, which confirms certain Provisional Orders, relating to the City of London, Clerkenwell, Middlesex, Woolwich, and St, Luke (Chelsea). The Bill was unopposed except with reference to the St. Luke (Chelsea) Order, which confers power upon the new Cadogan and Belgrave Electric Supply Company to supply the electric light to a part of the parish of St. Luke, Chelsea. The Vestry of Chelsea petitioned against this Order, on the ground that, if it passed in its present form, the district over which they had control would be injuriously affected.

Mr. T. Holland, clerk to the Vestry of Chelsea, appeared to oppose the Bill; Mr. Cripps, parliamentary agent, supported it on behalf of the London County Council; and Mr. Muir Mackenzie represented the promoters.

Mr. HOLLAND, on behalf of the Chelsea Vestry, said the Order, as drawn up by the Board of Trade, contained clauses making the London County Council the local authority under it. The Vestry of Chelsea objected to those clauses. They were the authority in the case of the Chelsea Electricity Supply Company, which supplied the electric light to 215 houses in the parish. It might be contended that no objection was offered by the Vestry to the Order of the London Electric Supply Corporation, confirmed by Parliament in 1889, but he would point out that the area covered by that Order extended to nearly the whole of the metropolis, and the parish of Chelsea only formed an integral portion of that area; moreover, the generating station of the London Electric Supply Corporation was situated at Deptford. The undertaking, therefore, could not in any sense be regarded as a local one, and the Vestry recognised the expediency, in that instance, of a metropolitan authority for a metropolitan Order. The Electric Lighting Acts of 1882 and 1888 specified the Vestry as the local authority for all purposes under the Acts, except within the limits expressly assigned to the Metropolitan Board of Works, and the latter Act, which confirmed the definition clause of the earlier one, was passed in the same Session as that in which the County Council was constituted, and, therefore, it was not the intention of Parliament to give control or powers over electric lighting to any other authority than the local authority as defined in those Acts. If the County Council were made the local authority under the Order, a concurrent jurisdiction would be established, which might, and probably would, lead to conflict between the Vestry and the County Council, and by the Order, as it stood, when the Vestry became the undertakers the County Council would exercise an authority over their supply, which should be left to the inhabitants of the district, subject to a reference to the Board of Trade, as it was under the Electric Lighting Acts. Clause 36 of the Order provided that the inspectors should be appointed by the County Council. That provision appeared to be in direct contradiction to the provisions of sub-section (*e*) of section 6 of the Electric Lighting Act of 1882, which, in specifying the regulations to which the undertakers were to be subject, and which, therefore, were the only regulations which the Board of Trade could make in any Order under the Act, expressly provided for the appointment of the inspector of the local authority. Much confusion would also arise from the operation of such a clause, as the following cases would show:—The Cadogan Electric Light Company was a Chelsea company. Their generating station was close to the centre of the parish—in fact, much more so than that of the Chelsea Electricity Supply Company. Both companies were proposing to light King's-road. The Baths Commissioners—who were practically a committee of the Vestry—might take electricity from the Chelsea Electricity Supply Company, and the Vestry might take theirs from the Cadogan Company, and if the lights were bad at the baths the Commissioners might require an electric inspector to test their wires. The Vestry would have power to appoint the inspector, but if their own lights were bad at the Town Hall they would have to ask the County Council to appoint the inspector, as the Vestry would have no power over the Cadogan Company.

The CHAIRMAN: You have no objection to this new power being granted provided that the Vestry are made the local authority?

Mr. HOLLAND: None whatever.

The CHAIRMAN said the Committee desired to hear why a double jurisdiction had been set up in the parish, and whether it was essential.

Mr. CRIPPS, on behalf the London County Council, said the Council were appointed the local authority under the Order of the London Electric Supply Corporation of 1889.

Mr. HOLLAND interposing, said the London Electric Supply Corporation could not in any sense be regarded as a local one. It only supplied the current to two houses within the parish under the control of the Vestry.

The CHAIRMAN said the Committee were unanimously of opinion that, under this Order, the Vestry should be the local authority.

Mr. MUIR MACKENZIE said the promoters had no objection to the amendment.

Mr. CRIPPS said the amendment proposed to be made in this Order would have the effect of altering the existing legislation in regard to electric lighting in every parish in London.

The Bill was amended in accordance with the petition of the Vestry, and ordered to be reported to the House.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 27, 1891.

The Incandescent Lamp Patent Litigation.—It is expected that some decision in the great incandescent lamp case will be reached about the middle of July. The amount of evidence is so enormous—many thousands of printed pages—that it is almost out of the question to expect an early decision, even if the documents were read only in abstract.

The Edison Feeder Patent.—The final evidence is now being taken in the feeder and main patent of the Edison Company. The defendants in this case are really two, both the Thomson-Houston and Westinghouse companies being involved. The case against the latter will probably come up first, however. The feeder and main patent, like the incandescent lamp claim, is one concerning which there may be a good deal of doubt. The prevailing impression seems to be that, of the two, the lamp case is the strongest for the Edison Company.

Aluminium Smelting Dynamo.—A rather interesting dynamo has just been completed in this city for use in aluminium smelting works soon to be erected. It is designed by Mr. T. L. Willson, and is intended for a capacity of 7,000 amperes with potential as high as 110 volts if desired. The weight of the new machine is about 30,000lb., and its armature, a Gramme ring 24in, in diameter and 47in. long, weighs nearly three tons. There is no commutator; the brushes rest directly on the bare bars of copper that form the armature winding. The efficiency has not yet been tested, inasmuch as the machine has not been run under load. The loss from hysteresis, eddy currents, and friction appears to be very small.

The Westinghouse Company.—The affairs of the Westinghouse Company still appear to be somewhat unsettled; the annual meeting, which was to have been held a few months since, was adjourned until the middle of July, owing to the arrangements for transfer of stock being not yet complete.

The Electric Traction Business.—Of the larger electrical companies, the Thomson-Houston seems to be doing the most active business at present. It, and the Westinghouse Company are making considerable inroads in the street car business

Digitized by Google

that has been previously held by others, and the Short Company is not behind in this respect. The reason for this may be found in the introduction of slow-speed and gearless motors which have been vigorously exploited during the spring.

Storage Battery Traction.—It is gratifying to record even the temporary success of storage battery traction. During the last winter and spring some six or eight storage battery cars have been in operation in Dubuque, Ia., and recent reports from there are giving most encouraging accounts of the results. The cars of the Electrical Accumulator Company's system are still in the hands of its experts, but they have been running very regularly through a rather severe winter with very few breakdowns, and very little trouble of any kind. The expense, of course, is the unknown factor, but so far as successful service goes they appear to have been doing admirably, and the repairs incurred have, it is said, been far less than were made on a much smaller Edison-Sprague road running under somewhat more severe conditions in the same town. Altogether the Dubuque road appears to afford more encouragement to the friends of storage battery traction than has been accorded it for a considerable time past.

CORRESPONDENCE.

THE NEW RULES FOR THE TECHNOLOGICAL EXAMINATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your editorial note on page 235 you are good enough to refer to the changes which are to be made henceforth in the examinations in Electric Light and Power conducted for the City and Guilds of London Institute by Mr. Kapp and myself. Whilst thanking you for the terms of commendation in which you speak of the Finsbury Technical College, I would ask you to permit me to point out that these examinations in Electric Light and Power are not confined by any means to the College at Finsbury, but are held at many different centres all over the country, for the students of all the classes in this subject that are taught under the scheme of the City and Guilds' Institute. The new regulations apply to the examinations that will be held in May, 1892.

Will you further permit me to point out that in the "Ordinary" grade there is no longer a separate examination in electrical instrument making; and that in the "Honours" grade the subject is divided into three separate parts, for but one of which a candidate can compete relating, respectively, to put it briefly, to (1) Electrical Measuring Instruments, (2) Dynamos and Motor Construction, (3) Central Station and Contracting Work.—I am, Sir, &c.,

SILVANUS P. THOMPSON.

City and Guilds' Technical College, Finsbury.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to one of the leaderettes in your last issue, it will, doubtless, interest you to know that the system of engineering examination which you advocate, was, I believe, originated, and certainly was used, nearly twenty years ago by my father, Dr. Wm. Anderson, F.R.S., now Director-General of H.M. Ordnance Factories, when he on several occasions conducted examinations at Cooper's Hill Engineering College. As well as I can recollect, he used to set Papers, which the students worked out at home or in their rooms, and they had a week or so allowed to do them in, and were at liberty to use any books or notes that they could get hold of, just as they would do in practical work; in fact, they might do anything short of asking other people to do the work for them, or tell them anything about it. He used also to hold a *viva voce* examination, and I think this and the Papers above mentioned were all that he required to be done.

I believe he found the plan thoroughly satisfactory, and I understand it has been adopted now at University College, London.

I give the above from memory, and may be wrong in some of the minor facts, such as to time allowed for working the Papers, &c., but the principle of it is correct.—I am, Sir, yours, &c.,

E. W. ANDERSON.

3, Whitehall-place, S.W., July 6, 1891.

ELECTRIC RIVETTING PATENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the notes published in your issue of May 29th, under the heading "Electric Rivetting Patents," the statement of the decision by the Examiner of Interferences in the United States Patent Office is given, in which priority of invention was awarded to Mr. E. E. Ries. It may interest you to know that this decision has been reversed on examination into the merits of the case by the Board of Examiners in Chief, and that on every point the ruling has been against Mr. Ries, contrary to the statement which has been hitherto published. The only point that was under dispute in the matter that entered into the case, was concerning my own diligence in working the invention.

The concluding statement of the decision referred to reads as follows:—"Thomson thus has an impregnable record at all points. We are wholly unable to see a case for Mr. Ries, in any aspect. We find Thomson to be the prior inventor, and reverse the decision of the Examiner of Interferences."—I am, Sir, &c.,

ELIHU THOMSON.

Lynn, Mass., June 25, 1891.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

"THE ELECTRICIAN"

ELECTRICAL TRADES' DIRECTORY & HANDBOOK for 1891.

The 1891 edition of our well-known Directory and Handbook is ready, price 5s., postage extra. The book consists of over 900 pages, and has entailed this year a heavy amount of work. The HANDBOOK DIVISION contains a mass of most useful information. The DIRECTORY DIVISION consists of 430 pages, and contains a very carefully compiled Alphabetical and Classified List of Firms and Persons engaged in the Electrical and Allied Trades in all parts of the world. This Division has been corrected up to date, and the book is thoroughly reliable, the very numerous changes which take place at the beginning of the year being incorporated. By the aid of this Directory, makers of Electrical Machinery, Apparatus, Instruments, Fittings, Sundries, Novelties, and other goods, may safely communicate direct with probable customers without the annoyance and great expense consequent upon using books which are mere lists of Members of Scientific Societies repeated again and again. The Colonial and Foreign Division of this Directory will be found extensive and reliable. *Orders should be forwarded at once.*

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all, Vol. I., 20; Vol. II., 18), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

TENDERS INVITED.—The London County Council invite tender for making perfect and maintaining in thorough repair for three years the whole of the electric bells and wires, and the apparatus connected therewith, fixed in the land and river stations of the Fire Brigade, and in houses used as lodgings for firemen. Specification, form of tender, and particulars may be obtained on application at the County Hall, Spring-gardens. Tenders, addressed to Mr. H. De la Hooke, clerk of the Council, Spring-gardens, S.W., endorsed "Tender for Maintenance of Electric Bells," to be sent in by noon on Tuesday next, the 14th inst. Persons tendering must have offices and workshops within the County of London.

SALES BY AUCTION.—We would remind our readers of the sales by auction on Tuesday and Wednesday next, by Messrs. Hobson, Richards, and Co., at 36, Albert-embankment, of the valuable plant, machinery, and stock of the Electrical Engineering Corporation (Limited). The machine tools, plant, and stock of the Quintin Matsys Forge, Griffin-street, York-road, S.E., will also be offered for public competition next week, Messrs. Wheatley Kirk, Price, and Goulty being instructed to dispose of the same on Thursday next. Particulars will be found in our advertisements columns.

CHARLESWORTH, HALL AND CO., OLDHAM.— Messrs. John Rankine and Sons, Consulting marine and electrical engineers, Africa

Digitized by Google

House, Leadenhall-street, London, and Corporation Quay, North Shields, have been appointed as agents for the Tyne, Wear, and Tees shipbuilding centres by Messrs. Charlesworth, Hall, and Co.

DISSOLUTION OF PARTNERSHIP.—The partnership between Messrs. Urquhart and Bates, electrical engineers, 11, Victoria-street, Westminster, has been dissolved. The business will be carried on by Mr. David Urquhart.

BROWN'S ROTARY ENGINE.—Prof. Jamieson has made a test of this engine, and has given a report on its performance. The report does not, however, give an intelligible account of its construction or action, and we defer publication of it until we are able to describe and illustrate it.

THE "PILSEN" ARC LAMP.—We have received a note from the Pilsen Electric Company in which they state that in their lamp they have succeeded in eliminating all the intricate parts, replacing the same with simple and substantial devices, and that they now claim the lamp to be one of the shortest, lightest, steadiest, safest and cheapest in the world. The Company state that the lamps are now made for direct or alternating currents, for parallel or series burning, and for photographic purposes. We are glad to learn that they are withdrawing the licenses for manufacture under royalty, since a number of very badly made lamps, professing to be of this make, have come under our notice. They intend in future that the lamps shall be made solely by themselves.

COMPANIES' MEETINGS & REPORTS.

The National Telephone Company (Limited).

The eleventh ordinary general meeting of the shareholders of this Company was held at the City Terminus Hotel, Cannon-street, E.C., yesterday (Thursday). Mr. Frederick Richards Leyland presided.

The SECRETARY (Mr. Albert Anns) having read the notice calling the meeting, the CHAIRMAN said: I presume you will take the report and accounts as read, as you have had them in your hands for some days. If so, I propose to go through the report and accounts, and elaborate a little what I have to say. The report has given you the main features of what the transactions of the past year have been. I hope you will consider the results satisfactory, inasmuch as the net revenue account—notwithstanding the heavy reductions that we have made in our rates in the provinces – still leaves us with an increased balance over last year, sufficient to pay the same rate of dividend on a much larger capital, and to carry to reserve fund the same amount as we did last year; and although we carried forward a little less than we did last year, this is, to some extent, accounted for by an item you will see in the net revenue account of £1,388. That amount arises in this way: We last year estimated the dividend to come from the subsidiary companies in which we hold shares at £1,388, and it was so credited in the accounts. Unfortunately, those companies declared no dividend at all, and we were advised, therefore, to put this right in this year's balance-sheet, so that last year got credit for £1,388 which did not belong to it, and this year gets its balance diminished by a corresponding amount in order to set that right. When you take that amount into consideration, which makes in the comparison about £2,800, the difference in what we carry forward this year and what we carried forward last year is a comparatively trifling amount. The next thing I have to remark upon is this: There is a very large amount at the debit of net revenue account, £8,053, "expenses *re* issue of new debenture stock." Well, you all remember perfectly well what the state of the money market was when that issue of £350,000 was made or placed on the market, and, after considering the matter very seriously, we came to the conclusion that it would not have been a wise thing if we had taken the risk of placing the whole of that amount. We thought it was a wiser thing to underwrite a portion of it—£200,000—and to make that, at all events, secure. The cost of that is shown in the accounts. The underwriting, for one thing, is about £7,600, and the rest is for stamps which we were compelled to pay on issuing the debentures. We might have charged that over a number of years, which is a very ordinary practice, but we thought it was a much better thing to put it all to the year, and let each year bear the losses and charges of that year. Then I have to refer to the extension of the Company's business during the year, which is dealt with in the second clause. I have only carried that up to April 30th, the date when these accounts finish, but I may as well tell you that the increase of revenue has gone on since then. The revenue, which, on April 30th, reached £418,560, increased on May 31st to £422,273, and on June 30th to £424,899. You, therefore, see that we are steadily going on with the increase in our rental. The number of subscribers, of course, increased to a corresponding extent. On April 30th the number was 35,440; on May 31st it had increased to 36,131; and on June 30th it rose to 36,655. You see therefore that, notwithstanding the large reductions of rates which we made in the provinces, we have already made up, and more than made up, the loss in our annual rental. Of course, we have had a great deal more work to do for this—more lines to keep in order, more operators to pay, and we have had to make very large additions to our capital expenditure, on which we shall have to pay dividends and interest to our shareholders and debenture holders. The problem, therefore, is still this—How far will this increase go on? Probably by the end of our next year, when I meet you again, I hope (and the figures all point to it) that I shall be able to state that increase has gone on to such an extent as to provide for all the extra expenses, and to make our net revenue and net profit just as good as at present. Of course, it is not my business to prophesy. I can only point out what I think, the figures which I have indicated, and what the probable course of things will be, and then you can judge just as well as I can. There is one thing, by the way, I missed, and you must never forget it. This year's accounts only bear the loss of January, February, March, and April, the first four months of the year. The remaining eight months will fall on next year, and the point is whether the progressive increase will be enough to make up for the loss. The gross rental, it is perfectly clear, will do so; but the next question is—Will the net result do so? With respect to the working expenses, I do not think there is anything I need say beyond what I have said before. In clause 3 we say:—"The number of exchange and private line subscribers over the whole of the Company's system, excluding the South of England district, which last year was 29,257, was on April 30, 1891, 35,440, an increase of 6,183 subscribers during the year, and the number of subscribers is still increasing. The Directors are still acting upon the conviction that it is of vital importance to continue the policy of developing and improving the Company's system, and of giving greater facilities to the public." Last year I spoke at considerable length upon this subject, and told you what we were doing—changing all the shackles into cross arms and insulators, the looping of the junction wires, and the substitution of magneto bells for the ordinary battery bells. We have still gone on with that work. We have done fully one-third of the whole of it, and some of it we have completed altogether. We have still about one-third of that work to do. I think I told you at the time that it would take three years to do it, and we have still the third year's work to do. Of course, you can all understand that the progress, considering that we have to do this work while the ordinary daily service of the Company is going on, must necessarily be slow. It is much more difficult to work under these circumstances than it would be if you had a free hand and a new system to go on with. There is also another disadvantage, namely, that with all the care we take—and the men take every care they can—we cannot avoid contacts between wires when they are working on the roofs of houses. That, of course, brings on us complaints from subscribers, and I can quite understand their complaining bitterly. Till we get the work completed, I am afraid we shall not be able to avoid this. We state in the 5th paragraph: "The Directors have taken over the business of the South of England Telephone Company (Limited), which is now merged in this Company." In all the comparisons I have mentioned I have left out the South of England Company, as it will not be included for the whole year. In the 6th paragraph we say:—"On the amalgamation, in July, 1889, of the three principal companies, it was thought desirable that the customary annual retirement of one-third of the Directors should not take place at the end of the first year, in order that the numerous arrangements rendered necessary by the amalgamation and reorganisation of the Company might not be interfered with. These having been now completed, and two of the provincial companies, the Northern and South of England Telephone Companies having been absorbed, the Directors think they ought all, at this meeting, to place their offices at the disposal of the shareholders, and submit themselves for their approval. They, therefore, now all retire, and being eligible, offer themselves for re-election." I have really very little to say on this subject. I think the report has given you all that has to be told to you on that point. The Directors have been very glad to take this opportunity of placing their positions at your disposal. They have thought it was their duty to do so. They place themselves in your hands with the consciousness of having done all that they could in carrying on a very intricate and responsible business, and we hope that what we have done will meet with your approval. I do not think there is anything more that I have to say, but I shall be glad to answer any question.

A brief discussion followed.

Mr. LEAKE thought the general interest account was very large, and it would appear to represent an average of about £100,000. He thought they were going too fast in their expenditure, and he wished to know how they proposed to find the capital for the extensions advocated.

Mr. HARRIS asked if the Directors had taken into consideration the question of putting the lines in better order. His firm had had two lines, one of which was private, which, however, they had given up for an exchange line, and now they had two exchange lines. They had complained to Mr. Anns, who had answered with every courtesy, and the London Manager appeared to have done, he admitted, all that was in his power to improve matters. He thought that at the present juncture the Company should do all they could to improve the service.

Mr. BLACK asked that the expenses might be given in more detail.

Mr. BIDEN also trusted that the service given by the Company should be improved, and thought it a serious matter that a body of their subscribers had combined together with the view of getting their grievances rectified by the Company. With regard to the amalgamation of the new companies, they stood at £230,000 in the accounts, and 6 per cent. on this amount would be nearly £14,000, whereas the accounts for the present year showed nothing like this increase in their net profits.

The CHAIRMAN: Now, Mr. Leake, I will answer you first. This large amount of general interest account—£4,650—you are quite right about. When we made that issue of £350,000 we were heavily indebted to our bankers. You know the rate of interest at that time was pretty high, and that is the explanation of it. You suggest that we ought to go along rather more slowly.

A SHAREHOLDER: Go ahead as fast as you can.

The CHAIRMAN: I do not think you will find that the meeting agree with the view that we should go more slowly. I take a different view. I may be wrong, and you may be right; but I say that the salvation of the Company is to push on as quickly as you can, and thus cover the ground. I do not think you will find the meeting with you on that point. As to

Digitized by Google

the Directors' fees, the amount of the division of them—which is a question also of Mr. Beck—I wrote and gave the information required. There is no wish on my part to keep any information from the shareholders that I think it prudent to give them, and which I can give them without injury to the interests of the Company. As you know perfectly well, by the Articles of Association the Directors' fees are £5,000. They have the power of electing from among their own number an executive committee to attend here every week from Liverpool, Manchester, Glasgow, and other places, and to fix their remuneration. We have fixed the remuneration of the executive at another £5,000, and that makes the total cost £10,000. There were 13 Directors to divide that amongst; most of them had to work very hard. I had to work pretty hard myself, and I put it to you whether you think it is too much; if you think so, you have only to say so. Now, in reply to Mr. Black, I can only tell him what I said in my letter—that to divide all these expenses of management and operators' wages would be giving information which would be very valuable to our opponents, and which I do not think would be of very much use to the shareholders. Then Mr. Harris spoke about the lines, and complaints not being attended to. I have always admitted that there are great complaints, and I have told you this very day—that these complaints cannot cease until we get this system put right. We took over a system which was radically bad, and which had to be thoroughly reorganised. That had to be done while the work was going on. It is like a railway, and Mr. Forbes or anybody else can tell you what difficulties there would be in carrying on work when you had the whole service going on.

Mr. HARRIS said he understood that their line had been put in order.

The CHAIRMAN: Then, in that case, I wish you would come and see me.

Mr. HARRIS said that he could not waste his time in this way.

The CHAIRMAN: I am ready to "waste" my time. If Mr. Harris will come and see me I shall be glad to go into the matter; I might then be able to obtain the information as to whether inspectors or any one on the staff were not doing their duties. I have been asked how we are getting on with Hasties' Committee. We have seen some of the members. It is a committee which has names of very great weight and value upon it. We are trying to arrange a meeting with most of those gentlemen, and we will put the thing clearly before them. It is not want of zeal on our part, but we must do one thing or another; we must either stop the service, which evidently we cannot do, or we must go on and do the best we can while the service is proceeding, and, of course, we are subject to these complaints. We are not going to let that matter slide. Mention was made about the amalgamation of the Northern and South of England Companies. The South of England Company was practically taken over within the last month or six weeks. We shall have to go into that and carefully analyse it, but there is not much profit in it now, neither was there in the old Northern Company. But we have turned that into a profitable thing, and I hope we shall be able to do the same with the South of England Company.

Mr. BIDEN asked whether the Directors would in future state their fees separately in the accounts.

The CHAIRMAN said that he had stated them to the meeting, and he wished to know the object of their putting the amount in the account. He inquired if it were the wish of the meeting that they should do so.

A SHAREHOLDER thought that it was very undesirable to publish such information—an opinion which was received in the room with manifestations of approval.

The CHAIRMAN enquired if any other Shareholder wished to address the meeting, and no one rising to continue the discussion, he proposed the following resolution:—

"*That the Report and Accounts, be taken as read, be received and adopted, and that a dividend be paid for the last half-year at the rate of 6 per cent. per annum, less income-tax, on the amounts paid up on the 1st and 2nd Preference Shares, and at the rate of 7 per cent. per annum, less income-tax, on the amount paid up on the Ordinary shares, making, with the interim dividend already paid, 6 per cent. for the year ending April 30, 1891.*"

Mr. J. S. FORBES: I beg to second the resolution. The Chairman has dealt so exhaustively with the position of the Company and the accounts that he has left me little to say; but I think I must say, by way of supplement, and to enforce what he has said already, about the numerous complaints—well-grounded complaints—which we receive, that they do really arise from circumstances which the Directors cannot govern. You have to remember the awful complications of a city like London, and you have to remember that we have no legal *status*. We are acting on sufferance. Those two facts will at once explain why the service in London is not as satisfactory as it might be; and you cannot reconstruct and carry on a business without great time and trouble in face of difficulties which, in my experience—and it is pretty wide—have never been encountered before. It is well that this should go forth to the public, and that they should understand what is the cause of our difficulties. If they understood the difficulties against which we have to carry on our business the complaints would sometimes, at all events, be less strongly stated. The fact is that people who complain do not understand the difficulty of the work as we do, and no men have ever set themselves more determinately to work to overcome the difficulties than the directors of this Company.

The CHAIRMAN then put the motion in the usual manner, and declared it carried unanimously.

Mr. FORBES then took the Chair.

Mr. F. FAITHFULL BEGG proposed the re-election of Mr. Leyland. He stated that that gentleman had been connected with the Company since the amalgamation, having been previously a Director of the United Company. Since Mr. Leyland became President of the National Company—the amalgamated Company—he had devoted himself day by day, and week by week, to the management of their affairs. He was convinced that the shareholders could not do better than re-elect Mr. Leyland as their President.

Mr. BALFOUR seconded the motion, observing that the best test of the success which had followed the untiring zeal and devotion of Mr. Leyland in the Company's behalf was indicated by the report which the Directors had presented to the shareholders on that occasion.

Mr. FORBES fully endorsed the remarks of Mr. Begg and Mr Balfour, and observed that the Directors, had it been necessary to speak on this subject, would have been justified in speaking in even higher terms of the services which had been rendered by their President. He put the resolution, and it was carried unanimously.

The CHAIRMAN, in acknowledging his re-election, promised to do his utmost in the future to promote the welfare of the Company, as he had done in the past.

Mr. FITZGERALD then proposed the re-election of the Vice-Presidents, Mr. Forbes and Colonel R. Raynsford Jackson. He spoke highly of the services which had been rendered by these gentlemen to the Company, and said he thought the shareholders would agree with him that it was an honour to have two such gentlemen on the Board of the Company.

Mr. W. A. SMITH seconded the motion.

The CHAIRMAN said he concurred to the fullest extent with what had been said regarding the qualities of Mr. Forbes and Colonel Jackson. He put the resolution, and it was carried unanimously.

Mr. RIDSDALE proposed the re-election of the Directors of the Company—Messrs. C. S. Agnew, John Bruce, Peter Garnett, Eli Heyworth, W. C. Quilter, M.P., George H. Robertson, Samuel H. Sands, and Alderman Joseph Thompson. He warmly testified to the services of these gentlemen, and expressed a hope that they would get the West of England Company amalgamated with the National Company. He enquired how the Bill in Parliament for giving the Company statutory powers was going on.

The CHAIRMAN: We are preparing it. It is not to be deposited until the month of November.

A SHAREHOLDER seconded the motion.

The CHAIRMAN put the resolution and declared it carried unanimously. The Chairman afterwards referred to the retirement from the Board of Mr. Batten and Mr. Parrish, and stated that they proposed on the present occasion to fill up one of the vacancies by the appointment of Mr. William Alexander Smith. He then proposed a resolution electing Mr. Smith to a seat ta the Board.

Colonel JACKSON seconded the motion, and stated that Mr. Smith was eminently qualified for the position.

The motion was carried unanimously.

A vote of thanks to the President, Vice-Presidents, and Directors was then proposed and seconded in eulogistic terms, and was carried by acclamation.

The CHAIRMAN acknowledged the compliment, and the proceedings then terminated.

The India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

The half-yearly general meeting of the Company was held on Thursday, at the City Terminus Hotel, Cannon-street, for the purpose of declaring an interim dividend. Mr. S. W. Silver, the Chairman of the Company, presided.

Mr. WILLIAM J. TYLER, the secretary, read the notice convening the meeting.

The CHAIRMAN: Gentlemen, the notice just read contains the object of our meeting, and, in accordance with it, I move that an interim dividend of 5 per cent. be paid forthwith; and I feel fully justified in doing so as the sales during the past year in the general branch of business are in excess of last year, which was the largest in amount of any previous year. And this, I am glad to say, applies also to the foreign factories. When we last met, reference was made to the contract for laying on the Chilian coast of South America 1,700 miles of submarine cable. I have now to report the results to be in all respects satisfactory, notwithstanding the many difficulties arising out of the revolution along the coast where this cable has been laid. The greatest credit is due to the engineer-in-chief, Mr. Hamilton Gray, for the tact and ability displayed in the interests of our Company, and for his good judgment, which has been, I may say, recognised in a substantial way by the English Government. The captain and officers of the vessel "Silvertown" supported him ably, as did the electrical staff. During the last few months the telegraph department has been fairly well employed. On her return from Chili, the steamer "Silvertown" had only time to turn round, refit, and take on board 1,600 miles of submarine cable for the Western and Brazilian Company. She started a fortnight ago, and is now approaching her destination, the east coast of South America. I have no doubt of our being able, at the close of the year, to render satisfactory accounts of our operations, notwithstanding the keen competition that prevails. Now, gentlemen, in thanking you for your attendance here to-day, it merely remains for me to move—

"*That an interim dividend of 5 per cent., or 10s. a share, free of income-tax, be paid on and after the 10th inst.*"

Mr. NEIL BANNATYNE: I beg leave to second that motion.

The motion was put, and carried unanimously.

The CHAIRMAN: Our business, I believe, concludes with that; but perhaps the Managing Director would like to say a few words.

Mr. MATTHEW GRAY, the Managing Director: The Chairman has clearly stated the position of the Company, as far as I can judge. He said the ordinary business of the Company is somewhat better than last year.

Digitized by Google

It is very little better, and I am sorry to say that the competition is so great in that part of the business that there is not very much profit attaching to it. I think it is as well to let you know that. I think I may here state that we intend laying a cable between the coast of Africa and Brazil. We have got a concession from the Brazilian Government which enables us to do this. We have started manufacturing the cable, which will keep our mills going for some while.

The CHAIRMAN : Well, gentlemen, that, I think, terminates our business.

Sir WILLIAM WALLACE : I think there is one thing to do before we separate, and that is to vote our thanks to the Chairman and Directors for their management of our business, and I think I may trust that, although we are only making small profits, as Mr. Gray says, we shall probably have a very good dividend when the end of the year comes. And I should like to add to that our thanks to the staff on the steamship "Silvertown," and the rest of the staff of the Company. I am sure the Directors would like that added.

Mr. JOHN OLIVER HANSON : I beg to second that.

The proposition was carried.

The CHAIRMAN : I thank you, Sir William, and gentlemen, for your kind remarks, which will only increase our attention to your interests generally, and make us more earnest ; and as regards the staff, I may say that I am glad you have felt it incumbent to pass that vote, for your thanks to them are thoroughly well deserved.

The meeting then closed.

New Shanghai Electric Company (Limited).

An extraordinary general meeting of the above Company was held at the office on May 20, Mr. J. Beattie in the chair.

The SECRETARY having read the notice calling the meeting,

The CHAIRMAN said :—Gentlemen, the object of the present meeting is to ask you to respond to a call for increased capital, so as to carry out an important proposal for the extension of the Company's business. Although there has been steady and satisfactory progress made during the 2½ years' existence of this Company, the figures of this year so far showing a further marked improvememt, yet it is manifest to the directors, as well as to others well posted on the subject, that anything like full justice cannot be done to the Company without the requisite means to meet all applications. The arc department has not developed much, certainly, though the lighting of the Kinleeyuen wharves is a promising sign, but, pending improvements in the arrangement of the lamps, will make the light more valuable to the community, and may possibly induce the Council to extend the support hitherto given, and so much appreciated by the Company. The success of the incandescent light is so fully recognised in the Shanghai Club, as well as in the hongs where it has been so far installed, that a further unmistakable demand has arisen for it, in some cases from very important quarters ; and as Shanghai is not a poor community, the first cost does not deter many from adopting a good and steady light which does not hurt or vitiate the air :— a too obvious boon in the hot and oppressive weather. In addition to the profit derived from the two systems of lighting, the prospects of future remuneration from the supply of material look promising, as a contract has just been confirmed for the installation of one of the local steamers, and we have to-day been asked for estimates for two others. Under all these circumstances, a capital of some Tls.47,000 is manifestly inadequate, and the Directors hope that, in accordance with the resolution to be brought forward, the present shareholders will subscribe the additional amount to supplement that already promised, so as to complete the Tls.50,000 odd (or most of it) which is required to place the concern on a stronger footing ; for machinery, &c., has to be paid for before any return can be forthcoming, besides which it would doubtless be expedient to purchase the present or more suitable premises. It is true that the shares are at a slight discount, but this can only be because the position and prospects of the Company are so little understood ; for, excepting unforeseen accidents, there is nothing to prevent the payment of a good dividend, after making fair allowance for depreciation of plant. Apart from the question of capital, another impedient has been the difficulty of obtaining Directors versed in the technicalities of electric lighting, but, to obviate this, Messrs. Morrison and Gratton have generously come forward to offer their services as consulting engineers, which practically means the scientific management of the Company's business, an advantage that cannot be questioned for a moment, as very few are similarly qualified to undertake such a post ; and they are prepared to accept a very moderate commission at first, which proves their confidence in its future development. They have carefully gone into all the calculations, every detail at the works being supplied to them, and they are evidently quite satisfied with the result.

Mr. MORRISON having given a very exhaustive account of the present condition of the Company's works and the need for the proposed increase of capital, which he said could not but be beneficial,

The CHAIRMAN then proposed, Mr. HASKELL seconded, and it was carried unanimously :—

"That the Directors be requested to offer the unissued shares of the Company for subscription on the following terms, viz. : That the shares be issued at par. That each shareholder on the register at the date when applications have to be sent in shall receive the full number of shares he applies for, up to the number of shares he holds at that date. That the remaining shares be divided among the other applicants provided that all applications by shareholders be satisfied before any shares are issued to non-shareholders. That the date of application, amounts and dates of payment of instalments, and other terms be fixed by the Directors. That the shares to be issued shall rank with old shares from the date at which they are fully paid up, and in the meantime shall rank for dividend in proportion to the amount paid up on each."

The Direct United States Cable Company (Limited).

The following report of the Directors of this Company for the six months ended June 30 last, to be presented at the twenty-eighth ordinary general meeting of the Company, to be held at Winchester House, Old Broad Street, E.C., on Friday, the 17th inst., at 2 p.m., has been issued :—

The Directors submit the usual statements of account for the half-year ended June 30, 1891, which, with the half-year's accounts to December 31st last, presented at the ordinary general meeting on January 16th last, show the financial result of the fourteenth year's working of the Company.

The half-year's revenue (subject to revision on settlement of the case mentioned below) after deducting out-payments, amounted to £37,352. 19s. 5d. against £40,017. 1s. 0d. for the corresponding period of 1890, being a difference of £2,664. 1s. 7d. against the half-year under review.

The working and other expenses for the same period, including income tax, but exclusive of cost of repairs of cables, amounted to £18,112. 19s. 8d., leaving a balance of £19,239. 19s. 9d. as the net profit of the half-year, making, with £5,510. 11s. 3d. brought forward from the previous half-year, a total of £24,750. 11s. For the corresponding period of 1890 the working expenses and other payments amounted to £17,616. 5s. 8d.

Three quarterly interim dividends of 3s. 6d. each per share, amounting to £31,872. 15s., have been declared and paid during the financial year, and a final payment of 3s. 6d. per share is now proposed, making, with the three interim dividends, 3½ per cent. for the year, being a total distribution of £42,497. The balance of £3,502. 1s. on the revenue account is proposed to be carried forward.

A break in the short section of cable, occasioned by a vessel's anchor, occurred on January 14th, about 278 knots from Halifax, and was repaired on March 28th, at a cost of £2,188. 4s. 8d., which has been debited to the reserve fund account, as heretofore.

In the action of the Anglo-American Company *v.* Paris-New York Telegraph Company, the question referred to the Council of State has been decided in favour of the Anglo Company, the French Company being ordered to pay the costs. The case will now go back to the Court of Appeal.

Pursuant to the provisions of the Articles of Association, two of the Directors, viz. :—Sir John Pender, K.C.M.G., and William Ford, Esq., retire by rotation, and, being eligible, offer themselves for re-election. Mr. John G. Griffiths, F.C.A., and Mr. John Sawyer, F.C.A., the auditors, retire pursuant to the Articles of Association, and offer themselves for re-election.

The Chili Telephone Company, (Limited).

The following is the report of the Directors of this Company for the year ending 31st March last, to be submitted to the shareholders at the meeting, on Tuesday next, at Winchester House, at noon :—

The action in the Chilian court between the Vendor American Company and a small minority of its shareholders, referred to in the fifth paragraph of the last report, was ready for decision, when, by order of the Government, the courts were all closed and they have not since been re-opened ; as, consequently, the impediment to registration of the Company's title has not yet been removed, the business of the Company is continued in the name of the Vendor Company, but without serious damage to this Company's interests.

The purchase of the business of the National Telephone Company of Chili, mentioned in the ninth paragraph of the last report, has been completed, and the business of that Company, so obtained, has been merged in, and has formed a part of, the business of this Company since 1st July, 1890.

After the outbreak of the civil war the business of the Company was stopped by order of the Government, which has since had the entire use of those of our lines situated within the districts remaining under its control ; but business has been resumed for the public at Iquique, and other stations in districts held by the Congress party. On the 31st March, when the present account ended, the public service at Santiago had been suspended for one month and eighteen days. For the loss of business the Government will compensate the Company, and $62,000 had, on the 31st March, been received on account of such compensation.

The Company's property has sustained damage only in the province of Tarapaca. The parts of Iquique and Pisaqua were bombarded, and several battles fought on land. Some of our instruments were destroyed, and some poles and wires cut down ; for this, both parties are held to be directly responsible, as well as for loss of business between January 20th and March 10th, during which period the telephone service there was suspended by order of the authorities.

The outlay on capital account has been large, but it was necessary for the development of the Company's business, which has already increased, and will be still further considerably enlarged when the trunk lines are finished. The general manager directs "special attention to the fact that our construction in Valparaiso and Santiago is practically completed," and adds that "we may confidently expect in the future that the expenditure of the past year will bear good results, and that, when the present troubles are over, the number of subscribers will be largely increased, with very little additional outlay." From some of the expenditure to connect up towns, no revenue has as yet accrued, because the subscribers have not yet been connected.

Part of the outlay has been in connecting the former "National" system with that previously belonging to the Company—for more economical working—and part in supplying heavy fixtures and pole lines, so that, to complete connections for new subscribers, the small cost of running the wires only will be necessary.

The Traiguen district has been opened up, and this is likely to prove very advantageous to the Company. The locality is on the frontier of

Digitized by Google

Chili and the Argentine, and is the centre of the corn district. The whole of the country round there has been very rapidly developed, and when the railroad, which is in course of construction, passes through, it is expected that this district will become extremely important. It is intended to connect Concepcion with Victoria, Collipulli, and Angol, and eventually with Chillan; but the necessary money for the building of these lines must be furnished by those subscribers who will be benefited by these connections.

The gross and net revenue of the Company show considerable improvement, and, after all proper deductions are made, the balance available for dividend is equal to 7 per cent. per annum upon the paid-up capital, as against a distribution of 5 per cent. for the previous year.

In view, however, of the continuation of the civil war—with very indefinite prospects of its ending—and also in view of the fact that, for capital purposes, it has been necessary to use, temporarily, the income of the Company until the capital exchequer be replenished by further issue of securities—which cannot be done on satisfactory terms at the present time—the Directors recommend that no dividend be paid, carrying forward, undivided, the whole balance of £14,209 10s. 1d., until peace is re established, and the future of the Company becomes more secure.

The Company is now in sole possession of the whole field. Its system is already in far better order than ever before. It has established new exchanges throughout the country, and its prospects—but for the revolution—are brilliant.

In accordance with the Articles of Association, Colonel R. Raynsford Jackson retires from the board of Directors, and, being eligible, offers himself for re-election. The Auditor, Mr. Thomas A. Welton, also retires, and offers himself for re election.

NEW COMPANIES REGISTERED.

CITY OF WATERFORD ELECTRIC SUPPLY COMPANY (LIMITED).—Registered by H. F. Kite, 11, Queen Victoria-street, E.C., with a capital of £1,000, in £5 shares. The object of this Company is indicated by the title.

COUNTY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £100,000, in £5 shares. Objects: to carry on the business of electricians and electrical engineers in all its branches. The first subscribers are:—

	Shares.
J. A. Kelman, 251, Winchester House, E.C.	1

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 687.—Vol. XXVII. FRIDAY, JULY 17, 1891. Price Fourpence.

NOTES.

We have received the following telegram from our New York correspondent:—

Judge Wallace's decision in the lamp case yesterday (14th inst.) was strongly in favour of Edison. He dismissed the technical objections in a sweeping manner, and held that Edison invented a practical lamp. The decison was, therefore, given on general facts instead of details of evidence, and the evidence as to lack of invention and novelty was neglected. An injunction was granted and accounts were ordered. An appeal will soon be taken, and this injunction will be fought. Success is possible, but improbable.

The London Overhead Wires Act (1891), which received the Royal Assent on the 3rd inst., is but a mild measure in comparison with the Bill originally drafted by the County Council. extracts from which were published in our issue of January 30th. In the course of its passage through the House of Commons Select Committee the clauses relating to subways, charges for registration, and uniformed inspectors, were shed; and in the Bill which finally received the Royal Assent the telephone clause with the peremptory heading, "Electric currents not to be interfered with," was also omitted. The net result is merely that the County Council is empowered to make bye-laws, to be approved of by the Board of Trade, and to be enforced and administered by the Vestries and Local Boards of the Metropolis, with regard to the registration, erection, maintenance, and removal of overhead wires.

We publish this week the first portion of an abstract of a Paper by Prof. Mengarini, of Rome, on "Alternating Current Electrolysis." The chief novel result of these experiments seems to be the proof that a voltameter acts towards alternating currents like an inductive resistance. The continually reversing counter-electromotive force of polarisation acts like the counter-electromotive force of self-induction in an inductive resistance, and imposes a lag in phase on the resulting current. Hence the work taken up in the voltameter is not correctly measured by the product of the currents flowing through the electrolytic cell and the volts at the terminals. Such products give a number in excess of the true work. The ratio of this product to the true watts may be anything from unity to double or more.

This has an important bearing on the practical use of water resistances to take up the energy of alternating currents. Generally speaking, by far the easiest and cheapest way of getting rid of the electrical energy developed by alternators or transformers when under test is to send the current into a rough voltameter, consisting of a couple of lead plates hung in a tub of water. Such a plan was used at Thames Ditton, on Tuesday, in connection with the tests described in our leader, and since these water resistances are employed every day in quantitative tests as a means of absorbing energy, it now becomes a question how far the product of amperes and volts taken at the tub do really give the true watts absorbed. It may be that when working at 2,000 volts the impressed E.M.F. is so much greater than any possible counter E.M.F. of polarisation that the product of amperes and volts is not very different from the true watts. Experiments should be made to find out how far this is the case. Moreover, the effect must depend to a great extent upon the current density at the surface of the plates, and it is noteworthy that in Prof. Mengarini's experiments the number of amperes used per square centimetre of electrode was in all cases far greater than would naturally be employed with ordinary water resistances. Henceforth we cannot take it for granted that the water tub and lead plates are the exact equivalent of an inductionless resistance.

The Professor's experiments, indeed, make it clear that, under certain circumstances, the power in watts absorbed by a liquid resistance cannot be estimated from the product of volts and amperes, but the theory advanced to show that the resistance is inductive is not so convincing, and it is quite conceivable that the arrangement acts like a condenser. It has long been known that a couple of lead plates in water act like a condenser as far as slow charges and discharges are concerned, the capacity of the plates amounting to several microfarads per square centimetre. We are, however, unaware that any experiments on the action of such plates with alternating currents have been previously published.

An important point in connection with the interpretation of Hertz's experiments has been recently brought out by M. Bjerkness in some experimental work described in another column. Some time ago MM. Sarasin and De La Rive showed that the oscillations set up in the resonator corresponded with the natural period of the resonator, rather than with that of the oscillator; and, by taking this fact into account, they were enabled to correct some previous deductions from Hertz's researches, and to show that the velocity with which the electric waves were propagated was the same in wires as in air. M. Bjerkness now accounts for the experimental results by showing that the oscillations in the vibrator die away far more rapidly

Digitized by Google

than those in the resonator. It has to be borne in mind that these oscillations all rise and fall in less than a millionth part of a second, while the sparks which start them only occur a few times a second. If, therefore, the oscillations of the vibrator die away before those of the resonator, the latter is left to vibrate like a drum which has been struck once or twice by some vibrator, and the oscillations which persist are accordingly those which are natural to the resonating body. The case would be reversed if the source of the oscillations maintained its power. Thus the membrane of a telephone only gives out the sounds corresponding with the attractions and repulsions of the magnet operated by the current, because, whatever may be the natural period of oscillation of a body, it will, under the prolonged action of a periodic force, vibrate in accordance with the force which is impressed upon it, and any natural oscillations of its own will be suppressed. The observations of M. BJERKNESS are of considerable interest in connection with HERTZ'S experiments; but it still remains to be shown whether the sparking in the resonator occurs before or after the oscillations in the vibrator have practically died away, for in the former case the argument advanced is irrelevant.

IN the early days of engineering, when there was no mechanical science—that is to say, no systematised fund of knowledge accumulated from other people's experience, and when there was but little theory, or overdrafts on experience not yet acquired, it was customary for the millwright to rely on his instinct or his "eye." This guide is not to be despised, even when we have the most solid experience and trustworthy theories; but instinct must sometimes give way before facts. We noticed, at the works of Messrs. WILLANS and ROBINSON, a drawing of a form of bearing which, to the engineering eye, is hideous as an expedient, and is an apparent confession of inability to line up a bearing or to construct a stiff shaft. But this bearing, which may be described as an egg in a napkin ring, was introduced some years ago by one of our leading dynamo builders. It was used on the outer bearing of their machines when mounted on Willans bed plates. Messrs. WILLANS and ROBINSON have made hundreds, and have recommended them to dynamo makers for several years past, and the firm to which we refer have regularly employed it on all their dynamos. To call it a ball and socket is misleading, there is a bit of a ball, but no concave seat; to call it a swivel bearing is an insult to swivels generally; there is no rotation round a pin, though the bearing is skewered in place with a bolt sticking into it. But it is no use maligning it; we understand that these bearings never give any trouble at all; they are therefore perfect, so there is an end of the matter.

Taunton Exhibition.—General Sir J. Lintorn Simmons has consented to open the forthcoming Electrical Exhibition at Taunton.

The Safety of Electricity.—Of the 1,333 deaths due to accidents which occurred in New York in 1890, two, or ·15 per cent., are attributable to electricity.

Thunderstorms.—During the severe thunderstorms of last week, considerable damage was done to property in the East and North of England. In Essex several sheep were killed and some ricks were set on fire. In the North, mills and houses were struck.

The Writing Telegraph.—A test of the writing telegraph was recently made between New York and Chicago, and was fairly successful. A message of 60 words was transmitted without a break.

Transmission of Power at Steyrermuhl.—The 100 H.P. plant for the electric transmission of power, supplied by the Oerlikon Maschinenfabrik, has given such satisfaction that it has been decided to increase its capacity to 460 H.P.

Electric Lighting in London.—An address will be delivered by Mr. R. Percy Sellon on this subject, before the Balloon Society, at St. James's Hall, Piccadilly, on Friday, July 17th, when Mr. Edward Wood, past President of the Institution of Civil Engineers, will preside.

Driving Electric Clocks by Alternating Currents.—According to the *Zeitschrift für Elektrotechnik*, the customers of the Internationale Elektricitäts Gesellschaft, of Vienna, will shortly be able to be supplied with electric clocks. These will consist of small synchronous electric motors, driven from a large clock at the Central Station in Engerth Strasse.

The Sun Lamp.—This arc lamp, better known under the name of *Lampe Soleil*, was remarkable for its steady, soft light, but the marble blocks surrounding the arc dissipated a great deal of heat, and there were many defects in the arrangement. We are glad to hear that Messrs. Woodhouse and Rawson are about to re-introduce it in an improved form.

Chelsea Vestry.—At a recent meeting of this Vestry it was moved:—"That a committee, consisting of 10 members, be appointed to consider and report upon the question of the advisability of erecting a dust destructor, with a view of utilising the refuse for the purpose of generating electricity to be used for the public lighting of the parish."—The motion was carried.

The British Association.—At the forthcoming meeting of the British Association at Cardiff, it is proposed to hold in Section A, if possible in conjunction with Section G, a discussion on "Units and their Nomenclature," having special regard to the new electrical and magnetic units now becoming necessary for practical purposes.

St. Pancras Vestry.—At the meeting of this Vestry, last week, the Electricity Committee reported that they had given consideration to the description of arc lamp columns and lamps required for the public lighting of Tottenham Court-road. Various tenders had been received. The committee had determined to adopt Brockie-Pell lamps, and recommended the purchase of 26 arc lamps and columns.—The report was carried.

Train Lighting Plant.—Referring to the description of the Holmes apparatus which appeared in our issue of May 15th, our attention has been drawn to the fact that the use of two dynamos arranged to give constant E.M.F. over a considerable range of speed has been described in the following patents:—Mordey, No. 342, Jan. 8, 1889; Sayers, No. 3420, Feb. 26, 1889; Holmes, No. 20244, Dec. 17, 1889.

Mutual Telephone Company.—Four hundred and seventy subscribers are now in communication through the Mutual Exchange, and 500 will be joined by July 22nd. By the end of August 700 will be speaking. On July 31st the replacing of the present temporary transmitters by loud-speaking carbon ones will be commenced and finished in about 10 days. The Mutual Loud-Speaking Transmitter has been examined by an eminent firm of solicitors and patent agents, and reported free of all patents owned by the National Telephone Company. On June 30th, the Mutual Company's Manchester system comprised 421 miles of wire.

Electric Transmission of Power at Fribourg.—The municipal authorities of Fribourg are about to instal a hydro-electric transmission of power station at the Sarine dam, outside the town. The contract has been awarded to MM. Cuenod Sautter et Cie, of Geneva, who will instal two 150 H.P. 150 volt machines. Distribution will be effected on the three-wire system. The prices which it is proposed to charge are remarkably low when compared with the tariff elsewhere. Thus the charge for 1 H.P. during a year of 3,000 hours will be 345fr., or 1·15d. per H.P.H. In the case of a 5 H.P. motor, the charge will be 315fr. per H.P. per annum, and 195fr. per H.P. per annum for motors of 21 H.P. and upwards.

Notices of Application for Provisional Orders.—The following notices of proposed application for Electric Lighting Orders have been served:—Chiselhurst Local Board, the Provincial Electric Lighting Power Supply Company; Newington Vestry, Camberwell and Islington Electric Light and Power Supply Company; Middlesbrough, Middlesbrough Electricity Supply Company; Sheffield, Sheffield Telephone Exchange and Electric Lighting Company, Electric Installation and Maintenance Company; Tunstall, Electric Trust; South Molton (Devon), Devonshire Electric Light and Power Supply Company.

The Thomson Watt-Meter.—A test of the Thomson watt-meter, says the San Francisco correspondent of the *Western Electrician*, was made recently in order to satisfy a customer, who complained of exorbitant bills. It was decided to check the light consumption for 48 consecutive hours, and to do this two men were employed. Their instructions were to make note of the exact time to the second of every lamp which was burned or extinguished, and at the end of the 48 hours their report was found to tally with the watt-meter so nearly as to be regarded as correct. In fact, the watt-meter showed a difference of 30 cents in favour of the consumer, the total bill being considerably in excess of $30.

The French Patent Office System.—In connection with the recent celebration of the centenary of the French patent system, *La Lumière Electrique* remarks that it is not, perhaps, generally known that by statutes dated 1666 and 1669 the Académie des Sciences is charged with giving its opinion upon all inventions, the authors of which demanded privileges. By a Royal decree of 1762 it became theoretically obligatory to send every invention to be examined by the Académie, and the "parlement," to whom letters patent were sent for registration, frequently demanded compliance with this formality. The archives of the Académie contain no less than 10,000 reports on patents, some of which are very curious reading.

Electric Traction at Walsall.—At the last meeting of the Town Council the General Purposes Committee reported that, having had under consideration the report of Mr. F. Brown, of the Walsall Electrical Company, they recommend that, subject to arrangements being made by the Company to the satisfaction of the Committee as to the terms and conditions upon which poles, wires, &c., should be placed in the public streets, the consent of the Council should be given to the Tramway Company working their lines by means of overhead wires, and that the Committee should be authorised to employ an electrician to advise them as to the conditions and terms to be imposed upon the Company. The recommendation of the Committee was carried by 15 votes to 5.

The Electro-deposition of Zinc and Aluminium.—The following recipe for an electrolytic bath is given by Kaselowsky, of Berlin:—

Sulphate of zinc	10 kilogrammes.
Glucose	5 ,,
Water	100 litres.
Sulphate of aluminium	200 grammes.

Weak, but constant currents must be employed, and the strength of the bath must be kept up by the addition of fresh quantities of the soluble salts of zinc and aluminium. Kaselowsky has also obtained good results from a bath composed as follows:—

Chloride of zinc	6 kilogrammes.
Glucose	5 ,,
Water	100 litres.
Chloride of aluminium	350 grammes.

Halle.—We have received from the Allgemeine Elektricitäts Gesellschaft, of Berlin, the following additional particulars with regard to the overhead line at Halle, a/S, to which we referred in our issue of November 14th, 1890. The system comprises three lines, which run through the narrowest streets of the town. There are 20 electric cars in operation, on to which one or more trailers can be coupled when the traffic is large. The length of the tracks is about 4½ miles. Soon after the opening of the lines the Post Office authorities considered it necessary to remove to the house-tops the telephone wires, which had been fixed along some streets on the same route as the electrical leads for the tramway. To avoid any disturbances during the removal of the telephone wires, the commissary of police issued an order to the effect that the trams were to cease running on that particular part until the transference was effected. The work was completed in three days.

The Telephone Clauses in the Electric Lighting Orders.—At the last meeting of the Electrical Trade Section Committee, it will be remembered that the Secretary of the Chamber stated that they had approached the Board of Trade on the question of Telephone Clauses in the Electric Lighting Orders, but the reply was considered so unsatisfactory that the idea of sending an influential deputation was abandoned. We learn now that, although it was not communicated to the Secretary of the Chamber, that the Board of Trade had evidently thought better of it and subsequently altered the Provisional Orders by inserting the clauses for the protection of the Telephone Company, desired by the Chamber of Commerce in lieu of those previously inserted. It is believed that the action of the Chamber has in no small degree contributed to this satisfactory result, and we hope that the same body may now be able to achieve an equally satisfactory result in regard to the overhead wires' question; action in regard to which, we believe, was only delayed in consequence of the unsatisfactory reply already referred to.

Train Lighting at the Cape.—In his report for the year 1890, the General Manager of the Cape Railways states that the electric lighting on the Wynberg line and on the express trains has been a great success, so far as comfort to passengers and immunity from accident are concerned. We have not, he says, had sufficient experience to enable us to gauge the comparative expense of the two systems of lighting hitherto adopted; but electric lighting is certainly more expensive than either colza oil or paraffin lamps. Colza oil gives a wretched light, by which it is impossible to read at night with any degree of comfort. Paraffin gives a brighter light; but although we use the most suitable oil (over 150deg.) there is great risk connected with the burning of this class of oil. Although at first the flame may be very moderate, if great care and attention are not paid to the regulation of the wick, the lamp soon becomes so heated that the soldering is melted, and several accidents have taken place from this cause, at the risk of the passengers' lives and of the safety of the carriages. I recommend, therefore, that electric lighting be adopted throughout the three Systems, and shall make provision on the estimates accordingly.

International Electrical Congress at Frankfort.—It has been decided to hold an International Congress of Electricians at Frankfort, in the second week in September, under the presidency of Dr. von Stephan. The chair at the meetings will be taken by Dr. Werner von Siemens, and a Committee, consisting of the Directors of the Frankfort Electrical Company, Dr. Epstein, Prof. Krebs, Dr. May, Herr Lahmeyer, and other well known engineers, has been appointed. A large number of English and foreign electricians have signified their intention of attending the Congress. Meetings, entertainments, and excursions, extending from the 7th to 13th September have been arranged. Amongst the Papers to be read will probably be the following:—Prof. Carhart, "On Replacing Batteries by Dynamos in Telegraphy"; Prof. Dolbear, "Electrical Terminology"; Herr von Dobrowolsky, "The Transmission of Energy by Means of Alternating Currents"; Dr. Frölich, "The Production and Uses of Ozone"; Dr. Kohlrausch, "The Best Training for an Electrical Engineer"; Dr. May, "Lighting Regulations from the Point of View of the Fire Insurance Companies." The Papers and discussions are to be printed in book form, and issued to the members shortly after the termination of the Congress. Tickets, which include a certain number of admissions to the Exhibition, may be had for the sum of 16s., and any further information can be obtained from the Frankfort Electrical Company.

Carlow.—On Monday last, influential deputations of Irish Municipal Authorities were invited by Messrs. J. E. H. Gordon and Co. to view the works which have been established at Milford, near Carlow, for utilising the waters of the river Barrow for the electric lighting of the city. The visitors were shown over the works (which are situated on the ground floor of a large unused mill) by Mr. Gordon, Mr. Rivington, and Mr.

Digitized by Google

Meredith (the engineer in charge of the installation), and they were evidently impressed with the success of Messrs. Gordon's scheme. In the evening a dinner was given in the Town Hall to about sixty of the leading citizens of Carlow and the deputations referred to above, the chair being taken by Mr. Gordon, who was supported, amongst others, by Mr. Hammond, the newly-elected member for Carlow, who has also been for twelve years chairman of the Town Commissioners. It is mainly through Mr. Hammond's efforts that the Local Authority has been induced to give Messrs. Gordon their cordial support. Members of several of the deputations present notified that they had been instructed to prepare reports for the bodies who had sent them, and agreed that what they had seen had given them hope that at no distant time their respective towns would be lighted by electricity. The installation, so far as it goes, is a decided success, although the guests at the dinner had a practical demonstration of the disadvantages attendant upon temporary work, as towards the close of the function the large dining-room was left in darkness. The town lighting was in no way affected.

The Chicago Exhibition.—The decision of the English Government to take part officially in the great Exhibition which will be held in Chicago in 1893 was notified, says *The Times*, to the Government of the United States some three or four months ago, and we are now able to announce that the necessary arrangements have been completed. The Council of the Society of Arts will be appointed a Royal Commission for the purpose of superintending and directing the formation of the British Section, and will receive a grant of £25,000 towards the expenses which will be incurred. This grant is less than any previous one which has been made for a similar purpose, that for Paris in 1857 having been £126,000; that for Paris in 1878, £67,000; that for Philadelphia in 1876, £40,000; and that for Vienna, £28,000. The willingness of the Council of the Society of Arts to accept a comparatively small sum is due to the experience gained at the Paris Exhibition of 1889, when no grant at all was made by the Government, and the expenses of the British Section were defrayed by the exhibitors themselves, aided by contributions obtained by the Mansion House Committee. Sir Henry Trueman Wood, the Secretary of the Society of Arts, filled the office of Secretary to the British Section on that occasion; and the results then obtained convinced him, and have enabled him to convince the Council of the Society, that the Government contribution will be supplemented to any necessary extent. The authorities at Chicago will allot space to the British Commission without charge, and a certain rent will be paid by every exhibitor. This source of income alone, it is believed, will be sufficient to bring up the £25,000 to the full amount which will be required for the expenditure of the Commission.

Indian Telegraph Statistics.—During the year 1889-90 the Indian telegraph system was increased by 6,470 miles of wire, or 6 per cent., the total being now nearly 106,000 miles, Military operations in Upper Burmah necessitated the erection of some 370 miles of line, most of the work being carried out under the most trying conditions. The total number of interruptions during 1889-90 amounted to 1840, lasting in all 34,409 hours, as against 1,903 and 38,729 respectively for the previous year. Of these 1,840 interruptions, 222, or 12 per cent. were due to storms; 59, or 3 per cent., to floods; 42, or 2·3 per cent., to lightning; 440, or 24 per cent., to birds, animals, and falling trees; and 148, or 8 per cent., to "*malice prepense.*" The interruptions due to floods, although comparatively few in number, were serious as to duration, amounting to 2,483 hours, or over 7 per cent. of the total. The number of telegraph offices open to the public is now 2,935, as against 2,740 in the previous year, increase 7 per cent. The total number of telegrams transmitted during 1889-90, including Government and international messages, amounted to 3,132,571, as against 2,982,152 for the preceding twelve months, an increase of 5 per cent. Government messages, inland and international, amounted to 16 per cent. of the total number transmitted, and their productive value to 20 per cent. of the total value. The general tendency is for the numerical percentage of Government messages to slightly increase, and for their average length to rapidly diminish. Inland telegrams, which form 70 per cent. of the total, only increased by 2·58 per cent. in number, and by 2·1 per cent. in value, in 1889-90. The custom of sending "deferred" telegrams tends to increase, nearly half of the private telegrams now being in this category. Nearly 72,000 telegraphic money orders were despatched during 1889-90, the increase over the preceding year amounting to 22 per cent.

Balata.—An exhaustive report on balata, or chicle gum, has recently been drawn up by Mr. G. S. Jenman, Government Botanist and Superintendent of the Botanic Gardens in British Guiana. The bullet-tree, from the bark of which balata is obtained, is a large forest tree ranging from Jamaica and Trinidad to Venezuela and Guiana. The tree grows to a height of 120ft., and has a large, spreading head. The trunk is nearly cylindrical. The bark is about ½in. thick, with deep parallel fissures, an inch or so apart. The hard, reddish-coloured wood is one of the densest in the colony, and is used for all sorts of purposes where great strength and durability are required. Dr. Hugo Müller, in a report on the substance, says:—"It seems that balata is by no means neglected, and, in fact, it would find ready purchasers if more of it came to the market. It commands a higher price than gutta-percha. It is used in almost all cases in which gutta-percha is used, but, on account of its higher price, only for superior purposes. It seems that balata is treated by the manufacturers simply as a superior kind of gutta-percha, and, therefore, its name disappears when manufactured. Nevertheless, balata is distinctly different from gutta-percha, and this is especially manifested in some of its physical characters. For instance, it is somewhat softer at ordinary temperatures, and not so rigid in the cold. In one respect balata shows a very marked and important difference from gutta-percha, and that is its behaviour under the influence of the atmosphere; while gutta-percha, when exposed to light and air, soon becomes altered on the surface, and changed into a brittle resinous substance into which the whole of the mass is gradually converted in the course of time, balata, on the other hand, is but slowly acted upon under these circumstances. The electrical insulating quality of balata is said to be quite equal to that of gutta-percha." The price for pure milk is 4s. per gallon, or occasionally a dollar, and for clean, well dried balata, 1s. per pound. The yield of a tree varies according to circumstances. If favourable, a tree 15in. to 20in. in diameter, bled 8ft. high, will yield three pints of milk.

The Electrical Engineering Department of Cornell University.—At the time of its erection in 1883, Franklin Hall (Cornell University) says the *Electrical Engineer* of New York, which was designed as a physical and chemical laboratory combined, was deemed ample for the accommodation of both departments. At the present time, however, the entire building is given over to the study of experimental physics. Research is regarded as a very important feature of the work of the department, and it forms an essential element in the training of all advanced students in physics. Such students come to it well equipped after a year of lectures and recitations, a year in the junior laboratories, and a year of more difficult work in heat and applied electricity. At the head of the department is Prof. E. L. Nichols. The dynamos that are used for University lighting are arranged to be operated with the greatest economy, as well as to afford opportunity for complete "plant" testing by students of electrical engineering. They have been placed in the steam engine laboratory in the closest proximity to the sources of water and steam power. The dynamos are so installed that they may be driven by water or steam power, or both. Ordinarily they are operated by water power, furnished by the turbine water wheel in the Ithaca Gorge. The dynamo room, which is in charge of Prof. H. J Ryan, is believed to be the largest college dynamo room in the United States, if not in the world. It contains no machines that are used in regular lighting service, but is devoted entirely to the experimental study of dynamos and motors. The floor space is 40ft. by 70ft. The collection includes nearly all the well-known commercial types, together with many machines of unusual form, constructed especially for experimental purposes. These machines are of various sizes, from 20 H.P. down, and they are arranged with special reference to the requirements of

Digitized by Google

experimental work. The measurement of current and electromotive force, together with a detailed study of storage batteries, arc lamps, voltmeters and electric meters, is carried on in a substantial one-storey building 100ft. by 37ft. Operations of extreme precision are conducted in the Magnetic Observatory, an isolated building entirely free from iron, which contains the great galvanometer and other standard instruments for measuring current and potential, and the magnetic elements.

Test of the Power Plant of the Utica (N.Y.) Electrical Belt Line Railway.—This company, says Messrs. O. G. Heilman and H. B. Clarke in the Cornell *Crank*, operates 26 miles of road. The power station is situated outside the city limits, at a distance of about two miles from the business centre. The steam plant consists of three 200 H.P. Armington and Sims cross compound engines. In the generation of electricity, six Thomson-Houston dynamos are in use, two being driven from each engine. Two runs were made, a preliminary run on May 2nd of five hours' duration, and the main test on the following day of 10 hours, readings being taken from 9 a.m. until 7 p.m. The feed water was measured by means of two calibrated barrels, one being filled while the other was emptying, and then reversing the process. Although the quantity of water required was large, by the use of this method no difficulty was experienced in keeping the supply equal to the demand. The injection water for the condenser was drawn from a pond near by, and after passing through the system was again returned to the pond through a sluice of rectangular section. The quantity of flow was obtained by placing a weir in the sluice, and the height of flow over the weir was measured by a hook gauge. The weight of coal consumed was determined in the usual manner, a Fairbanks scale being placed in the boiler room, and loads of 200 pounds each were dumped in front of the boiler at a time. The ash pits were cleared at the end of the test, and the ashes placed in the barrow and weighed. Electrical readings of current and voltage were taken every five minutes during the test. Below are tabulated some of the more important results.

Duration of test	10 hours.
Fuel burned	7,000 pounds.
Total ash	988 ,,
Moisture in 100lb.	8 ,,
Weight of combustible	5,452 ,,
Efficiency of combustion	82·15 per cent.
Kind of coal.	One-third bit slack and two-thirds anthracite culm.
Fuel per square foot of grate per hour	11·60 pounds.
Combustible per square foot grate per hour	9·087 ,,
Total water supplied	49,355·4 ,,
Average steam pressure (absolute)	138·8 ,,
Revolutions of engine	261
Average indicated horse-power	190 53
Coal per indicated horse-power per hour	3·5 pounds.
Water per indicated horse-power per hour (without charging condenser)	21·72 pounds.

$$\text{Average efficiency} = \frac{\text{Average electrical horse power}}{\text{Average indicator horse power}} = 81 \text{ per cent.}$$

Electric Lighting in Chicago.—A recent issue of *Engineering* contains a brief account of the rise and progress of municipal electric lighting in Chicago. In 1883 the Common Council of the city passed an ordinance requiring all electric conductors to be placed underground; the various companies doing business in the city, after exhausting all means to evade the ordinance, adopted various systems for placing their wires underground, viz., Dorsett conduit, Johnstone conduit, iron pipe, wooden boxes in which cable was placed, and the space between the box and cable filled with bituminous concrete; also conduits of creosoted wood and vitrified sewer pipe. Up to date these companies have placed underground 75 miles of conduit and about 7,000 miles of wire; the wire so placed underground embraces all branches of service, viz., telegraph, telephone, police, fire alarm, electric lighting, &c. In 1887 the city of Chicago erected 105 arc lamps of 2,000 c.p. on the bridges, viaducts, and street ends abutting the Chicago River. In 1889 it was decided to light the entire city by electric light, and to this end the city was divided into 12 electric light districts; each district was to have a power station located as near the centre as possible. In accordance with this plan power stations have been built in four districts. They are designed to accommodate the machinery necessary to operate 1,000 arc lights. The engines used are all of 125 H.P. The dynamos vary in capacity from 30 to 60 lights; they are belted direct to the engines. The conduits are of various construction, and include iron pipe laid in earth without other protection; iron pipe laid in concrete; iron pipe laid under the sidewalk space against the area wall; iron pipe, cement lined, laid in concrete. Five different sizes and manufacture of cable are used—viz., Patterson, Cobb vulcanite, standard underground, okonite, and kerite. The three former are lead cased, the latter two are taped. In contracting for the electric light cables a guarantee was required that the insulation resistance should not be less than 500 megohms per mile, and that they should not materially deteriorate for the space of two years after being in service. The electric light post used consists of a hollow iron base extending from the sidewalk to a height of 7ft. A hollow wooden pole extends through the iron base to a height of 9ft. above the base. The hollow space between the iron and wooden pole offers a receptacle not only for an electric light switch and fire-alarm box, where the latter is needed, but if in the future the city should need incandescent lights for city or private use there is room for a converter. The city of Chicago is now operating 929 arc lamps of 2,000 c.p. for illuminating its streets. Its electric light underground system comprises 169 miles of electric light cable.

Rope Driving.—In a Paper read at the Richmond Meeting of the American Society of Mechanical Engineers, Mr. C. W. Hunt says:—"The transmission of power by cotton or manilla ropes was a few years ago an experiment. It passed the experimental stage, and its use has spread with remarkable rapidity both in England and the United States, and promises, at the present rate of increase, to become a formidable competitor with gearing and leather belting for use where the amount of power is large or the distance between the power and the work is comparatively great. In many of the early applications so great a strain was put upon the rope that the wear was rapid. Installations which have been successful, as well as those in which the wear of the rope was destructive, indicate that 200lb. on a rope 1in. in diameter is a safe and economical working load. This makes the normal working load equal to one-thirty-sixth of the breaking strength and about one-twenty-fifth of the strength at the splice. The actual loads are ordinarily much greater, owing to the vibrations in running, as well as from imperfectly adjusted tension mechanism. At a speed of about 80ft. per second the centrifugal force increases faster than the power from increased velocity of the rope, and about 140ft. per second equals the assumed allowable tension of the rope. Computing this force at various speeds and then subtracting it from the assumed maximum tension, we have the force available for the transmission of power. The whole of this force cannot be used, because a certain amount of tension on the slack side of the rope is needed to give adhesion to the pulley. What tension should be given to the rope for this purpose is uncertain, as there are no experiments which give accurate data, and at the present time a decision must be made partly from analogy and partly from experience. The first cost of the rope will be smallest when the power transmitted by it is greatest, and, under the assumed conditions, will be a minimum for a given power when the velocity of the rope is about 80ft. per second. The ratio of the first cost of the rope running at any other speed will be—

$$\text{Ratio of first cost} = \frac{\text{H.P. at 80ft. per second}}{\text{H.P. at required speed}}.$$

The wear of the rope is both internal and external; the internal is caused by the movement of the fibres on each other, under pressure in bending over the sheaves, and the external is caused by the slipping and the wedging in the grooves of the pulley. Both of these causes of wear are, within the limits of ordinary practice, assumed to be directly proportional to the speed. If we divide the value for wear at a given speed by the horse-power that the same rope will transmit at other speeds, we get the relative wear of the rope in transmitting 1 H.P. The higher the speed, up to about 80ft. per second, the more power will be transmitted, but it is accompanied by a more than equivalent wear."

ELECTROMAGNETIC THEORY.—XII.

BY OLIVER HEAVISIDE.

(*Continued from page 240.*)

§ 69. Passing to more practical and specialised forms of expression of the continuity of energy, it is to be observed first that we are not usually concerned with a resultant flux of energy from all causes, but only of the particular forms relating to the dynamical question that may be under consideration. Secondly, that it is convenient to divide the energy above denoted by T into different parts, denoting potential energy, and kinetic energy, and wasted energy. Thus we have the following as a practical form,

$$\mathbf{fq} + \text{conv}\,[\mathbf{A} + \mathbf{q}(U + T)] = Q + \dot{U} + \dot{T}, \quad . \quad (11)$$

where the terms in the square brackets indicate the energy flux, partly convective, with the factor $\mathbf{q}$, U being the density of potential energy, and T that of kinetic energy, and partly non-convective, viz., $\mathbf{A}$, which may be due to a working stress. Also $\mathbf{fq}$ is the activity of impressed force (here merely a translational force). Thus on the left side of equation (11) we have a statement of the supply of energy to the unit volume fixed in space. On the right side we account for it by the rates of increase of the stored potential and kinetic energy, and by Q, which means the rate of waste of energy in the unit volume. It is also stored, at least temporarily but not recoverably, so that we may ignore energy altogether after it is once wasted.

In place of the term $\mathbf{fq}$, in which the impressed force is translational, we may have other terms possessing a similar meaning, indicating a supply of energy from certain sources. These sources, too, may be not external, but internal or intrinsic, as for instance when there is a thermo-electric or voltaic source of energy within the unit volume considered.

Also, the terms $\mathbf{A}$, U, T, and Q may have to be split up into different parts, according to the nature of the dynamical connections. The important thing to be grasped is, that whenever we definitely localise energy we can obtain an equation showing its continuity in space and time, and that when we can only partially localise it, we can still, by proper devices, allow for the absence of definiteness. The equation is simply the equation of activity of the dynamical system, suitably arranged to show the flux of energy, and can always be obtained when the equations of motion are known and also the nature of the stored and wasted energies.

§ 70. Now, in the electromagnetic case, the "equations of motion" are the two circuital laws, and to form the equation of activity, we may multiply (1) by $(\mathbf{H} - \mathbf{h}_0 - \mathbf{h})$ and (2) by $\mathbf{E} - \mathbf{e}_0 - \mathbf{e})$ and add the results; or else multiply (3) by $(\mathbf{H} - \mathbf{h}_0)$ and (4) by $(\mathbf{E} - \mathbf{e}_0)$ and add the results. The equation of activity thus obtained has then to be dynamically interpreted in accordance with the principle of continuity of energy.

When the medium is stationary, there is no difficulty with the interpretation. We obtain,

$$\mathbf{e}_0\mathbf{J} + \mathbf{h}_0\mathbf{G} = Q + \dot{U} + \dot{T} + \text{div}\,\mathbf{W}, \quad . \quad . \quad . \quad (12)$$

where $\mathbf{W}$ is a new vector given by

$$\mathbf{W} = V(\mathbf{E} - \mathbf{e}_0)(\mathbf{H} - \mathbf{h}_0), \quad . \quad . \quad . \quad . \quad (13)$$

and U is the electric energy, T the magnetic energy, and Q the waste per unit volume.

On the left side of (12) is exhibited the rate of supply of energy from intrinsic sources. On the right side it is accounted for partly by the waste Q, and by increase of the stored energy U and T. The rest is exhibited as the divergence of the flux $\mathbf{W}$ given by (13). We conclude, therefore, that $\mathbf{W}$ expresses the flux of energy in the electromagnetic field when it is stationary.

This remarkable formula was first discovered and interpreted by Prof. Poynting [*Phil. Trans.*, 1884, Pt. 2], and independently by myself a little later. It was this discovery that brought the principle of continuity of energy into prominence. But it should be remembered that there is nothing peculiarly electromagnetic about a flux of energy. It is here made distinct, because the energy is distinctly localised in Maxwell's theory.

The flux of energy takes place in the direction perpendicular to the plane containing the electric and magnetic forces (of the field), say

$$\mathbf{W} = V\mathbf{E}_1\mathbf{H}_1, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (14)$$

if $\mathbf{E} = \mathbf{e}_0 + \mathbf{E}_1$; $\mathbf{H} = \mathbf{h}_0 + \mathbf{H}_1$.

The formula is not a working formula, in general, for to know $\mathbf{W}$ we must first know the distribution of the electric and magnetic forces. But it is a valuable and instructive formula for all that. Its discovery furnished the first *proof* that Maxwell's theory implied that the insulating medium outside a conducting wire supporting an electric current was the medium through which energy is transferred from its source at a distance, provided that we admit the postulated storage of energy. For inside a wire the electric force is axial, and the magnetic force circular about the axis; the flux of energy is therefore radial. When the current is steady, it comes from the boundary of the wire, and ceases at its axis. It delivers up energy on the way, which is wasted in the Joule-heating. But when the current is not steady, the magnetic and electric energy will be also varying.

If we work out the distributions of electric and magnetic force outside the wire, according to the conditions to which it is subjected and its environment, we can similarly fully trace how the energy is supplied to the wire from its source. It is passed out from the source into the dielectric medium, and then converges upon the wire where it is wasted. The flux of energy usually takes place nearly parallel to the wire (because the electric force is nearly perpendicular to its boundary); its slight slope towards the wire indicates its convergence thereupon. If the wire had no resistance, there would be no convergence of energy upon it, the flux of energy would be quite parallel to it. Details are best studied in the concrete application, and it is only by the consideration of variable states, and the propagation of electromagnetic waves, that we can obtain a full understanding of the meaning of $\mathbf{W}$ considered as a flux of energy.

In the case of a simple progressive plane wave disturbance, in which a distribution of $\mathbf{E}$ and $\mathbf{H}$ (mutually perpendicular) in the plane of the wave is propagated unchanged through a medium at constant speed, it is a self-evident result that the energy of the disturbance travels with it. The flux of energy is, therefore (since $\mathbf{e}_0 = 0$, $\mathbf{h}_0 = 0$),

$$\mathbf{W} = \mathbf{v}\,(U + T) = V\mathbf{E}\mathbf{H}, \quad . \quad . \quad . \quad . \quad (15)$$

where $\mathbf{v}$ is the velocity of the wave, and U, T are the densities (which are here equal) of the electric and magnetic energies. In this example, which is approximately that of radiant energy from the sun, the idea of a flux of energy, and the conclusion that its proper measure is the density of the energy multiplied by the wave velocity, are perfectly plain and reasonable. Now, many cases of the propagation of waves along wires can be reduced to this simple case, with a correction for the resistance of the wire, and other cases can be represented by two or more oppositely travelling plane disturbances. In a very complex electromagnetic field, the flux of energy is necessarily also very complex, and hard to follow; but the fundamental principles concerned are the same throughout.

The flux of energy $\mathbf{W}$ arises from the internal structure of the ether. It is somewhat analogous to the activity of a stress. But the only dynamical analogy that is satisfactory in this respect is that furnished by Sir W. Thomson's rotational ether, when interpreted in a certain manner, so that $2\mathbf{E}$ shall represent a torque, and $\mathbf{H}$ the velocity of the medium, with the result that (on this understanding) $V\mathbf{E}\mathbf{H}$ is the flux of energy, whilst U is the potential energy of the rotation, and T the kinetic translational energy. But it is very difficult to extend this analogy to include electromagnetic phenomena more comprehensively. [*See* Appendix at the end of this chapter.]

§ 71. Passing now to the case of a moving medium, we shall obtain, from equations (1), (2), § 66, the equation of activity,

$$(\mathbf{e}_0 + \mathbf{e})\mathbf{J} + (\mathbf{h}_0 + \mathbf{h})\mathbf{G} = \mathbf{E}\mathbf{J} + \mathbf{H}\mathbf{G} + \text{div}\,V(\mathbf{E} - \mathbf{e}_0 - \mathbf{e})(\mathbf{H} - \mathbf{h}_0 - \mathbf{h}). \quad (16)$$

Or from equations (3), (4), § 66, we may get the form

$$\mathbf{e}_0\mathbf{J}_0 + \mathbf{h}_0\mathbf{G}_0 = \mathbf{E}\mathbf{J}_0 + \mathbf{H}\mathbf{G}_0 + \text{div}\,V(\mathbf{E} - \mathbf{e}_0)(\mathbf{H} - \mathbf{h}_0), \quad (17)$$

Digitized by Google

and from these a variety of other forms may be derived. The dynamical interpretation in accordance with the principle of continuity of energy is not so easy as in the former case. I have recently given a full discussion of these equations in another place. The following gives an outline of the results.

Since there is a flux of energy when the medium is stationary, there will still be a flux of this kind (*i.e.*, independent of the motion) when it is moving, whatever other flux of energy there may then be. I conclude that the Poynting flux **W** still preserves the form

$$\mathbf{W} = \mathrm{V}(\mathbf{E} - \mathbf{e}_0)(\mathbf{H} - \mathbf{h}_0), \quad . \quad . \quad . \quad . \quad (18)$$

from the fact that disturbances are propagated through a medium endowed with a uniform translational motion in the same manner as when it is at rest. Otherwise we could only know that it must reduce to this form when at rest.

Next, there is the convective flux of energy

$$\mathbf{q}(\mathrm{U} + \mathrm{T}), \quad . \quad . \quad . \quad . \quad . \quad . \quad (19)$$

where **q** is the velocity of the medium.

Thirdly, there is a flux of energy representing the activity, **A**, of the electromagnetic stress. It is given by

$$\mathbf{A} = -[\mathrm{V}\mathbf{e}\mathbf{H} + \mathrm{V}\mathbf{E}\mathbf{h} + \mathbf{q}(\mathrm{U} + \mathrm{T}]. \quad . \quad . \quad (20)$$

Fourthly, there is, in association with this stress, a convective flux of other energy, say,

$$\mathbf{q}(\mathrm{U}_0 + \mathrm{T}_0). \quad . \quad . \quad . \quad . \quad . \quad . \quad (21)$$

The complete flux of energy is the sum **X**, of these four vectors, *i.e.* :—

$$\mathbf{X} = \mathbf{W} + \mathbf{q}(\mathrm{U} + \mathrm{T}) + \mathbf{A} + \mathbf{q}(\mathrm{U}_0 + \mathrm{T}_0), \quad . \quad . \quad (22)$$

W and **A** being given by (18) and (20).

Finally, the activity of the intrinsic forces is

$$\mathbf{e}_0\mathbf{J}_0 + \mathbf{h}_0\mathbf{G}_0, \quad . \quad . \quad . \quad . \quad . \quad (23)$$

so that $\mathbf{J}_0$ is the true electric current.

We, therefore, have the equation of activity brought to the standard form

$$\mathbf{e}_0\mathbf{J}_0 + \mathbf{h}_0\mathbf{G}_0 = (\mathrm{Q} + \dot{\mathrm{U}} + \dot{\mathrm{T}}) + (\mathrm{Q}_0 + \dot{\mathrm{U}}_0 + \dot{\mathrm{T}}_0) + \mathrm{div.}\,\mathbf{X}, \quad (24)$$

which is a special form of equation (11), with the convergence of the energy flux in it replaced by its divergence (the negative of convergence) on the other side of the equation.

But the unknown terms, on the right side of (24), with the zero suffix, may be entirely eliminated, including those in **X**, by making use of the secondary equation of translational activity

$$\mathbf{F}\mathbf{q} = \mathrm{Q}_0 + \dot{\mathrm{U}}_0 + \dot{\mathrm{T}}_0 + \mathrm{div.}\,\mathbf{q}(\mathrm{U}_0 + \mathrm{T}_0), \quad . \quad . \quad (25)$$

where **F** is the translational force due to the stress.

When this in done, equation (24) takes the form

$$\mathbf{e}_0\mathbf{J}_0 + \mathbf{h}_0\mathbf{G}_0 = \mathrm{Q} + \dot{\mathrm{U}} + \dot{\mathrm{T}} + \mathbf{F}\mathbf{q} + \mathrm{div.}[\mathbf{W} + \mathbf{A} + \mathbf{q}(\mathrm{U} + \mathrm{T})] \quad (26)$$

where the energy flux represented includes the Poynting flux, the stress flux, and the convective flux of electric and magnetic energy.

We may observe that in the expression (20) for **A** occurs the term $-\mathbf{q}(\mathrm{U} + \mathrm{T})$, so that this term may be eliminated from (26), making the energy flux in it become

$$\mathrm{V}(\mathbf{E} - \mathbf{e}_0)(\mathbf{H} - \mathbf{h}_0) - \mathrm{V}\mathbf{e}\mathbf{H} - \mathrm{V}\mathbf{E}\mathbf{h}, \quad . \quad (27)$$

But these changes, with a view to the simplification of expression, cause us to altogether lose sight of the dynamical significance of the equation of activity, and of the stress function. Equation (26) is, therefore, the best form.

It should be understood that it is an identity, subject to the two laws of circuitation and the distribution of energy according to that of **E** and **H** in the field. But it should be also mentioned that in the establishment of (26) it has been assumed that the medium, as it moves, carries its intrinsic properties of permittivity and inductivity with it unchanged. That is, these properties do not alter for the same portion of the medium, irrespective of its position, although within the same unit volume these properties may be changing by the exit of one and entry of another part of the medium of different permittivity and inductivity; understanding by "medium" whatever is supporting the fluxes, whether matter and ether together, or ether alone; and it is also to be understood that the three velocities **q**, **u**, and **w** are identical, or that electrification which is always found associated with matter, moves with the medium, which is then the matter and ether, moving together. In other respects equation (26) is unrestricted as regards either homogeneity and isotropy in respect to permittivity, inductivity, and conductivity (electric, and fictitious magnetic).

Whether, when matter moves, it carries the immediately surrounding ether with it, or moves through the ether, or only partially carries it forward, and what is the nature of the motion produced in the ether by moving matter, are questions which cannot be answered at present. Optical evidence is difficult of interpretation, and conclusions therefrom are conflicting.

But in ordinary large scale electromagnetic phenomena, it can make very little difference whether the ether moves or stands stock-still in space. For the speed with which it propagates disturbances through itself is so enormous that if the ether round a magnet were stirred up, artificially, like water in a basin, with any not excessive velocity, the distortion in the magnetic field produced by the stirring would be next to nothing.

Strictly speaking, when matter is strained its elastic and other constants must be somewhat altered by the distortion of the matter. The assumption, therefore, that the permittivity and inductivity of the same part of the medium remain the same as it moves is not strictly correct. The dependence of the permittivity and inductivity on the strain can be allowed for in the reckoning of the stress function. This matter has been lately considered by Prof. Hertz. But the constants may also vary in other ways. It is unnecessary to consider here these small corrections. As usual in such cases, the magnitude of the expressions for the corrections is out of all proportion to their importance, in relation to the primary formula to which they are added.

§ 72. From the form of the expression for **A** in equation (20), viz., the flux of energy due to the stress, we may derive the expression for the electromagnetic stress itself. If the stress were of the irrotational type considered in works on Elasticity, we could do this by means of the formula (10), § 68. But for a stress of the most general type the corresponding formula is

$$\mathbf{A} = -\mathbf{Q}_q q, \quad . \quad . \quad . \quad . \quad . \quad . \quad (28)$$

where $\mathbf{Q}_q$ is the stress vector conjugate to $\mathbf{P}_q$; these are identically the same when the stress is irrotational. This gives

$$\mathbf{Q}_N = \mathbf{D}.\mathbf{E}\mathbf{N} + \mathbf{B}.\mathbf{H}\mathbf{N} - \mathbf{N}(\mathrm{U} + \mathrm{T}), \quad . \quad (29)$$

from which we obtain $\mathbf{P}_N$ by merely exchanging **E** and **D**, and **H** and **B**; thus

$$\mathbf{P}_N = \mathbf{E}.\mathbf{D}\mathbf{N} + \mathbf{H}.\mathbf{B}\mathbf{N} - \mathbf{N}(\mathrm{U} + \mathrm{T}). \quad . \quad . \quad (30)$$

This is the stress vector for any plane defined by **N**, a unit vector normal to the plane.

But it is only in eolotropic bodies that we have to distinguish between the directions of a force and of the corresponding flux. Putting these on one side, and considering only ordinary isotropy, the interpretation is simple enough. It will be observed that the electromagnetic stress (30) divides into an electric stress

$$\mathbf{E}.\mathbf{D}\mathbf{N} - \mathbf{N}.\tfrac{1}{2}\mathbf{E}\mathbf{D}, \quad . \quad . \quad . \quad . \quad . \quad (31)$$

and a magnetic stress

$$\mathbf{H}.\mathbf{B}\mathbf{N} - \mathbf{N}.\tfrac{1}{2}\mathbf{H}\mathbf{B}. \quad . \quad . \quad . \quad . \quad . \quad (32)$$

To find their meaning, take **N** in turns parallel to and perpendicular to the force **E** (or to **D**, since its direction is the same).

In the first case, the stress (31) becomes

$$\mathbf{N}(\mathbf{E}\mathbf{D} - \tfrac{1}{2}\mathbf{E}\mathbf{D}) = \mathbf{N}.\tfrac{1}{2}\mathbf{E}\mathbf{D} = \mathbf{N}\mathrm{U},$$

indicating a tension parallel to the electric force of amount U per unit area.

In the second case, when **N** is perpendicular to **E**, we have $\mathbf{D}\mathbf{N} = 0$, so that the stress is

$$-\mathbf{N}\mathrm{U},$$

that is, a pressure of amount U. This applies to any direction perpendicular to **E**, so that the electric stress consists of a tension U parallel to the electric force, combined with an equal lateral pressure.

Similarly the magnetic stress consists of a tension T parallel to the magnetic force, combined with an equal lateral pressure.

Digitized by Google

It will also be found that the tensor of the electric stress vector is always U, and that of the magnetic stress vector is always T. The following construction (Fig. 5) is also useful:—

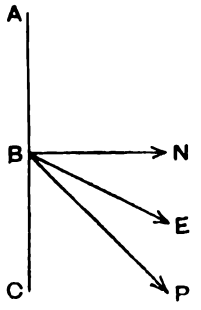

Fig. 5.

Let ABC be the plane on which the electric stress is required, BN the unit normal, BE the electric force, BP the stress. Then **N**, **E**, and **P** are in the same plane, and the angle between **N** and **E** equals that between **E** and **P**. Or, the same operation which turns **N** to **E** also turns **E** to **P**, except as regards the tensor of **P**.

To show the transition from a tension to an equal pressure, imagine the plane ABC to be turned round, and with it the normal **N**. Of course **E** remains fixed, being the electric force at the point B. Start with coincidence of **N** and **E**. Then **P** also coincides with them, and represents a normal pull on the surface A B C. As **N** and **E** separate, so do **E** and **P** equally, so that when **E** makes an angle of 45° with **N** the normal pull is turned into a tangential pull, or a shearing stress, **P** being now at right angles to **N**. Further increase in the angle **E** makes with **N** brings BP to the other side of BC; and when **E** is at right angles to **N**, we have **P** and **N** in the same line, but oppositely directed. That is, the tension has become converted into an equal pressure.

(To be continued.)

EXPERIMENTS ON THE ELECTRIC DISCHARGE IN VACUUM TUBES.

The beautiful and suggestive experiments on the electric discharge in vacuum tubes, shown by Prof. J. J. Thomson on the occasion of the visit of the Physical Society to Cambridge, in May, have excited considerable attention, and the illustrated account of them, which appeared in *The Electrician* of May 22nd, has been widely reproduced both in America and in France. In America the publication of Prof. Thomson's experiments has resulted in some interesting contributions to the *Electrical Engineer* of New York, by Prof. Elihu Thomson and Mr. Nikola Tesla, who appear to have been pursuing the same fruitful line of research. The *raison d'être* and the practical bearing of the phenomena described are not as yet apparent, but they seem to be of the order likely to yield valuable results both to the devotee of pure science and the patentee; indeed, Mr. Nikola Tesla has already brought the results of some of those striking experiments of his recently made public within the cognisance of the American Patent Office. However simple the future explanation, and however far-reaching the possible practical applications of these phenomena may be, they appeal at present mainly to the students of pure science, and to them the following notes by Prof. Elihu Thomson and Mr. Nikola Tesla will be of interest:—

"I have been much interested," says Prof. Elihu Thomson, in the *New York Electrical Engineer* of June 24th, "in the account of novel phenomena given under the title 'Some Experiments on the Electric Discharge in Vacuum Tubes,' by Prof. J. J. Thomson, inasmuch as several months ago I tried the same, or a very similar, experiment. Briefly, my experiment was performed with a closed ring made of a glass tube about one inch in diameter, the external diameter of the ring being about six inches. This was exhausted and laid alongside of a single turn of heavily insulated wire, which formed part of the discharge path from the outside of a Leyden jar, arranged to be charged and discharged rapidly by a Toepler-Holtz machine. It was found that at every discharge of the jar there was a discharge in the tube giving a band of light in the vacuous space. The accompanying engraving (Fig. 1) shows the arrangement of apparatus as just described. Curiously enough, the experiment of Prof. J. J. Thomson, in which a small pellet of mercury in an exhausted tube stopped the discharge, had its counterpart in my own experiments, as follows:—I had constructed a two-way discharge tube (Fig. 2). One branch, *a*, was large in diameter, and the branch *b* was of barometer-tube section. Wires sealed at *c*, *d* enabled a discharge to be passed. A small globule of mercury was placed in the tube, and could be shaken down into the barometer tube

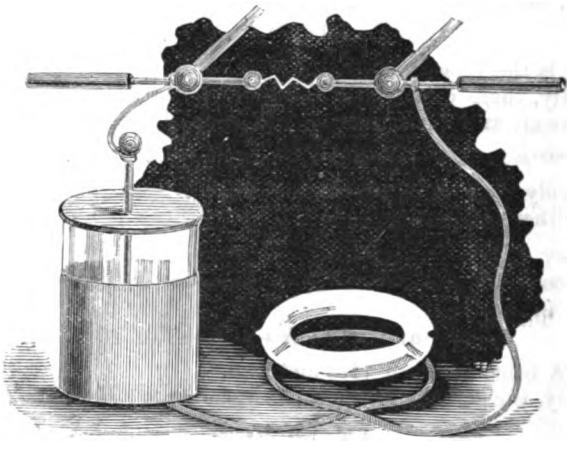

Fig. 1.

and out into the large tube at will. Though the discharge would not always divide and pass through both tubes from *c* to *d*, it sometimes did; but the interposition of the mercury globule in the small tube stopped the discharge through it.

Mr. Nikola Tesla, writing to the same journal (*Electrical Engineer of New York*, July 1), says:—"I have noted the description of some experiments of Prof. J. J. Thomson, on the 'Electric Discharge in Vacuum Tubes,' and in your issue of June 24th, Prof. Elihu Thomson describes an experiment of the same kind. The following lines are not penned with any desire on my part to put myself on record as one who has performed similar experiments, but with a desire to assist other experimenters by pointing out certain peculiarities of the phenomena observed, which, to all appearances, have not been noted by Prof. J. J. Thomson, who, however, seems to have gone about systematically in his investigations, and who has been the first to make his results known. These peculiarities noted by me would seem to be at variance with the views of Prof. J. J. Thomson, and present the phenomena in a different light.

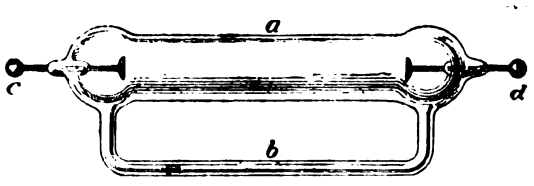

Fig. 2.

"My investigations occupied me principally during the winter and spring of the past year. During this time many different experiments were performed. Fig. 3 may serve as an example of one of the many forms of apparatus used. This consisted of a large glass tube, sealed at one end and projecting into an ordinary incandescent lamp bulb. The primary, usually consisting of a few turns of thick, well-insulated copper sheet, was inserted within the tube, the inside space of the bulb furnishing the secondary. This form of apparatus was arrived at after some experimenting, and was used principally with the view of enabling me to place a polished reflecting surface in the inside of the tube, and for this purpose the last turn of the primary was covered with a thin silver sheet.

Digitized by Google

"I have found that it is preferable to use in these experiments an alternate current machine, giving a moderate number of alternations per second, to excite the induction coil for charging the Leyden jar which discharges through the primary shown diagrammatically in Fig. 4, as in such case, before the disruptive discharge takes place, the tube or bulb is slightly excited and the formation of the luminous circle is decidedly facilitated. But I have also used a Wimshurst machine in some experiments.

"Prof. J. J. Thomson's view of the phenomena under consideration seems to be that they are wholly due to electro-magnetic action. I was, at one time, of the same opinion, but upon carefully investigating the subject I was led to the conviction that they are more of an electrostatic nature. In support of my view I will describe a few experiments

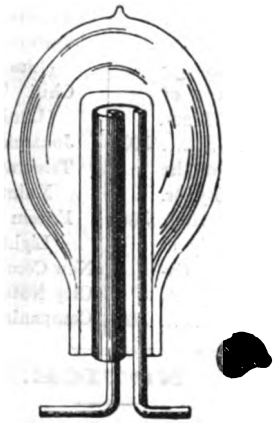

Fig. 3

made by me. To excite luminosity in the tube it is not absolutely necessary that the conductor should be closed. For instance, if an ordinary exhausted tube (preferably of large diameter) be surrounded by a spiral of thick copper wire serving as the primary, a feebly luminous spiral may be induced in the tube, roughly shown in Fig. 5. In one of these experiments a curious phenomenon was observed; namely, two intensely luminous circles, each of them close to a turn of the primary spiral, were formed inside of the tube, and I attributed this phenomenon to the existence of nodes on the primary. The circles were connected by a faint luminous spiral, parallel to the primary and in close proximity to it. To produce this effect I have found it necessary to strain the jar to the utmost. The turns of the spiral tend to close and form circles, but this, of course, would be expected, and does not necessarily indicate an electro-magnetic effect; whereas the fact that a glow can be produced along the primary in the form of an open spiral argues for an electrostatic effect.

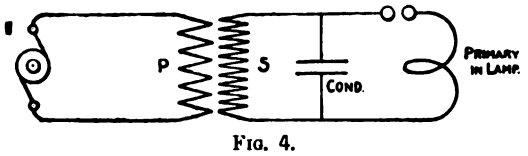

Fig. 4.

"Another experiment performed is illustrated in Fig. 6. In this case an ordinary lamp-bulb was surrounded by one or two turns of thick copper wire, P, and a luminous circle, L, excited in the bulb by discharging the jar through the primary. The lamp-bulb was provided with a tinfoil coating on the side opposite to the primary, and each time the tinfoil coating was connected to the ground, or to a large object, the luminosity of the circle was considerably increased. This was evidently due to electrostatic action.

"In other experiments I have noted that when the primary touches the glass the luminous circle is easier produced and is more sharply defined; but I have not noted that, generally speaking, the circles induced were very sharply defined, as Prof. J. J. Thomson has observed; on the contrary, in my experiments, they were broad, and often the whole of the bulb or tube was illuminated; and in one case I have observed an intensely purplish glow, to which Prof. J. J. Thomson refers. But the circles were always in close proximity to the primary, and were considerably easier produced when the latter was very close to the glass.

"Another observation made by me was that when the specific inductive capacity of the medium between the primary and secondary is increased, the inductive effect is augmented. I have likewise noted that when a bulb is surrounded by a wire closed upon itself and in the plane of the primary, the formation of the luminous circle within the bulb is not prevented. But if, instead of the wire, a broad strip of tinfoil is glued upon the bulb, the formation of the luminous band was prevented.

"Some of the experiments of Prof. J. J. Thomson also would seem to show some electrostatic action. For instance, in the experiment with the bulb enclosed in a bell jar, I should think that when the latter is exhausted so far that the gas enclosed reaches the maximum conductivity, the formation of the circle in the bulb and jar is prevented because of the space surround-

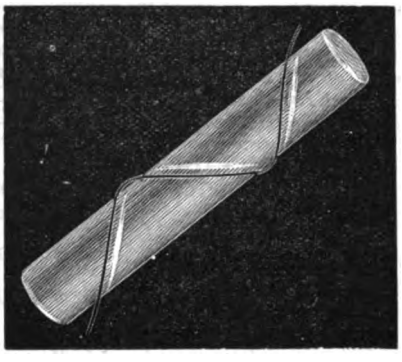

Fig 5

ing the primary being highly conducting; when the jar is further exhausted the conductivity of the space around the primary diminishes, and the circles appear necessarily first in the bell jar as the rarefied gas is nearer to the primary. But were the inductive effect very powerful they would probably appear in the bulb also. If, however, the bell jar were exhausted to the highest degree they would very likely show themselves in the bulb only—that is, supposing the vacuous space to be

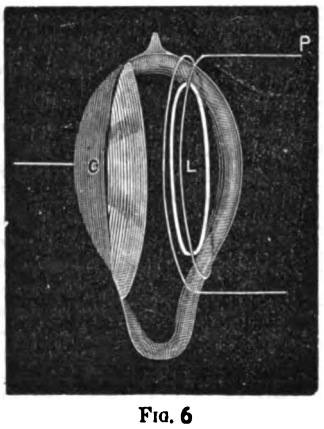

Fig. 6

non-conducting. On the assumption that in these phenomena electrostatic actions are concerned we find it easily explicable why the introduction of mercury or the heating of the bulb prevents the formation of the luminous band or shortens the after-glow; and also why, in some cases, a platinum wire may prevent the excitation of the tube. Nevertheless some of the experiments of Prof. J. J. Thomson would seem to indicate an electro-magnetic effect. I may add that in one of my experiments in which a vacuum was produced in the Toricellian method, I was unable to produce the luminous band, but this may have been due to the weak exciting current employed.

"My principal argument is the following: I have experimentally proved that if the same discharge which is barely sufficient to excite a luminous band in the bulb when passed through the primary circuit be so directed as to exalt the electrostatic inductive effect an exhausted tube, devoid of electrodes, may be excited at a distance of several feet."

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements should be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL PREPAID ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1891 Edition, published on the 23rd February, 1891, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with well-written Biographical Notices of leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1891 should be ordered at once. Price 5s., post free 5s. 9d. Abroad postage extra. Prospectuses free.

ELECTRICAL BOOKS AND PUBLICATIONS

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. Vol. I. Price 7s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Vol. I. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

Several Further Volumes in Active Preparation.

NOW READY, IN TWO VOLUMES.

"THE ELECTRICIAN" PRIMERS.

Fully Illustrated.

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

MORDEY-WILLANS COMBINATION RUNNING IN PARALLEL.

It is well known that certain alternate current dynamos will run in parallel with the greatest ease and certainty, while others cannot be made to get into step, or rather refuse to keep in step when they have been switched in together. Among the reasons which have been put forward with an endeavour to account for this obstinate behaviour, it has been suggested that almost all successful parallel running has hitherto been accomplished with belt or rope driven dynamos, and that at all events one failure of a most complete character was attributed to the fact that Willans engines were employed. It has further been alleged that the successful running of the alternators at Rome, where the machines are coupled direct to high speed horizontal engines, is to be attributed to the delicacy of the governors with which these engines are provided. Without entering on the thorny path of discussion of absolute priority, we may assert that it is generally acknowledged that, with the exception of an experiment at the North Foreland Lighthouse, several *obiter dicta* of a mathematical character, and some unpublished work at Rome, Mr. MORDEY first demonstrated in an engineering fashion the perfect feasibility of running alternators in parallel. It may be remarked, *en passant*, that the publication of Mr. MORDEY's experiments, while it set other manufacturers at work to imitate and reproduce them, after the fashion of Moses and the magicians, completely silenced the favourite cry of the low-pressure engineers who were wont to hold up the parallel running of continuous current dynamos as one of the important merits of their system.

It is hardly necessary to say that both MR. MORDEY and Messrs. WILLANS and ROBINSON declined to admit that there was

Digitized by Google

any truth in the suggestion to which we have referred. The former was so confident that his machines when once in step would keep in step, and would not be troubled by direct and rigid connection to an engine, and Mr. Willans being well justified in believing that he not only understood his own engine better than other engineers did, but that he, perhaps, knew even more about it than they knew about their own dynamos, afforded an opportunity for a practical test of the matter as soon as the question was raised by some probable purchasers of the combined machinery. On Tuesday last experiments were made at the engine works at Thames Ditton with two A. 9 Mordey alternators, each capable of an output of 50 H.P. at 666 revolutions per minute, the one being the machine commonly used for testing at the Lambeth Works; and the other a similar machine of an early pattern, used for occasional work. Two Willans engines, of their two-crank E size, were taken from stock, and were coupled direct to the dynamos. The governors were of the ordinary kind, simply taken from the stores, and used without any special adjustment. Neither the engines nor the dynamos were arranged specially for the work, nor were they suited for each other as regards output and speed. A pair of transformers were arranged in the usual way as a synchroniser, and a pair of lamps were placed in series with the secondary coils. The engines were started, and ran at about 472 revolutions per minute. Before attempting to switch them together, the great regularity of speed of the two engines, as shown by the synchronising lamps, was very remarkable. The lamps glowed and faded at first rapidly, and as soon as both stop valves were open, and the full-speed attained, it was possible, by adjusting the governor of one to slow down the synchronisms to less than four a minute, and one long glow taken at random timed 28 seconds. It was very easy to select the best moment for switching on, and this being done both at light load, half, and full load, the fact was proved, which, though perhaps a foregone conclusion, had not actually been proved before, that a flexible driving, by belt or other elastic connection is not only not necessary, but does not appear to offer any appreciable advantage, except in cases where the speed of the engine is very irregular during each revolution, owing to irregular turning moment. A load of about 36 kilowatts was put on, and the steam was shut off from one engine, leaving only about 5lb. to keep the connecting rod from lifting. The one machine took the load and drove the other as a motor, taking with it the engine, which requires about 25lb. of steam to move it. Some further experiments were carried out afterwards, to try the effect of a considerable resistance in the circuit connecting the two machines, and during these tests the switch was more than once intentionally pulled over a little before the moment when the lamps showed that the two machines were exactly in step, but the two armatures adjusted themselves instantly without any perceptible shock or noise.

We have recently discussed at some length some of the possible reasons why certain machines can be run together, and why others refuse to keep in step. These experiments remove one uncertainty in a most satisfactory and conclusive manner, and show that the difficulty is of a purely electrical nature, and depends probably on the presence of iron in the armature and the frequency of the alternations, because, at high frequencies, there is not time for the iron to respond to the pull. The Zipernowski dynamos run easily together with a frequency of 42, and the inventor says that he can run his dynamos in parallel with this frequency "easier and in a more simple manner than with a higher one," but he has mechanical reasons for not increasing the number of alternations. In stations where alternating dynamos are used which cannot run in parallel, the only way to ensure that each is fully loaded is to keep an incessant watch on the ammeters and to distribute the various circuits. When the load is rising and another machine has to be started, a number of partially loaded circuits must be put on, and as the current in these increases some must be taken off and given to the others. Constant watching and immediate attention are needed to ensure anything like a full load on every dynamo, and it is only when each engine is either well employed, or standing, that a satisfactory coal consumption can be arrived at. But such a station is at a disadvantage, and the imperfection of the system is felt both in the increased cost of attendance and in the continual blinking of the lights, though station attendants fondly imagine that they handle the switches with such dexterity that the consumers fail to notice these brief extinctions.

OBITUARY.

WILLIAM HENRY STONE.

We are sorry to record the death of Dr. William Henry Stone, at his residence, Geraldine-road, Wandsworth, in the 62nd year of his age. Dr. Stone was the son of the late Canon Stone of Canterbury, and was educated at Oxford, where he won an open scholarship at Balliol College, and took his degree in 1852. From Oxford he went up to St. Thomas's Hospital to study for the medical profession, and took the degree of M.B. at Oxford in 1856. He became Fellow of the Royal College of Surgeons in 1856, and of the Royal College of Physicians in 1863, and was Censor of the College in 1884. He was appointed Assistant Physician, and afterwards Physician, to St. Thomas's Hospital, and was for many years Lecturer on Physics at the same hospital. He was also Assistant Physician to the Consumption Hospital at Brompton, and Consulting Physician to the Clergy Mutual Insurance Company, and Superintendent and Inspector of the Board of Health, Trinidad. A severe illness some few years back compelled him to give up many of his active duties, and he was then appointed Consulting Physician to St. Thomas's Hospital, an honorary distinction which he enjoyed till his death. Dr. Stone's intellectual qualities were of a briliant order, and he was a sparkling and witty conversationalist, but his temperament could not endure the drudgery of private practice. His chief delight was in physical work and research, principally in the domains of Acoustics and Electricity. He was an excellent musician, and one of the very few amateurs who played in the Philharmonic and other first-rate orchestral concerts, generally playing the double-bassoon, an instrument which was practically his own invention. He was also the author of a book on Sound, and of another on the Scientific Basis of Music.

Dr. Stone will, however, be chiefly remembered in the electrical world by his experiments on the effects of electricity upon the human body, a line of research for which his training as a physician and as a physicist doubly fitted him.

In December, 1884, Dr. W. H. Stone exhibited before the Physical Society an ingenious tuning fork interrupter commutator. At the Southport meeting of the British Association in 1883, he gave a short account of some experiments which showed that the resistance of the living human body to electrical currents was considerably less than that then given in all works on medical electricity, and he returned to the subject at the Aberdeen meeting in 1885. In the spring of 1886 Dr. Stone delivered a series of three lectures on "The Electrical Conditions of the Human Body" before the Royal College of Physicians. Dr. Stone was unmarried, and spent the greater part of his income on physical apparatus for his own researches, and for illustrating experimentally his lectures at the hospital, which were consequently very popular with the students.

THE HISTORICAL DEVELOPMENT OF THE INDUCTION COIL AND TRANSFORMER.

BY DR. J. A. FLEMING, M.A.

(Continued from page 248.)

§ 13. **Ruhmkorff's Induction Coils.**—In 1851, M. Ruhmkorff, a skilful mechanician in Paris, profiting by the experiments of Masson and Breguet, and probably not aware of the researches of Callan and Page, addressed himself to the problem of increasing the spark-producing power of the induction coil, with the object of exalting the electrostatic effects which Masson and Breguet had produced. He paid the greatest attention to the insulation of the secondary coil, insulating the covered wire by passing it through melted shellac, and separating each layer of wire from the next by means of varnished silk or shellaced paper. He greatly lengthened the secondary circuit, employing in some coils five or six miles of secondary wire, and he insulated with care the primary from the secondary circuit by employing a glass tube on which to wind the secondary circuit, and glass cheeks to preserve the wire in place at the ends. He also supported the ends of the secondary wire on glass pillars. He provided, also, a simple form of current-reverser to change the direction of the primary circuit, and greatly improved the action of the vibrating hammer interrupter. The greatest service was, however, rendered by Fizeau by his application of the condenser (*Comptes Rendus*, 1853, Vol. XXXVI., p. 418), and Ruhmkorff carefully studied the appropriate dimensions of the condenser. This condenser he made at first of a sheet of oiled silk, covered on both sides with tinfoil; later he employed sheets of well-selected paper, carefully varnished, and coated with tinfoil on each side. This condenser was placed in the base of the induction coil, and the two terminals of the condenser connected to the two opposite sides of the "break" points. The condenser was made by varnishing close-grained but thin paper with shellac varnish. Each sheet was then examined for defects. A number of sheets of tinfoil were cut, each somewhat less in size than the sheets of varnished paper. A pile was made by building up alternate sheets of paper and tinfoil, placing each alternate sheet of tinfoil so as to protrude from the paper pile on opposite sides. The pile was then compressed, and all the tinfoil sheets on one side connected together, and also those on the other. Hence the arrangement formed a compact kind of Leyden jar, of which one set of tinfoil sheets formed the "outside" and the other set the inside surfaces, the varnished paper being the dielectric.* In the larger sized coils Ruhmkorff found it convenient to revert to the mercury-break of Page, and this was modified and re-invented by Foucault, who again suggested the advantages of making a break by withdrawing a steel or platinum point from a mercury surface, covered with alcohol or oil. Aided thus by Fizeau and Foucault, Ruhmkorff produced induction coils which enabled him to obtain secondary sparks several centimetres in length. It was, however, found that the tendency to internal sparking, and to rupture of the insulation of the secondary circuit, became very great when the coils were enlarged beyond a moderate size. In his later coils, after 1855, Ruhmkorff adopted a mode of construction which was suggested by Poggendorff, Stöhrer, and l'Abbé de la Borde, about 1854, viz., to wind the coil in sections so that no two portions of the wire which are closely adjacent are at very different potentials. When a coil is built up by winding layer over layer in the ordinary manner, the ends of the layers of wire, and particularly the similar ends of the first and last layers, are at very different potentials, and there is a great tendency for the discharge to pass between these points. In fact the sparking distance of the coil is limited by the distance of these portions of the wire. Under these conditions internal sparks were found to pass and to break down the insulation of the secondary circuit. The suggestion to wind the wire in separate partitions originally came from the English electricians, Edward and Charles Bright, who, in a patent taken out in 1852,* describe a method of thus winding electro-magnets, and in their fourteenth clause say, "The manner in which our fourteenth improvement may be carried into effect is as follows:—It is well known that the ordinary mode of winding the wire on coils is to wind it backwards and forwards upon the core. Our improved plan is to divide the core lengthways into compartments, by means of separating pieces fastened to the body of the coil, before winding and dividing the coil into compartments. In winding the wire, one end compartment is filled, and then the next, and so on." In adopting this method of winding, the flat coils of wire can be wound independently, and are then so joined up that the outside end of the wire on one coil is joined to the outside end of the wire of the next compartment, and yet the winding follows the same direction in each bobbin or separate flat coil. Hence no two portions of the wire at very different potentials are very close to each other, or, if they are, they are well insulated.

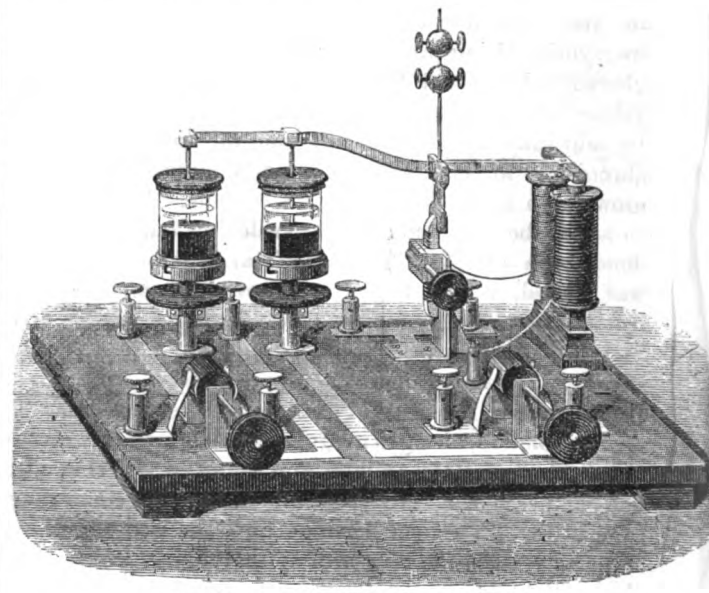

FIG. 22.—Ruhmkorff's Mercurial Break.

One of Ruhmkorff's largest coils made about 1867 was 52 centimetres in length, and the secondary circuit was divided into 80 flat coils or partitions, each compartment being occupied with five or six spirals—that is, being of a width equal to five or six times the diameter of the covered wire. The secondary circuit consisted of copper wire one-tenth of a millimetre in diameter, and 100,000 metres, or 62 miles, in length. The different compartments of the secondary circuit were insulated from one another with shellaced paper or varnished silk, and the different layers of wire in each compartment also insulated with shellac. The secondary circuit was wound upon a tube of glass as a support. The condenser employed with this coil was formed of 100 sheets of tin of a length of 50 centimetres and a breadth of 25 centimetres, insulated with paper covered with shellac, and formed a condenser having a total surface of about 12 square metres. The primary wire in this coil had a thickness of about three millimetres. This coil could give sparks 40 centimetres in length between the ends of the secondary circuit. The coil was usually worked by the current from six large Bunsen cells. For such large coils Ruhmkorff and Foucault found the

* The theory of the action of the condenser has been discussed in Vol. I. *Alternate Current Transformer*, § 7, Chap. V. When the contact breaker is provided with a condenser whose opposite surfaces are connected to the two sides of the break points, there are two distinct kinds of sparks observable at the break. There is first the spark at "break," due to the self-induction of the primary circuit, and there is the spark at "make," due to the discharge of the condenser. Rijke made the observation that the condenser is more effective in lengthening the secondary spark of the coil when the break points, or points of contact, are of gold, copper, or silver, than if they are of platinum. The discharge spark of the condenser, when a too small condenser is employed, is very bright and hot, and sometimes welds together the platinum contact points. The remedy for this accident when it occurs is to employ a condenser of larger capacity. Callan (*Phil. Mag.* [4] Vol. XIV., p. 337, 1857) suggested the employment of amalgamated copper contacts for the break, working in or smeared with oil to prevent oxidation and increase the suddenness of the break.

* British Specification, No. 14,331, of 1852.

Digitized by Google

hammer-break with platinum contacts quite unsuitable, since the contact points are rapidly burnt away by the spark at "break," due to the self-induction of the primary circuit, and by the additional spark at "make" of the contact, due to the discharge of the condenser. Hence they revived and improved the mercury break, covering the surface of the mercury with alcohol, and breaking the primary circuit (*see* Fig. 22) by a platinum point automatically lifted out of the mercury.*

§ 13a. Improvements on Ruhmkorff's Coils.—Ruhmkorff succeeded in producing induction coils capable of giving very long sparks from the secondary circuit, but the insulation of these coils was not always found to be permanent. Du Moncel tells us that Fizeau, in endeavouring to join up several Ruhmkorff coils with the secondary circuits in series, felt severely the need for better insulation, and that M. Jean, a simple amateur mechanician in Paris, solved the problem, in 1854, by plunging the whole coil beneath the surface of a liquid insulator, viz, oil of turpentine; and by constructing coils in this manner, insulated with a fluid insulation, Jean succeeded in getting sparks of 30 centimetres in length at a time when no one, at least in France, had approached this length.† Du Moncel says that these experiments of Jean were neglected or lost sight of, and that Ruhmkorff finally succeeded in obtaining sparks of 60 centimetres in length by building up the coil in sections. Jean's coils were built up as follows: The primary wire consisted of four layers of wire and the secondary circuit of 50 layers. The primary wire had a thickness of 1½ millimetres and the secondary ·25 millimetre. The different layers of the primary and secondary were separated from each other by well-dried blotting paper. The whole coil was placed in a glass vase and filled up with oil of turpentine. The ends of the secondary wire where they emerged from the liquid were passed through glass tubes. The whole coil was baked and dried to eradicate moisture previous to immersion in the insulating liquid. M. Jean even performed this desiccation in a vacuum, and, by taking the greatest pains to avoid contact of air after and during this drying process previous to placing it in the liquid, he obtained very extraordinary insulation. There can be little question that M. Jean was here on the right track, and that this liquid insulation had many important advantages.

§ 14. Poggendorff's Researches on Induction Apparatus.—In the *Philosophical Magazine* for July, 1855, is to be found a long Paper by Poggendorff, giving an account of his researches and suggestions with regard to the induction apparatus of Ruhmkorff. He begins by criticising the construction adopted by Ruhmkorff, as illustrated by one of his coils in the physical laboratory of the University of Berlin, and points out in the first place the defect we have already referred to in the original manner of winding the coil, and the advantages to be derived from winding the secondary coil in sections. With respect to the insulation of the wire, he advises, instead of shellac dissolved in alcohol, the use of an easily fusible insulator, such as spermaceti, or a mixture of wax and oil, or paraffin wax, or, better still, the use of a *fluid* insulator, such as vegetable oil, or oil of turpentine, so that permanent defects of insulation could not occur. He also proposed insulating the silk-covered wire by first boiling it in spermaceti to get rid of moisture and air. Poggendorff experimentally examined the construction of each element of the coil, with the object of ascertaining the best arrangement and proportions of each part. With respect to the condenser, he adopted a suggestion which apparently emanated from Halske—viz., to use mica for the dielectric, and he convinced himself of the great superiority of mica over oiled silk in this portion of the apparatus. Owing to the expense of procuring large sheets of mica, he also used very thin paper, varnished with amber varnish, as a substitute. Also he used thin gutta-percha sheet for the same purpose. Poggendorff made many experiments with the object of ascertaining the exact influence of the dimensions of the condenser upon the spark-producing power of given coils. He came to the conclusion that the stronger the primary current and the longer the primary circuit, the greater must be the capacity of the condenser in order to obtain the maximum possible secondary spark. Poggendorff established the following facts, some of which had previously been arrived at by Masson and Breguet:—

(i.) When the terminals of the secondary circuit are joined by a metallic wire, or other good conductor, induced currents at "break" and "make" of the primary circuit, which are in opposite directions, circulate in the secondary. These currents are equal in quantity, but different in electromotive force.

(ii.) If a good conducting electrolyte, such as dilute sulphuric acid, is introduced into the secondary circuit, oxygen and hydrogen are liberated at both poles of the voltameter.

(iii.) If the circuit of the secondary coil is interrupted by a thin stratum of air or gas so that the secondary circuit is not complete, then only one of the secondary currents passes, viz., that produced at the break of the primary circuit. Hence we have, then, phenomena of tension at the ends of the secondary circuit. If an electroscope is touched for a moment against one of the terminals of the secondary it will become charged, but the sign of that charge will be a matter of chance, depending on the instant when it was so touched. If, however, a spark is passed across an air-gap into the electroscope from either terminal of the secondary it will always give one kind of charge, viz., that due to the state of the secondary pole when the primary current is interrupted. The action of the condenser in strengthening the secondary current produced at the "break" of the primary is only seen when the circuit of the secondary circuit is interrupted by an air-gap or circuit of high resistance. When the secondary circuit is completed by a better conducting medium, such as a partially exhausted tube, the action of the condenser is much less apparent. Poggendorff also examined the phenomena presented when the currents from the secondary coil are employed to charge a Leyden jar. He noted the effects, independently observed by Sir W. Grove, and published by him in the *Philosophical Magazine* for January, 1855, which attend the secondary discharges when a discharging path is opened across the terminals of the condenser thus applied. Poggendorff states that, in December, 1854, he communicated to the Berlin Academy the observation that if a Leyden jar has its internal and external coatings connected respectively to the two terminals of the secondary coil, and if wires are also brought from the terminals of the secondary coil to within a short distance of each other, snapping, bright intermittent sparks will be obtained, quite different in appearance from the thin, bluish continuous sparks of the ordinary secondary discharge. *Cæteris paribus*, these discharge sparks are, according to Poggendorff, stronger the more powerful the battery, and the smaller the charged surfaces.

Grove discovered, quite independently of Poggendorff,* the effect produced by a Leyden jar connected across the secondary terminals, but he examined at much greater length the whole phenomenon. Briefly, he found it to be as follows:—If a Leyden jar has its outside coating connected to the inner end of the secondary circuit of an induction coil, and its inner coating to the outer end of that circuit, and if a pair of discharging points are connected across between the two coatings of the jar, then when the coil is set in action and the discharge points adjusted to a proper distance, loud, brilliant intermittent sparks jump across. These sparks are much more brilliant and solid than the ordinary discharge of the secondary circuit, and take place at a slightly less distance. If, now, the battery power or number of cells operating the coil is increased the effect is only to increase the sparks at the primary contact

* Foucault, *Comptes Rendus*, Vol. XLIII., p. 44, 1856.

† Jean's experiments are recorded in the *Comptes Rendus*, Vol. XLVI., p. 186, 1858. It is curious to observe that Du Moncel naturally claims priority for his countryman Jean with respect to this suggestion, to immerse the whole induction coil in oil or insulating fluid to obtain higher insulation, whilst Wiedemann (see *Galvanismus*, § 911) claims for Poggendorff the origination of the idea. Modern inventors have again become alive to the value of this suggestion, and patents have been taken out for immersing alternate current transformers in oil as a means of increasing the insulation. Mr. Brooks of late years has especially drawn attention to the use of certain oils as insulators and to the practical employment of them in cables for high pressure currents.

Digitized by Google

breaker, but not much to increase the secondary discharges. When, however, a larger Leyden jar, or another Leyden jar joined in parallel with the first, is taken and connected to the secondary the effect is immediately to decrease the primary spark and to increase the secondary spark. Hence Grove found that he could apparently go on adding cells to the battery producing this primary current, or increase the primary electromotive force and Leyden jars to the secondary circuit, or increase the capacity of the secondary circuit, over wide limits, and with each such addition the brilliancy and length of the discharges from the secondary terminal were increased. In seeking for an explanation of this effect we have to bear in mind that the Leyden jar or condenser which is joined across the secondary terminals acts as a conductor of electricity *during* the time in which the induced electromotive force in the secondary circuit is increasing in amount. Also, the capacity of the condenser reacts with the self-induction of the secondary circuit to increase the maximum potential difference at the terminals of the secondary coil in a manner to be discussed more fully later on. During the period of time in which the secondary inverse induced current is flowing into the condenser it is being charged. At the instant when the secondary induced electromotive force becomes zero the condenser begins to discharge. Owing, however, to the great self-induction of the secondary circuit of the coil the charge of this condenser does not flow back through the secondary coil, but springs across the parallel air gap, making a spark. The greater brilliancy and noise of this spark, as compared with the ordinary discharge of the secondary circuit, is due to the greater quantity of electricity which passes at each discharge. Poggendorff made some very instructive experiments with two or more induction coils,* which if they had been carefully studied by subsequent inventors might have done much to prevent misconception and error. Poggendorff took two similar induction coils, which we will call A and B, and arranged them with their primary coils *in series*. A was allowed to give sparks from its secondary circuit whilst the secondary circuit of B remained open and having its soft iron core removed. The introduction of the soft iron core into the primary coil of B at once weakened the sparks from the secondary circuit of A. Hence, says Poggendorff, it follows that "two complete instruments combined one after the other mutually disturb one another, and the total effect is not equal to the sum of the effects which each would produce with the same intensity of galvanic current."

He then modified the experiment by placing the coils A and B *alongside* of one another, so that the primary circuits were joined in parallel, and he found that the insertion of the soft iron core into B *increased* the sparks given by A. He found that in the first case, when the primaries were in series, the closing of the secondary circuit of B again reproduced the sparks at their former intensity at the secondary circuit of A; whilst, in the second case, when the primary circuits of the coils were in parallel, the subsequent closing of the secondary circuit of B destroyed the augmentation of the sparks at the secondary circuit of A. The explanation of these effects is obvious in the light of what is now known as to the effect of the closed secondary circuit upon the impedance of the primary circuit. When the primary coils were in series, the introduction of the iron core into B increased the impedance of the whole circuit, and hence decreased the primary current and the secondary sparks of A, but the subsequent closing of the secondary circuit of B partly annulled the impedance of the primary circuit, and hence reaugmented the secondary sparks of A. Similar explanations apply to the case of the coils with primaries in parallel. If these experiments had been carefully considered by subsequent inventors it would have been seen that induction coils with their primaries in series are not independent of each other, and that the strength of the primary current is affected by the opening or closing of the secondary circuit of any one of them. Poggendorff examined very carefully the action of the contact breaker, both when operating in air, as well as when immersed in various liquids, and also when in a good vacuum. He found that, when the contact points of the contact breaker were immersed in pure distilled water or alcohol, the length of the secondary spark was augmented, when compared with its length, when the contact breaker operated in air. He made also the curious observation that when the contact breaker on the primary circuit operated in a good vacuum its action in lengthening the secondary spark was so much increased that it produced very nearly the same effects when acting without a condenser as did a contact breaker provided with a condenser when acting in air.

NOTE ON THE DECREMENT OF ELECTRIC OSCILLATIONS.*

BY M. V. BJERKNESS.

The law of damping, governing the oscillations of electricity in a Hertz vibrator, can be determined in a simple manner when the two following suppositions are made:—

1. The movement of electricity in the resonator is of a simple harmonic character, like that of the bob of a pendulum when under the action of a periodic force.

2. The decrement of the oscillations in the vibrator is considerably greater than that in the resonator.

On these assumptions, the intensity of the oscillations in the resonator can be calculated as a function of the ratio of the periods of the vibrator and resonator. Sufficient indication of the method of calculation will be found in Note 5 of the recent work of M. Poincaré, entitled "Electricité et Optique." In the formula there exists only one unknown quantity—the decrement of the oscillations aroused by the vibrator—and this constant has been determined by M. Bjerkness with the aid of a series of nine resonators, whose periods varied between 0·87 and 1·13 times the period of the vibrator.

The chief result of the research is as follows:—A vibrator producing oscillations having a wave length of 4·5 metres had a logarithmic decrement equal to 0·26, so that the ratio of the amplitudes of two successive elongations in the positive direction was equal to 0·77. After twenty oscillations the electrical movements were thus negligibly small, and the phenomena could not last longer than about a millionth of a second. The spark gap was from 1 to 2 mm. in length. If it was increased the decrement was found to increase, and analogous effects could be obtained experimentally by various arrangements of the apparatus, so that the decrement could not be regarded as a constant quantity.

The value found for the logarithmic decrement of the resonator was 0·002. This number must only be regarded as a rough approximation, as the properties of the secondary spark are not well enough known for accurate calculation. A comparison of this quantity, with the corresponding number found for the vibrator, affords, however, a satisfactory confirmation of supposition (2.) given above.

The decrement of the oscillations emitted by the vibrator is so rapid that some important conclusions necessarily follow. If the waves are reflected perpendicularly at a surface, so as to retrace their former course, the interference which takes place will be the result of superposing a weak wave on a more powerful one. There will not be nodes and loops in the ordinary sense, and at a distance of some wave lengths from the mirror the differences between the maxima and minima become insensible.

Elementary reasoning shows that a resonator, placed in the field of the interfering waves, is submitted to the action of oscillating forces whose amplitude varies periodically with the distance from the mirror. In the mathematical expression for the amplitude of the oscillations set up in the resonator two wave lengths will appear, the first corresponding with the waves emitted by the exciter, and the second with the waves, which correspond with the oscillations to which the resonator naturally gives rise. If the values just given for the logarithmic decrement are approximately correct, the first set of maxima

* *Comptes Rendus*, June 22 1891.

Digitized by Google

and minima positions will be completely masked by the second after about a dozen oscillations have passed away. If the spark in the resonator does not take place until this effect occurs, the nodes and internodes detected by the resonator will correspond with the second system, and not with the first, and it is thus possible to account for the phenomena known by the name of multiple resonance,* without the necessity of the hypothesis by means of which MM. Sarasin and De La Rive have explained their results.

M. Bjerkness acknowledges that the explanation here given was originally given by M. Poincaré, who arrived at it on purely theoretical grounds.

THE GODFROY APPARATUS FOR INCREASING THE EFFICIENCY OF SUBTERRANEAN TELEGRAPH LINES.

The extensive development in France and Germany of subterranean telegraph lines resulted in a demand for a device to render such lines as efficient as those carried overhead. In both countries much the same solution of the difficulty has been arrived at, viz., the employment, as in the case of the long

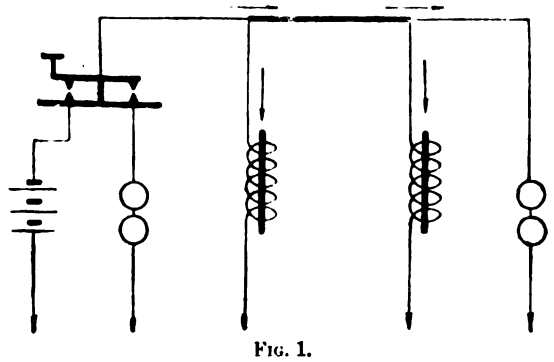

Fig. 1.

aerial lines in India, of "derivations" to earth having considerable inductance. Costly and complicated apparatus are manifestly out of place in land line telegraphy, so that modifications of the devices actually employed on, or proposed for, submarine cables were not attempted, the object being to devise something cheap and simple which could be applied without difficulty to the existing instruments. The particular arrangement favoured by the German Post Office authorities was briefly described in *The Electrician*, Vol. XXVI., p. 241; and it was stated, on the authority of Herr Grawinkel, that by means of this device it had been found possible to transmit Morse signals along subterranean wires at the same rate as on aerial lines up to distances of more than 375 miles, and that on longer lines an increase of speed of 30 per cent. was obtainable as compared with the old arrangement of fixing relays at every hundred miles or so.

In France the arrangement which has met with considerable favour is that due to M. Godfroy, which was first tested at the end of 1888. The diagram, Fig. 1 (from an article by M. H. Cailleret, in the last number of the *Annales Télégraphiques*), shows an underground circuit arranged according to M. Godfroy's simple plan. When the transmitting key is depressed the electromagnetic shunt offers a considerable impedance, and the line is quickly charged. When the key is released, and during the instant when it is neither touching the front nor the back stop, the discharge current (now aided by the E.M.F. of self-induction) goes quickly to earth through the shunt. Similar effects occur at the receiving end, and the net result is sharp, well-defined Morse signalling. In 1888 the Paris-Angoulême line, 310 miles long, having a resistance of 5,000 ohms, and a capacity of 100 microfarads, was fitted with M. Godfroy's device. An ordinary Morse instrument without either local or intermediate relays, attained a speed of 20 words a minute. The shunt circuit, which comprised an electro-magnet with a closed magnetic circuit and a small auxiliary coil, had a resistance of 780 ohms and a coefficient of self-induction of 12 henrys. The battery consisted of 50 Callaud cells. The 1888 experiments showed that, in practice, it was not absolutely necessary to ensure a perfect balancing of the inverse effects of the capacity of the line and the inductance of the shunt. Thus one electro-magnet gave equally good results on lines of from 150 to 200 miles in length, and another could be used on lines varying in length from 250 to 450 miles. It was only necessary to employ a battery suitable to the line, and either to adjust the resistance of the auxiliary coil or to break the magnetic circuit of the electromagnet more or less thoroughly by altering the positions of the soft iron armatures.

Besides the French and German experiments some were carried out on an artificial line by Dr. Tobler at the Zürich Polytechnic. A syphon recorder was placed side by side with the receiver at the transmitting end, and registered the discharge currents from the line curves I*b* and II*b*, and curves I*a* and II*a* (Fig. 2) respectively give an idea of the discharge currents at the transmitting end with and without the Godfroy electromagnetic shunt. The effect at the receiving end is shown in curves IX*a* and IX*b*. Curve IX*a* shows the signals received when the receiver was shunted by a resistance of 700 ohms. On replacing this inert resistance by one having considerable inductance, the curve IX*b* was obtained.

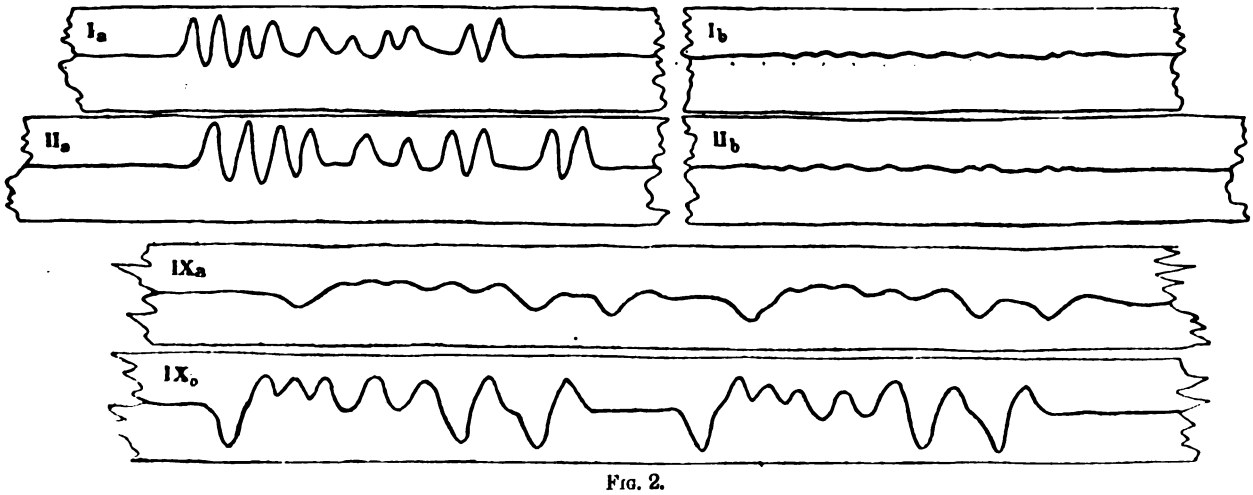

Fig. 2.

In France some 20 long subterranean circuits, such as the Paris-Lyons (300 miles), Paris-Marseilles (650 miles) lines, have had Godfroy apparatus in regular work for the past 12 months and more; and recently it was decided to apply the device to 50 additional lines of over 125 miles in length. The apparatus is made in three sizes, having resistances of respectively 500, 750, and 1,000 ohms, and coefficients of self induction of from 10 to 120 henrys. The apparatus being so simple is cheap, and does not cost more than 15 or 16 shillings.

ELECTROLYSIS BY MEANS OF THE ALTERNATING CURRENT.

BY DR. GUGLIELMO MENGARINI.

The fundamental laws which regulate electrolysis by means of the alternating current are as follows :—

1. The quantity of electrolyte decomposed by the alternating current is always less than that decomposed by a direct current of equal strength, and depends upon the current density at each of the electrodes ; the greater the density the greater being the quantity of the electrolyte decomposed.

2. There exists a limiting current density below which electrolytic decomposition does not take place. This density varies for different electrolytes and electrodes of different materials.

3. The amount of the electrolyte decomposed decreases as the rapidity of the alternations increases.

4. A limiting value to the rapidity of alternation exists, beyond which decomposition does not take place.

In order to establish the truth of these laws, it is not necessary to formulate any special hypotheses ; it is sufficient to consider the phenomena which must be produced by an alternating current in a conductor capable of polarisation.

Suppose we have a circuit traversed by an alternating current which follows an harmonic law ; let i be the current at any time t, and I the maximum intensity ; then

$$i = \mathrm{I} \sin \pi t/\mathrm{T} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

where T is the interval contained between consecutive instants at which the current value is zero. A voltameter is inserted in the circuit, so arranged that both its resistance and that of the circuit can be varied at will, so that whilst the current is maintained constant the pressure between the poles of the voltameter can be varied as desired. To begin with, a very large resistance is inserted in the external circuit, so that the influence of the voltameter on the total circuit is small, and the difference of potential at its poles can be made to approach that occurring with an equal inductionless resistance. The value of this difference of potential at any time will be approximately represented by the expression $e = \mathrm{I\,R} \sin \pi t/\mathrm{T}$, R being the resistance of the voltameter. Suppose that, with the units adopted, R is numerically less than unity, then the maximum ordinates of the new sinoidal curve will be less than those given by (1). We thus get the two curves O A T, O B T (Fig. 1) corresponding in phase, the former representing the change in current, the latter that of the potential difference at the voltameter poles.

Whether we admit that electrolytic decomposition can take place with any electromotive force, or say that separation cannot occur when this force falls below a certain value, it is certain that we must consider polarisation at any instant as an electromotive force opposite in sign to e, and commencing either with or after the intensity phase.

But if in the following reasoning it is desired to assume that electrolytic separation cannot take place below a certain electromotive force, no alteration will have to be made. The same arguments will hold good, the only difference being, as is readily seen, that a deformed instead of a sinoidal curve must be taken to represent the polarisation. It is known that polarisation takes place in voltameters traversed by currents of very short duration (*), in the discharge of condensers (†), and with currents so small that no bubbles of gas make their appearance on the electrodes (‡). For currents lasting only a short time, the polarisation increases in proportion to the current and the time (§), so that the electromotive force due to polarisation can be represented by the expression

$$-\mathrm{P} \int i\,dt,$$

where P represents the electromotive force generated by the passage of unit quantity of electricity through a voltameter such as that considered, of which the electrodes contain unit area.(||)

If p, then, is the polarisation at any instant, we get by performing the integration

$$p = -2\mathrm{P\,I}\,\frac{\mathrm{T}}{\pi} \sin^2 \frac{\pi t}{2\mathrm{T}} \quad . \quad . \quad . \quad . \quad . \quad (2),$$

which shows that the polarisation is represented by a curve of double the period, indicated on Fig. 1 by O P 2 T. The same thing is repeated during the second period of the alternating current. Starting from any instant we can thus obtain the polarisation curve relative to that instant. It is clear, however, that after a very short time there must be a regular position for the curve, and this will accordingly be P P' P''.

In order now to obtain the curve for the difference of potential at the voltameter terminals, we have only to combine the two curves O B T B' 2 O, and P P' P'', whence we obtain the sinoidal

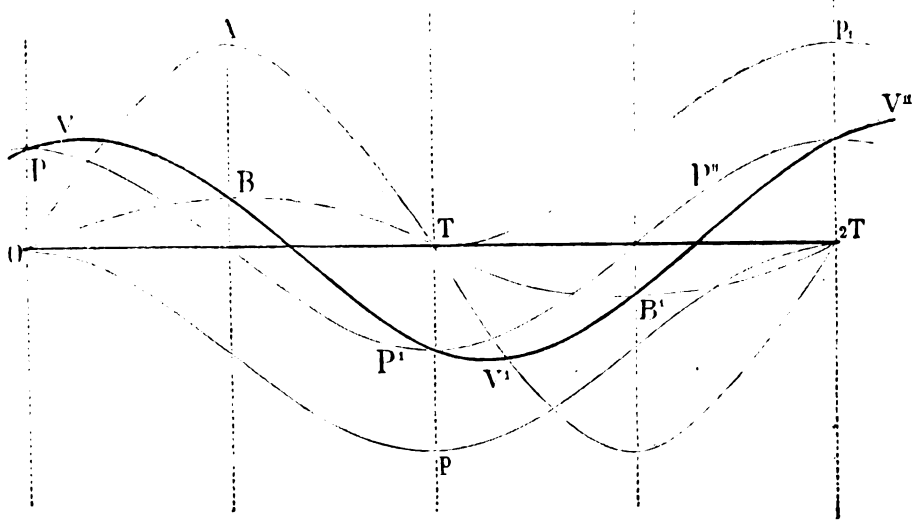

Fig. 1.

curve V V' V'', having a period equal to that of the two from which it was formed.

We see, then, that polarisation, like induction, produces a retardation of phase ; the curves for the current i and the potential difference r at the poles of a voltameter traversed by an alternating current can be represented by the equations

$$i = \mathrm{I} \sin \frac{\pi t}{\mathrm{T}}, \quad r = \frac{\mathrm{I\,R}}{\cos \alpha} \sin \left(\frac{\pi t}{\mathrm{T}} + \alpha \right),$$

where

$$\alpha = \tan^{-1} \frac{\mathrm{P\,T}}{\pi \mathrm{R}}.$$

The expression found for r shows that the phase of the difference of potential at the poles of a voltameter traversed by an alternating current is moved forward with regard to that of the current strength, just as in the effect produced by induction, so that we may say that the insertion of a voltameter in an alternating current circuit is equivalent to putting in a conductor possessing induction.

It should be observed that although we have hitherto spoken of polarisation without decomposition of the ions, still we have implicitly admitted the fact that polarisation increases in proportion to the polarising current. As this is not the case, the curves P P' P'' and V V' V'' will not be really sinoidal, at all events, as regards the longer ordinates, but, nevertheless, the reasoning given holds good. For any electrodes and electrolytes there exists a limit at which the products of decomposition commence to appear.

If we consider the case of the electrolysis of water as effected by two platinum electrodes exactly equal, and placed under the same

conditions with regard to the flow of force between them and all other influences, and further grant, for the sake of simplicity, that the polarisations due to hydrogen and oxygen are equal (although it is not quite certain that they are so, the values found for them by different observers exhibiting slight differences), we can then denote by the two lines C D, E F (Fig. 2), which are parallel to and equidistant from the axis of abscissæ, the limits which must be reached by the polarisation of any given element before the giving off of gas commences.

If the current density at the electrodes is such that the polarisation reaches and exceeds this limit, the polarisation curve can no longer present the sinoidal shape shown in P P′ P″ (Fig. 1), since

Influence of the Current Density at the Electrodes.

Increasing the current density at the electrodes increases the polarisation, so that the limit of polarisation necessary to produce electrolytic separation is reached in a shorter time. This is equivalent, as is shown diagrammatically in Fig. 2, to giving a lower value to the ordinate of the straight lines C D, E F. If, for instance, this ordinate is reduced to half its value, we thus obtain the two lines C′ D′, E′ F′; O C′ and O E′, being half of O C and O E. If we suppose that to increase the current density at the electrodes their area is diminished, whilst the current strength and the rapidity of alternation remain unaltered, the maximum ordinate P I T/π of the curve representing the polarisation

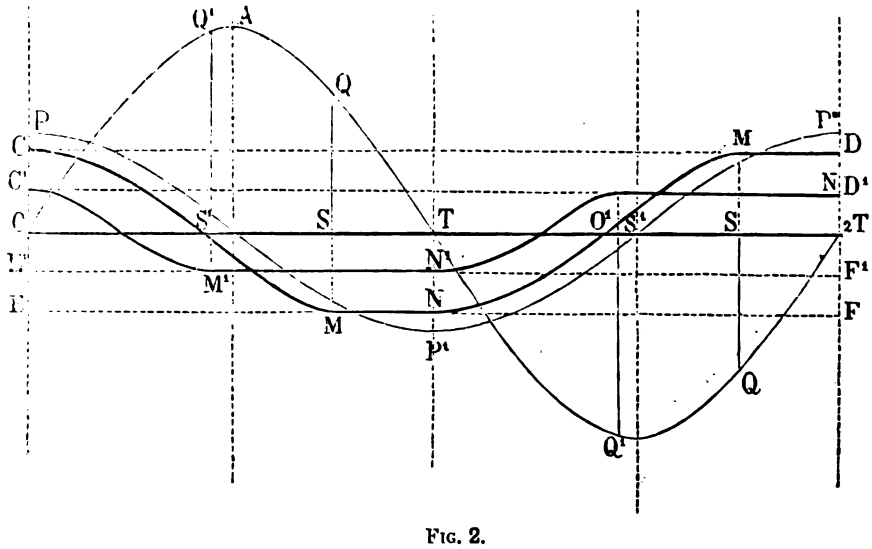

Fig. 2.

no ordinates greater than O C and O E (*see* Fig. 2) can exist. From the instant at which the polarisation attains at the point M the value O E, the liberation of gas will commence and will continue until the end of this period at N. In the interval between M and N the polarisation cannot increase, and its course is, therefore, represented by a straight line parallel to the axis of abscissæ and at a distance O E from it. From this point the polarisation diminishes according to a sine curve until it reaches the value zero at O′. Changing sign here it again reaches at M the limiting value O C, when the liberation of gas recommences, ceasing again at N, *i.e.*, at the time 2 T.

inside the voltameter, will still have its original value, so that whilst the polarisation curve P P′ P″ will still be identical with that already found, none of its ordinates will be able to exceed O C′, so that the liberation of gas will commence at M′ and cease again at N′, and the amount of the electrolyte decomposed at each alternation will be proportional to the area Q′ S′ T, which is not only larger but is more than twice as great as the area Q S T.

The same result will obtain if we suppose the area of the electrode to remain constant whilst the current traversing the voltameter is made to vary. The maximum ordinate of the curve representing the course of polarisation will increase with the

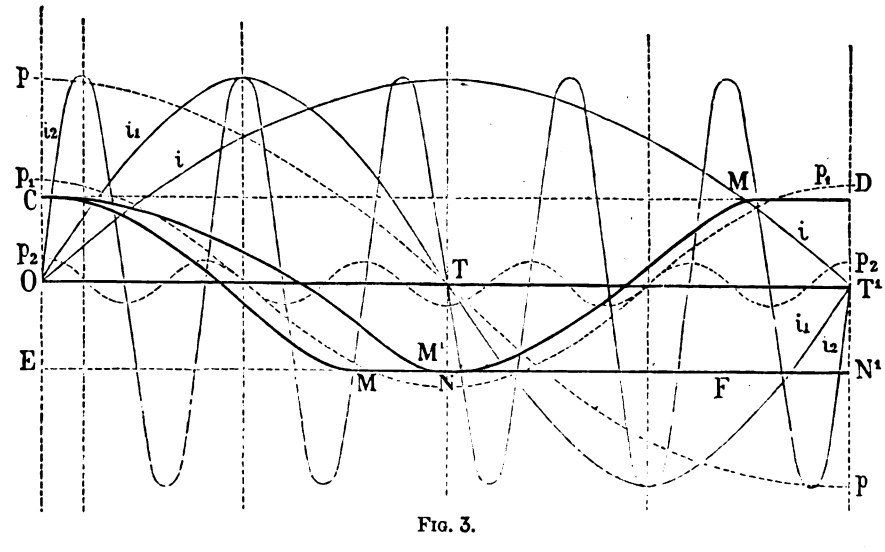

Fig. 3.

Thus during each alternation there is a fraction of the time in which electrolysis proceeds regularly, just as with a direct current, whilst during the remainder it does not take place at all. The quantity of the electrolyte decomposed at each alternation will be proportional to the area Q S T; comparing this with the total area of the curve O A T, which represents the quantity of electricity passing through the voltameter in the time T, we see that the amount of the electrolyte decomposed by an alternating current must be less, except in the limiting case when the line C D coincides with the axis of abscissæ, than that obtained with a direct current of equal quantity.

current, and the quantity of the electrolyte decomposed will increase still more rapidly in relation to the current density than it was found to do in the case considered above.

Therefore in general the quantity of an electrolyte decomposed by an alternating current when the current varies, the surface of the electrode remaining constant, is not proportional to the current passing through the voltameter.

If the current varies as a sine, and remains constant whilst its density at the electrode is made to vary, the quantity of the electrolyte decomposed at various current densities will be represented by the area enclosed by that portion of the curve contained

Digitized by Google

between the respective moments t_0, at which electrolysis commences, and the time T, and the quantity of the electrolyte decomposed is to that decomposed by a continuous current, which causes the same quantity of electricity to pass through the voltameter, as the area enclosed by that portion of the sine curve included between the times t_0 and T is to the total area contained by the portion representing a whole alternation, that is, as

$$\text{Cos}\frac{\pi t_0}{2T} : 1.$$

If the ordinate of the lines C D, E F has the value O P (Fig. 2), electrolytic decomposition can evidently not take place, so that there exists a limiting current density below which decomposition must cease, the voltameter only becoming heated by the passage of the current like an ordinary metallic conductor.

Although there is a certain total polarisation in the voltameter, the current density at each of the two electrodes must be considered separately. The ordinate of the lines C D and E F (Fig. 2) may be different for the two electrodes, since they may be under different conditions; so that whilst one decomposes a sensible quantity of the electrolyte, the other does not. If for the special form of the electrodes, or of the voltameter, the current density is not uniform, the ions will appear only at those portions of the electrodes where the current density is greatest. This will serve to explain the anomalies found by Ayrton and Perry in examining with a Hoffman voltameter the decomposition of water by means of an alternating current.*

From the above it is clear that it is much easier to effect by means of an alternating current of sufficient density the decomposition of water, or any electrolyte giving gaseous ions, than that of one of which one of the ions is solid. And it is on account of this greater difficulty in the case of salts that many persons even now maintain that electrolytic decomposition of saline solutions with the alternating current is impossible.

Influence of the number of alternations.

If at a certain current density an alternating current effects decomposition, it is found that, on increasing the number of alternatings, the separation ceases, but commences again when the number is reduced. For every current density there is a limiting number of alternations, above which electrolysis cannot take place.

Let us denote by K the ordinate O C = O E common to the two straight lines C D, E F (Fig. 2), and by t_0, the time occupied from O to S during which electrolysis does not take place. We observe that in the sine curve C M to the abscissa t_0 corresponds the ordinate O E = − K, and for the curve O p 2 T (Fig. 1) to the same abscissa corresponds the ordinate − 2 K; thus from (2) we get

$$t_0 = T\frac{2}{\pi}\sin^{-1}\left(\sqrt{\frac{K\pi}{PIT}}\right), \quad \ldots\ldots \quad (3)$$

and, therefore, the ratio between the area contained between the times t_0 and T, and that between O and T is given by the expression $1 - K\pi/P\,I\,T$. This shows that in a given voltameter with constant current density the ratio between the quantity of electrolyte decomposed by an alternating current, and that by an equivalent continuous current diminishes as the duration of an alternation diminishes, that is, as the rapidity of alternation increases, and that there must be a limiting rapidity beyond which electrolysis cannot take place. This limit is reached when the curve C M is tangent to the line E F, its maxima ordinate being equal to K, or, in other words, when $t_0 = T$, which occurs when $T = K\pi/P\,I$.

The limiting number of alternations above which all decomposition will cease varies, therefore, in a given voltameter, with K/P and inversely with I, *i.e.*, with the polarisation of the voltameter and inversely with the current; and thus by increasing the current density at the electrodes, the effect produced by an increase in the rapidity of alternation can be counteracted.

Referring to the geometrical diagram already given to show the influence of variation in current density, we will examine the effect of variation in rapidity in the same way.

The three sine curves i, i_1 i_2 (Fig. 3) correspond to the minimum, mean and maximum number of alternations which can be obtained from ordinary alternators, say from 50 to 500 per second; the abscissa O T' representing $\frac{1}{50}$ second. The equations to the three curves may be taken as

$$i = \sin\frac{\pi t}{20{,}000}, \quad i_1 = \sin\frac{\pi t}{10{,}000}, \quad i_2 = \sin\frac{\pi t}{2{,}000},$$

time being expressed in millionths of a second and the maximum current passing through the voltameter being unity.

In order to draw the polarisation curve resulting from equation (2) it is necessary to find the value of the constant P. If we admit with Kohlrausch that a current of unit value in electro-magnetic units passing by way of platinum electrodes 1 square millimetre in area for ·000000124 seconds will produce a polarisation 1 Siemens × 1 Weber,† it follows that a current of 1 ampere decomposing water by means of platinum electrodes of one square centimetre area will give rise to a polarisation of ·0763 volt in 10^{-6} seconds. Thus expressing time in millionths of a second, the maximum ordinates of the three curves representing the polarisation and corresponding to equation (4) will be approximately 1,000, 500, and 100, giving us the three curves p p_1 and p_2 (Fig. 3), in which the ordinates of the polarisation curves are shown to a scale 500 times less than that used for the current curves. As may be seen from the figure the ordinates of the polarisation curve increase very rapidly with the length of an alternation or inversely with the rapidity. If C D, E F represent the limits which may be reached by polarisation in the voltameter without decomposition taking place, we see that p_1 and p reach this limit, whilst p_2 does not, so that when T = 10,000 millionths of a second separation appears from M to N; when T = 20,000 it occurs from M' to N'.

From this figure, then, it clearly appears that with an increase in rapidity of alternation the quantity of the electrolyte decomposed decreases, and that for every current density there exists a limiting value for the rapidity of alternations, beyond which decomposition does not take place.

(To be continued.)

CONTRIBUTIONS TO THE STUDY OF THE SPECIFIC INDUCTIVE CAPACITY OF LIQUIDS.*

BY A. PEROT.

Silow proposed the following method for measuring the specific inductive capacity of liquids. A quadrant electrometer, used idiostatically, is successively immersed in the two fluids to be compared. If C_1 and C_2 are the couples acting on the needle, in the two cases, for the same deflecting potential applied to the quadrants, the ratio of the specific inductive capacities of the two substances is

$$\frac{K_1}{K_2} = \frac{C_1}{C_2};$$

or, if the second medium is a vacuum, or air, for which the value of K may be assumed to be equal to unity, the value of K for the first body is simply C_1/C_2.

Thus the value of K is obtained by two successive experiments in which the positions of equilibrium of the needle are observed. It necessarily follows that if K varies with the duration of charge, it is not possible to observe any changes in its value till the oscillations of the needle have died away, and any initial changes in K are quite masked by these vibrations.

In order to study more precisely the variations in the inductive power of liquids when first subjected to electrification, M. Perot has modified Silow's method in the following manner:—An apparatus was constructed consisting of two electrometers, of which one had air as its dielectric, and had a capacity which can be varied at will, while the second is immersed in the liquid to be studied. The moving parts of the two electrometers are rigidly connected, and are arranged so that the electrical forces in the two instruments are opposed to each other. By adjusting the capacity of the air condenser forming the first instrument, it is possible to adjust the opposing forces to exact equality, so that the movable part of the apparatus experiences no resultant force when it is charged. If the instrument is so adjusted at the end of, say, five minutes after charging, one can, theoretically, at all events, deduce the values of the geometric capacities of the two condensers and the specific inductive capacity K of the body at the end of that time. Now discharge the apparatus, and charge afresh. If no motion of the movable part is observed, the value of K is independent of the time of charging, but otherwise K must be regarded as a variable.

The results obtained show that much depends upon the purity of the liquid, and M. Perot accordingly confined his attention at first to liquids rigorously deprived of water by the prolonged action of sodium. The liquids chiefly used have been benzine, the essence of petroleum, and chloroform.

The first apparatus of M. Perot consisted of a differential weight electrometer. The two attracted plates were placed at the extremities of a lever like the pans of a balance, the electrical attraction on the plates forming the weights to be compared. Under each plate an earth plate was placed. The height of one of these was adjustable, so that the attractions could be balanced; and on the other was placed a trough containing the liquid under test. After adjusting for balance when the movable plates were charged, the instrument was discharged for an instant and charged again. One of the pans was then found to move upwards, to oscillate, and finally to return to its former position of equilibrium. The motions obtained indicated that for pure anhydrous liquids K_0 was less than K, where K_0 is the specific inductive capacity at the instant of

charging, and K the corresponding value at the end of five minutes. For impure liquids K_0 was, however, often greater than K. M. Perot considers that the results obtained must really be attributed to alterations in K, and not to differences in conducting power, because the difference between K and K_0 is sometimes positive and sometimes negative. The electrometer-balance was not much used, as actual measurements of the values of K and K_0 could not easily be made. The instrument was abandoned in favour of a differential quadrant electrometer, illustrated in Fig. 1.

This instrument consists of two Branly electrometers superposed, the two needles having a common axis, and being suspended by a

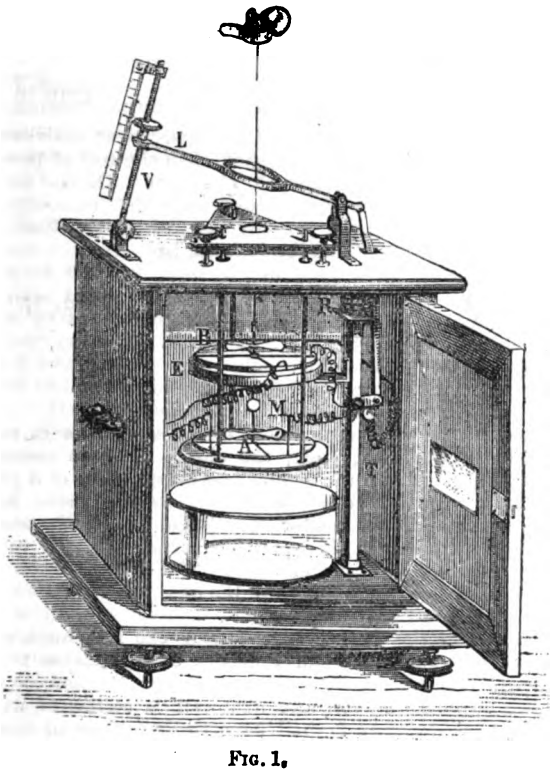

FIG. 1.

platinum wire ·05 of a millimetre in diameter. The sectors of the lower electrometer, A, are attached to a fixed support, but those of the upper electrometer, B, are movable vertically by a mechanism shown in the figure, and their position can be adjusted to about ·01 millimetre. The weight of the double needle, including the mirror M, is about four grammes. The sectors are gilt, and the interior of the case is covered with tinfoil in connection with the

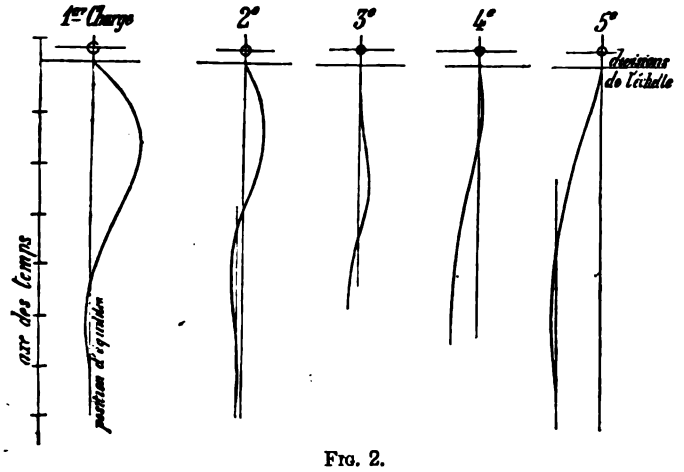

FIG. 2.

earth. The deflection of the needle is observed by Poggendorff's method. The electromotive force used was about 270 volts. The quadrant sectors are so connected that the two couples acting on the needle are opposed to each other. The following is the process used in obtaining the specific inductive capacity :—The needle is connected with a pair of sectors of each electrometer, and the upper instrument B is adjusted till the deflection is zero, when the potential is applied. Let p_1 be the reading of B for this position. Now raise the glass vessel containing the liquid till the lower electrometer is immersed, and take the new reading p_2 of B. It has been shown that the electrometer deflection remains at zero if the liquid is perfectly pure, whatever the time of charge, and that p_2 is independent of the value and the sign of the potential acting on the quadrants. In order to determine K it is now necessary to find the relative values of the two couples acting on the lower needle when the readings of B were p_1 and p_2 respectively. To do this the sectors of A are all connected to earth, while a cell of suitable voltage is applied to B when the readings are p_1 and p_2, and the respective angular deviations d_1 and d_2 are observed. Then, taking the inductive power of air as I, we have

$$K = \frac{d_2}{d_1}.$$

The following values were obtained for benzine and essence of petroleum. The square of the refractive index for the ray D of the spectrum is also added for comparison.

	K		n^2
Benzine	2·235	.....	2·25
Essence of petroleum ...	2·170	.....	2·11

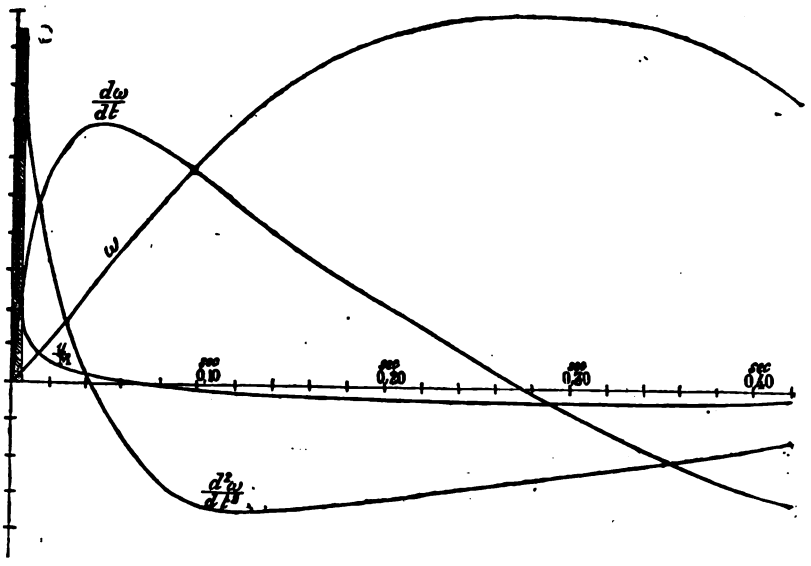

FIG 3.

In order to find the value of K_0 the instrument was adjusted five minutes after charging, was then discharged, and immediately charged again. The mirror is then observed to receive an impulse in one direction, say to the right, and returns to zero after a few oscillations. If the sectors of the air electrometer are slightly lowered the initial impulse to the right is diminished, and the final position of equilibrium is a little to the left of zero. If the sectors are still further lowered, the impulse to the right is continuously

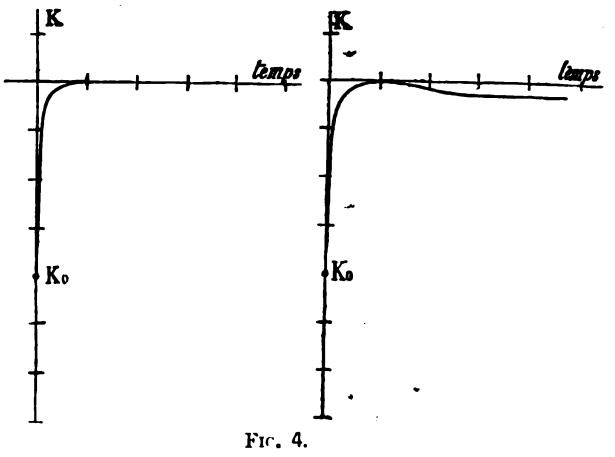

FIG. 4.

diminished. The time curves of the deflection for five successive adjustments of the electrometer B are shown in Fig. 2, and were obtained by direct photography of the movement of the needle. If we estimate the specific inductive capacity from the reading of the electrometer B (such as the 5th in Fig. 2), which corresponds to no initial impulse of the needle, we obtain a value K'_0, which is a superior limit of the value of K_0. The effect of an impulse imparted to a movable system is more and more apparent as the moment of inertia of the system is diminished, and an impulse which would not be perceptible with one needle would be rendered apparent by sub-

Digitized by Google

stituting a lighter needle for it. The values found for K'_0 in the experiments on benzine varied from 1·65 to 1·68 for one needle, but for a very light needle it was only 1·10. This value 1·10 is the smallest value actually found, but M. Perot considers that the true value of K_0 is really unity.

The next question which M. Perot discusses is the manner in which K_0 changes until it reaches the final value K. The differential equation of the motion of the needle is of the form

$$M\frac{d^2\omega}{dt^2}+m\omega+f\left(\frac{d\omega}{dt}\right)=\mu$$

where M is the moment of inertia of the needle, m the torsional couple of the suspending wire per unit angle, $f\left(\frac{d\omega}{dt}\right)$ the couple due to the damping forces, and μ the moment due to the electrical forces. ω is the angular deflection of the needle at the instant t. The value of μ can be found from this equation if the coefficients are known, since the values of ω, $\frac{d\omega}{dt}$ and $\frac{d^2\omega}{dt^2}$ can be determined graphically from the photographed curves shown in Fig. 2. M. Perot found, by studying the vibrations of the needle when left to oscillate freely, so that no electrical forces were acting, and $\mu=0$, that the motion of the needle could be represented by the equation

$$\frac{d^2\omega}{dt^2}+0{\cdot}01834\,\omega+0{\cdot}2314\frac{d\omega}{dt}=0,$$

and hence the electrical couple at any moment may be obtained from the equation

$$\frac{\mu}{M}=\frac{d^2\omega}{dt^2}+0{\cdot}1834\,\omega+0{\cdot}2314\,\frac{d\omega}{dt}.$$

By the careful application of graphical processes to the photographic curves indicated in Fig. 2, M. Perot was able to deduce the curves connecting ω, $\frac{d\omega}{dt}$ and $\frac{d^2\omega}{dt^2}$ with the time, and thence, by application of the above equation, to find a similar curve for μ/M. The resulting curves are shown in Fig. 3. The value of K at any moment can be readily deduced from the corresponding value of μ/M. The moments of the couples acting on the needles are $C_1 V^2$ and $C_2 K V^2$, where C_1 and C_2 are constants, K is the specific inductive capacity of the liquid, and V is the potential applied to the quadrants. The difference between these moments is μ, the resultant electrical couple. Thus

$$(C_1-C^2K)V^2=\mu,$$

or,

$$K=\frac{C_1}{C_2}-\frac{\mu}{C_2V^2}=\frac{C_1}{C_2}-\frac{M}{C_2V^2}\frac{\mu}{M},$$

so that the variations of K follow those of μ. The curve representing K as a function of the time for the liquid (essence of petroleum) on which the observations were made, is like the second curve of Fig. 4, which is very similar to the first curve of the same figure.

The conclusions at which M. Perot arrives may be summarised as follows :—

1. The specific inductive capacity, after the charging potential has been applied for one second or more, depends neither on the time of charging, nor on the potential applied, nor on the previous history of the liquid. The value of K is equal to the square of the index of refraction, as required by Maxwell's theory.

2. The initial value of the specific inductive capacity is very nearly unity.

3. The rate at which the specific inductive capacity changes from its initial value, K_0, to its final value, K, is extremely rapid.

THE ELECTRIC TRANSMISSION OF POWER.*

BY GISBERT KAPP.

(Continued from page 279.)

Now let us see how such a system of transmission will have to be worked, and what the working expenses will be. I take, by way of example, five miles as the distance between the generating station, which may be the tramway depôt or a central electric light station on the line of tramway, and the delivery station. At either terminus we must have mechanical appliances for loading and unloading the batteries from the car, such as are generally used in connection with storage cars. Early in the morning a charged battery is put on the car, and run out to the delivery station, where it is unloaded and connected to the motor. The other battery, which has served during the previous day, is loaded on the car and taken back to the depôt to be charged up again. In this manner the car need only make one journey out and one journey home daily. As its speed may be very moderate, say from three to four miles an hour, the cost of running this car will be much less than that of a passenger car, which must stop and start every few minutes, and run at a higher rpeed. I take 3d. per car mile as the cost of haulage, including the use of plant, and I further allow 2s. a day for labour in loading and unloading the batteries. The account of working expenses will now stand somewhat as follows :—

	£	s.	d.
Power at generating station at £10, allowing 65 per cent. total efficiency*	77	0	0
Haulage	37	10	0
Labour	30	0	0
15 per cent. interest and depreciation on batteries (£340)	51	0	0
10 per cent. interest and depreciation on electric machinery (£150)	15	0	0
Total annual cost	£210	10	0

This works out at £42. 2s. per annum per horse-power delivered, and is therefore quite as high, if not higher, than the cost of power obtained by a small and uneconomical local engine. On the score of economy there is consequently no advantage in transmitting power by storage batteries in the present case, where the distance of transmission is five miles. Had the distance been less, the working expenses would also have come out smaller, but not by any considerable amount. The only item in which we could save is cost of haulage, and if we neglect this altogether we have still to pay £34. 12s. per annual H.P. delivered. Battery transmission can therefore not compete against power produced by a local engine, even if the latter be of the rather uneconomical type which users of small power still tolerate. But how stands the case if for some local reason the employment of a heat-engine of any kind is precluded? We have, then, the choice between electric transmission by means of batteries, and directly by means of a pair of wires. Which will be the more economical? As the dynamo and motor, except, perhaps, in the matter of voltage, will be the same in either case, the answer to this question turns upon the comparison of the batteries and line of wires. The first question to consider is whether our wires may, in the case of direct transmission, be carried overhead on poles and insulators, or must be put underground. If the former be the case, the line need not cost more than £130 per mile ; and I may at once mention that, from the experience gained with various power transmissions, which I hope to bring before you, this item can be estimated with a fair degree of accuracy. As I shall have to deal more in detail with the cost and construction of live power transmission plants later on, I shall not enter into details at present, and must ask you to take my statements as to cost of line and cost of power transmitted as correct, though I do not now show how the account is made up. As regards transmission by wires placed underground, there is, as far as I know, no example of such an installation, and we can, therefore, not verify our estimate by reference to work actually executed, as we can in the case of overhead transmission. We are thus forced to calculate the cost of the line according to the data obtainable for electric light mains, and I take for this purpose an estimate made by Mr. Crompton in his Paper on "Central Station Lighting," read before the Institution of Electrical Engineers, on the 12th of April, 1888. In this Paper Mr. Crompton gave tables for the cost of underground mains of various types and sizes, and by reference to his tables I find that a main of the section required for the transmission of 5 H.P., and insulated so as to safely bear a pressure of 1,000 volts, would cost about £670 per mile. We have now all the necessary particulars for making a comparison of the cost of battery transmission and direct transmission, the latter by both overhead and underground wires. The following table gives the result. The cost includes the charge for power at the generating station (taken at £10 per annual H.P.), and interest and depreciation on the plant, which is taken at 15 per cent. for the batteries, and 10 per cent. for the line and electrical machinery.

Transmission plant for 5 H.P.

Distance of transmission in miles.	Annual cost per H.P. delivered, if the transmission is		
	By batteries.	Direct.	
		Overhead.	Underground.
1	£36·1	£22·8	£33·6
2	39·1	25·6	47·2
3	37·9	28	60
4	40·6	30·6	74
5	42·1	33	87

* Cantor Lecture delivered before the Society of Arts, February, 1891.

* In this case, the efficiency is the ratio of the power supplied to the charging dynamo to that obtained from the motor, and does not include power spent in transmission being charged for in the account at 3d. per car-mile.

Digitized by Google

We see from this Table that if there is no objection to an overhead line, the electric transmission of stored power by means of batteries cannot compete against the direct transmission of live power by means of a pair of wires, even if the distance is considerable. But in towns we cannot have, or at least we ought not to tolerate, overhead lines, and if we work with an underground line we find that, for distances exceeding one mile, the battery is a more economical transmitting agent than the wire. Here we have at last found a case where it will be advantageous to transmit power by means of storage batteries, but there are so many conditions attached to the case that the field of application of such a system must necessarily remain very limited. First, the power must be required, so to say, in small parcels; secondly, there must be a tram line handy, and the customer must have facilities for loading and unloading the batteries and accommodating them on his premises; thirdly, there must be a charging station on the line having similar facilities; fourthly, the use of an overhead line must be excluded; fifthly, the distance must exceed one mile; and, finally, there must be some reason why a local engine cannot be used. I need hardly point out that a system of transmission fenced in by so many conditions cannot have any commercial importance. Thus far, the result of our investigation is entirely negative. We find that transmission of power by means of storage batteries, whether the power transmitted be large or small, is not so economical as other methods of transmission, and has, therefore, no commercial value for all cases where these other methods are applicable. If I have, nevertheless, devoted some part of this lecture to the subject of battery transmission, it was because the idea of distributing power, so to speak, bottled up in batteries, seems to have a fatal charm for many inventors. It is an old idea, but is always coming up again, and for this reason I thought it advisable to go a little into figures and show you how the case really stands. It might perhaps be objected that as no distribution of stored power by means of ambulant batteries has as yet been practically introduced, it is premature to give an opinion as to the possibilities of such a system. The idea of battery distribution of power is, as a matter of fact, entertained not only by amateur electricians, but also by practical engineers. As an example of this fact, I may quote a passage in a report written about two years ago by Mr. J. F. Fanning. This gentleman, reporting to the Cataract Construction Company on the question of utilising the power of Niagara Falls, says:—"Power and lighting currents may be electrically transmitted to neighbouring cities, and possibly storage batteries may be electrically charged and re-charged, and many times forwarded for use in surrounding cities." When writing this, Mr. Fanning had, of course, in view cheap water-power, and probably canal transportation. If, at the same time, batteries could be made cheaper, lighter, and more durable than they actually are at present, then, but not until then, will they become commercially possible as transmitting agents in competition with other systems of power transmission. Taking batteries as we find them at present, their use as agents in the transmission of power is only justifiable in cases where the direct transmission by means of conductors cannot be employed; and this brings me to the consideration of the only case of the electric transmission of stored power which as yet has attained to practical importance—namely, the use of batteries for locomotive purposes.

Although electric tram-cars come strictly, speaking, within the title of my lectures, I do not propose to consider them at any length, the reason being that this branch of power transmission alone, if treated in detail, would absorb all the time at my disposal. I shall, therefore, content myself in taking up the subject only so so far as is necessary to show in a general way what is the present practice in this branch of power transmission.

We have in this country two very good examples of battery tram-cars, the one being the cars now running in Birmingham, and the other the cars on the Barking-road line in the North of London. Of the former I have not been able to obtain much information, but of the latter I have by the kindness of Mr. Thomas Fraser, who superintended the erection and working of the plant, been able to obtain all the information required for my purpose. I am also indebted to Mr. Reckenzaun for information regarding his cars, which are in use at Philadelphia. The following table gives the principal data of these cars, conveniently arranged for comparison and reference.

Taking the averages of the last two lines in the table, we find that for a car representing a total rolling weight of 10 tons, we require a battery capable of giving a maximum output at its terminals of 19 E.H.P., and a mean output of 5·6 E.H.P. It must, however, be noted that the latter figure applies to the time the car is actually in motion, and does not include the power wasted in starting. Mr. Fraser has made very careful observations of the power flowing out of the batteries during the whole of the time the car is in service, and found that the integrated power divided by time came to 7·33 E.H.P.; that is to say, a motor taking from the batteries all day long 7·33 E.H.P. will take from the batteries the same amount of power that is actually taken under the intermittent work going on in the running of a tram-car. Of the 7·33 E.H.P., a good motor will yield about 6½ B.H.P. Taking the efficiency of the batteries at 60 per cent., a figure by no means too low when we consider the very irregular nature of the work done by these batteries when in service, we find that the E.H.P. of the charging dynamos required per car is about 12 E.H.P. The ratio between the indicated power of the engine and the output of the charging dynamo may be taken at 80 per cent., so that we shall have to provide engine-power at the rate of 15 I.H.P. for every car, provided the engines are worked for the same number of hours that the cars are in service. If the engines are worked for a longer time, say by night as well as by day, a corresponding reduction in the total indicated power of the station can, of course, be made.

Storage-Battery Tram-Cars.

—	Birmingham.	Barking-road.	Philadelphia.	
			Small car.	Large car.
Weight of car (in tons)	—	3·275	2·500	3·620
„ motors gear (in tons)	—	1·360	·980	1·140
„ batteries (in tons)	2·850	2·400	1·770	2·450
„ passengers (in tons)	3·300	3·600	2·230	3·600

Percentage of paying load	31·5	34	30	33·2
Number of cells	96	96	84	116
Maximum current	—	70	70	80
Maximum energy at battery terminals (E.H.P.)	—	19	14	23
Average energy at battery terminals (E.H.P.)	—	6	4·8	5·4
Maximum energy per 10 tons of rolling wght. (E.H.P.)	—	17·8	18·7	21·3
Average energy per 10 tons of rolling wght. (E.H.P.)	—	5·65	6·42	4·95

Returning now to the subject of the cost at which stored power can be retailed by electric transmission to small consumers, let us briefly glance at the rival system, namely, the distribution of small parcels of live power from a central electric light station. One hears it often stated that the supply of power, and not that of light, must become the chief business of such stations. The argument in support of this view is somewhat as follows:—The demand for light is very uneven, being less than a tenth of the capacity of the station for many hours during the day, and rising very rapidly towards evening. The period of large demand comprises only a few hours, and during that time the engines work with great economy. During the remainder of the day the economy is less; and, in fact, the greater portion of the coal bill, cost of attendance, and interest on the capital outlay is chargeable to light running. If, therefore, by the sale of power, we could keep the central station plant economically working during the whole of the day, the increase on the working expenses would be slight, but the increase of revenue would be very considerable. This argument is perfectly sound, but it has the rather serious defect that it will not convince the very people from whom this large increase of revenue is to be obtained; for, let us see what it means to the use of power. As you know, electric current is supplied from central stations, at a charge varying from 4½d. to 8d., and even 1s. per Board of Trade unit. The usual charge in London is about 7d. Now, suppose a small manufacturer, requiring only a few horse-power, determines to discard his small steam or gas engine, and put up an electromotor, to be worked by current from a central station, what will the power cost him? This, of course, depends on the time—that is, the number of hours in the year during which he requires power. If he has a small factory, in which work is steadily going on day by day, you may estimate that the power will be required during 3,000 hours per annum. It is now very easy to calculate the annual cost of each brake horse-power. Allowing £1. 10s. per horse-power for depreciation and interest on the motor, and £1 for petty stores, we fine that, at 7d. per unit, the annual horse-power comes to £75. With current at a different price, the cost of power will be accordingly altered, as shown in the table:—

Power Derived from a Central Station.

Cost of Board of Trade unit	d. 1	d. 2	d. 3	d. 4	d. 5	d. 6	d. 7	d. 8
Cost of annual brake horse-power for 3,000 hours	£ 12·9	£ 23·3	£ 33·5	£ 43·9	£ 54·2	£ 64·5	£ 75	£ 85·4

It is clear, from this table, that the small user of power will only use an electromotor if he can get current at about 3d. per unit, and, unless electric light companies can supply at this price (which at the present time does not seem likely) there is no prospect of supplying electric power to small factories wanting the power continuously. Another disadvantage is that the demand for power

Digitized by Google

must, in winter at any rate, overlap the demand for light, hus requiring the erection of additional plant. If, however, the power is only required intermittently, then the electromotor is by far the cheapest instrument for producing it, not only as regards first cost, but also as regards working expenses. There are many small trades in which power is wanted only for a few hours during the day. If, for instance, the actual running time of a lathe is two hours daily, then the cost of the annual horse-power, with current at 7d. would only be £15, a figure which cannot be touched by either steam or gas. There is the further advantage of having the power always ready. There is no need to get up steam, look to the feed pump, open cylinder cocks, turn the engine over the centre, and generally do the dozen little things which are required in starting an engine. With a motor all that is required is to turn on the switch when the power is wanted, and to turn it off again when the job is done. For domestic purposes again, nothing could be more handy and economical than electric power supplied from a central station. I have here a collection of appliances, for the loan of which I have to thank the Keys Electric Company, and I can show you how easy and convenient it is to apply electric power to small domestic machinery.

I have in the present lecture dealt with what may be termed general questions of engineering policy rather than with technical details, and I am afraid you will have found the financial parts of the lecture rather a dry subject. The question of cost is, however, of the utmost importance in engineering work, and it was, therefore, necessary to give it some consideration. In the remaining two lectures I shall be able to turn to the more interesting parts of our subject, and bring before you some of the scientific principles and technical details relating to the electric transmission of live power over long and short distances.

(To be continued.)

ELECTRIC LIGHTING ORDERS.

In a Parliamentary Return, just issued, the Board of Trade state that 70 applications for Provisional Orders have been made since the issue of the last report; of these 37 were made by local authorities, and 33 by companies, and 12 related to London. The orders granted to companies have, without exception, been granted with the consent of the local authority of the district. In the case of the Order granted to the New Cadogan and Belgrave Electric Supply Company, in respect of a portion of the parish of St. Luke, Chelsea, the local authority consented to the grant of an Order to the Company, but objected to certain provisions which were inserted by the Board of Trade, at the instance of the London County Council, in accordance with their usual practice in the case of Orders relating to the metropolis. A special report with respect to this Order was made to Parliament, who recently decided to delete the clauses objected to by the Chelsea Vestry. The Orders granted this year to a great extent follow the form of the Orders granted last session; but a clause has been inserted forbidding the placing of electric lines above ground without the express consent of the Board of Trade. At the request of the Corporation of Edinburgh, the Board of Trade inserted a provision in the Bill to confirm the Edinburgh Electric Lighting Order, authorising the Corporation, with the consent of the Secretary for Scotland, to borrow money for electric lighting purposes and to keep the accounts of the undertaking authorised by the Order under the provisions of the Edinburgh Municipal and Police Acts, which regulate the other borrowing powers and accounts of the Corporation, instead of under the Electric Lighting Acts.

The following is a complete list of the Provisional Orders granted this year :—

C. = Company. L.A. = Local Authority.

Acton, L.A.	Kingston-upon-Thames, L.A.	Preston, C.
Birmingham, C.	Leeds, C.	Scarborough, L.A.
Bishop's Stortford, C.	Liverpool, C.	Southend, L.A.
Bolton, L.A.	Llanelly, L.A.	Southport, L.A.
Bromley, L.A.	London—	South Shields, L.A.
Canterbury, L.A.	Camberwell, C.	Stockport, L.A.
Cardiff, L.A.	Chelsea, C.	Sunderland, L.A.
Chiswick, L.A.	City of London, C.	Surbiton, L.A.
Coventry, L.A.	Islington, C.	Torquay, L.A.
Croydon, L.A.	North London, C.	Toxteth Park (Liverpool), C.
Dewsbury, L.A.	Southwark, C.	Tunbridge Wells, L.A.
Ealing, L.A.	Wandsworth, C.	Tynemouth, L.A.
Edinburgh, L.A.	Westminster, C.	Weston-super-Mare, L.A.
Exeter, C.	Woolwich, C.	Weybridge, C.
Hanley, L.A.	Londonderry, L.A.	Whitby, L.A.
Harrogate, L.A.	Newcastle, C.	Whitehaven, L.A.
Heckmondwike, L.A.	Newport (Mon.), L.A.	Withington (Manchester), C.
Hertford, L.A.	Norwich, C.	
Ipswich, C. (2)	Paisley, L.A.	
Kidderminster, L.A.	Poole, C.	
Killarney, C.		

In all, 58 of the 70 Orders applied for have been granted, 34 to local authorities, and 24 to companies.

Bills Nos. 1 to 4, confirming these Orders, received Royal Assent on June 11th. Bills Nos. 5, 6, 7, 9, and 11 are awaiting Royal Assent. The other Bills are still before Parliament.

No applications for licences have been received since the date of the last report. But the two licences referred to in the last report were granted. These were to Crompton and Co. (the Borough of Chelmsford), and Mr. H. G. Massingham (Bath).

Since 1883 no less than 218 Provisional Orders have been granted. Of these, 61 have been revoked or repealed, leaving 157 still in force, 94 of which belong to local authorities. During the same period 20 licences have been granted, only 12 of which now remain in force. During the electric lighting mania of 1882-83 69 Orders were granted, only 13 of which (all belonging to local authorities) still exist.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—JULY 14TH.

The Patent Office.

Mr. LENG rose to move the reduction of the item for the Patent Office by the sum of £100. He said he did this in order to advocate the redress of a grievance which was felt to be serious by the large and important class of inventors in this country. The fees were such as might be from time to time, with the sanction of the Treasury, prescribed by the Board of Trade. The initiative in reducing the fees rested with the Board of Trade, so that if there was a strong case for the reduction of these fees, and they were not reduced, the responsibility primarily rested with the President of the Board. The Chancellor of the Exchequer had admitted that the receipts of the Patent Office for the year 1889 were £93,534 in excess of the expenditure. The report for the year 1890, since issued, showed a large increase on that large sum—viz., £109,366. The Patent Office for the year yielded no less than £165,000; designs, £4,500; trade marks fees, £16,400; and the sale of publications, £6,000, making a total of £192,000; while the total expenditure of the Patent Office was only £83,240. The rigth hon. gentleman said that manufacturers did not object to fees which had the effect of extinguishing useless patents, and that it was in contemplation to spend a considerable sum on new buildings. The Chancellor of the Exchequer had been misinformed regarding the views of manufacturers. There had been memorials from manufacturers and inventors in Liverpool, Birmingham, Manchester, Leeds, and London, praying for a reduction of the fees. He had been almost overwhelmed with correspondence from all parts of the kingdom, urging him to persevere with this motion. The cost of a patent in this country was largely in excess of that in any other country in the world. The British Government exacted £154 for a patent for 14 years, against £7. 10s. in the United States for 17 years. Protection for four years cost only £4, but the payment of £100 for the fifth year brought that up to £14, being for five years about double the charge in the United States for 17 years. The Patent Office did nothing to ascertain or to guarantee the validity of a patent. On the other hand, the United States Patent Office for the £7. 10s. it received insured the patentee a real title by a painstaking examination by the best experts. Computing the fees for the number of years for which the patents existed in the different countries, the average charge in each country was as follows :—United States, 8s. 5d. per annum for 17 years; France and Italy, £4 per annum for 15 years: Belgium and Spain, £4. 4s. per annum for 20 years; Russia £5. 10s. per annum for 10 years; Great Britain, £11 per annum for 14 years. This country was far behind even Russia, our fees being 100 per cent. more than those in that benighted land, while they were 2,500 per cent. more than those in the United States. How far fees affected the number of patents was shown by the following returns for 1887, for Great Britain and the United States respectively :—Applications, 18,051—35,613; patents granted, 9,410—20,429; income from fees, £124,279—£228,902; expenditure, £81,577—£198,892; surplus, £42,702—£30,010; patent fund, none—£651,498. It thus appeared while the small fees encouraged the taking out of double the number of patents in the United States, the total amount of the fees was double that in this country, and a very large patent fund had been accumulated. This country, in effect, levied a heavy tax upon its inventors, on the men to whose ingenuity it was so largely indebted for its manufacturing and mercantile prosperity. The United States, on the other hand, made the smallest reasonable charge on the inventor, with the result that almost every American citizen was a patentee. America encouraged her poor newsboys, like Edison, to become distinguished inventors and millionaires, while the Patent Office in this country exacted fees which to many a poor man were prohibitory, and, although in many cases he might scrape together the £4 charged during the first four years, he was quite unable to pay the £10, £15, and £20 per annum exacted during the remaining 10 years. The right hon. gentleman the member for West Birmingham, when President of the Board of Trade in 1883, introduced a great improvement on the system which had previously existed. Under the Patent Act of 1852 the patent fee of £150 was required to be paid in two instalments of £50 and £100 respectively, which covered the patent for 14 years. Under the Act of 1883 the total sum of £154 was spread over 14 years in the following manner :—£1 was charged on filing the provisional patent, and £3 on its completion, so that for the first four years the total charge was only £4. Then from the end of the fourth year till the end of the seventh year £10 per annum had to be paid, for the next two years £15 per annum, and the next four years £20 per annum. These changes led to a large increase in the number of patents. Under the Act of 1852 the largest number of applications was in 1882, the total being 6,241, but immediately after the passing of the Act of 1883, which spread the fees over a number of years, the applications rose to 17,110, and they had gone on steadily increasing, until in 1889 the number was 21,008. The easier method of charging the fees, although the total fees

Digitized by Google

remained the same, had led to an increase in the number of applications for patents of between 300 and 400 per cent. The reason why the renewal fees were left unaltered in their aggregate amount was, that it was feared that without these the administration of the Patent Office might be carried on at a loss, owing to the reduction brought about by the diminished fees. But now that it was plainly evident that there was no risk of such loss as was then feared, owing to the number of patents having increased fourfold through the easier method of paying the fees, the time had come to consider the question of renewal of fees *de novo*. Even if the fees were reduced, and reduced very considerably, there would not be a proportionate reduction of the total receipts of the Patent Office, but we should see that as the spreading of the fees over a number of years led to a large increase of applications, so would the lessening of the annual payments. Many more patents would be applied for, and many more payments made, which would compensate, to a large extent, for the reduction of the fees. No one would object to a reasonable and prudent expenditure in enlarging the Patent Office. The accommodation at present was miserable. The library was a limbo where inventors soon lost themselves and gave up searches in despair. Much might be done to improve the arrangements. A larger staff of compilers of abridgments should be employed, so that they might be brought closely up to date. The American system of examination should be adopted, to prevent duplicating and triplicating patents for the same invention. In some points the Patent Acts should be amended, especially in conformity with the valuable report made some time ago by the Chairman of the Chemical and Allied Trades Committee. With a surplus of £110,000 a year to work upon, the Patent Office might do much to encourage poor inventors by purchasing from them inventions of real utility, and making them free to the public. He did not contend for the total abolition of renewal fees, but he did say that to tax inventors £150 on each invention, in a country which had so much to gain from the encouragement of inventions, was most injurious, not only to the inventor, but to the country. A comparatively small annual payment during the currency of the patent should suffice, and either £3 or £5 per annum would be quite sufficient. The present system of transferring the annual surplus from the Patent Office to the Treasury was very objectionable. When so transferred, the money was lost sight of, and inventors were apt to forget how heavily they were being taxed. During the last five years these surpluses had amounted to fully £360.000. The Patent Office revenue ought to be distinctly ear-marked, and appropriated for the advantage of inventors, and not thrown hotch-potch into the general revenue of the country. It was extremely inconsistent on the part of the Government to grant large sums on the one hand, for technical education, and then, on the other, to tax those who were technically educated, and were turning their technical education to good account. We should not only endeavour to fetch up our leeway, so far as technical education was concerned, but we should adopt all the enlightened methods we could devise to stimulate and encourage inventors in all the arts and crafts which are the foundation of our manufacturing and mercantile preeminence. Instead of our Patent Office being a helpful promoter of inventions, it was a hard, niggardly, unsympathising tax collector, bent on screwing all it could out of the poor inventor, while aiding him as little as possible. In conclusion, he would respectfully urge the President of the Board of Trade, and his colleague, the Chancellor of the Exchequer, no longer to look at this question merely from the manufacturer or capitalist's point of view; no longer to look at it from the Treasury point of view as to how much the inventors of the United Kingdom could be made to contribute to the taxation of the country. Rather let them take the broader and more enlightened views which were suggested by reference to the grants in aid of technical education; by the representations which had been made in so many memorials, letters, and pamphlets in the interest of inventors, advocating the reduction of these renewal fees not merely for the benefit of inventors, but for the advancement of our trade and manufactures, the employment of our people, and the prosperity of the country at large.

Sir W. HARCOURT said a few words in support of the motion.

Sir M. HICKS-BEACH said that in this matter the first question which the Government had to consider was what they could afford to do. He did not suppose that the hon. member, or the right hon. gentleman, would argue that the cost of the Patent Office ought to be charged upon the general taxation of the country. Patentees, he thought, should certainly provide for the cost of the office. On the other hand, he did not think that the country ought to look upon the Patent Office as a permanent source of income. After the change introduced in 1883, when the Bill of the right hon. member for West Birmingham was passed, the gross receipts from the Patent Office sank to £88,000, the receipts previously having been much larger. The large increase in the sum derived from patent fees was a matter of very recent growth indeed, and in 1886 there was actually a deficit of £2,800 in connection with the Patent Office. The estimated surplus for 1891 was £116,500, and the Government contemplated very considerable expenditure for the benefit of the service. He had thought it right to examine thoroughly the buildings in which the work of the office was done, and any more inconvenient buildings, both for the gentlemen employed and the public, he had never seen. Complete reconstruction would be necessary, and it would cost fully £130,000. The money would be very well spent, because the rearrangement would facilitate a more efficient and economical administration of the office, and after the reconstruction the public, who frequented the office in large numbers, would have easier access to the specifications and to all the publications in the library. The expenditure would be provided for out of the surplus of the next two or three years. It was also very necessary to make more rapid progress with the work of the abridgment of specifications. Copies of the actual specifications were sent round to a certain number of public libraries, but only in very few places could they be turned to any public use. The public generally wanted abridgments, and to proceed with their preparation more rapidly would involve further expenditure, which must come out of the surplus from the Patent Office fees. The fact that this expenditure must be incurred being admitted, he was ready to acknowledge that there were grounds for considering whether something might not be done in the direction of the reduction of fees. It was not quite right to compare the fees charged here with those charged in the United States, and he, for one, would be very sorry to see the adoption in this country of the United States system, under which, by the payment of £7. 10s., a patentee could obtain protection for 17 years. It was his opinion that the right hon. member for West Birmingham introduced an admirable system by the Act of 1883, when he provided that protection should be given for four years on the payment of £4, and that if the patentee should require further protection he should be asked to make larger payments, year by year, until the total period of 14 years was completed. He thought that in any scheme of revision the system of making a small demand for the first years and of increasing the payment for the later years should certainly be adhered to. Comparison had been made between the total payment exacted in this country for 14 years—namely, £154—with the payment of £77 exacted in the United States. Ours, however, was not the highest payment required to be made, for in Germany the total sum paid for a protection of 15 years amounted to £265. It had been said that these patent fees constituted a tax upon invention. He denied that that was the fact when the payment was light for the first few years. A payment of £4 for four years could not be regarded as a tax upon invention. It was a lower payment than was demanded by any other European country for protection for a similar period. His view was that they should consider whether a reduction might not be made in the fees charged in the interval between four years and eight years, so as to extend the chief protection now given for four years to a considerably longer period. He did not believe that it would be to the advantage of the public, or even of inventors themselves, that patentees should retain patent rights with regard to patents which were not worked, and which were not likely to be worked. Such retention would be as great a hindrance to invention as anything that could be imagined. If a patent was not taken up in a period of seven or eight years, was it likely to be taken up at all? If it was taken up, the fees charged were trivial, as compared with the profits of the successful patentee. What had to be considered, then, was the position of the patentee who did not work his patent, and he thought that what should be done was to make the fees low for a certain number of years, during which the patentee could look about for opportunities to work his patent, but they ought not, by lowering the subsequent fees, to encourage him to retain his patent rights for a longer period. He trusted that the hon. member for Dundee would be satisfied with the statement which he had been able to make.

Mr. LENG expressed his gratification at the assurance given by the right hon. gentleman that he would consider the expediency of extending the period when low fees were charged. As to the proposed reconstruction of the Patent Office, he did not think that any one would grudge the expenditure.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 8, 1891.

Electric Traction Motors.—Electrical news is rather scarce just now. The large companies are for the most part working hard, and business is excellent, although very little fuss is being made about the work that is accomplished. Electric railroad work is booming as usual, the Thomson-Houston Company alone producing motors at the rate of nearly a hundred a week. Practically, all of these motors are of the single reduction gear type brought out this last spring, and they have been meeting with very considerable success. The gearless motors of which so much has been said are being introduced fairly rapidly, although no roads equipped with them are at present completed. A few weeks, however, will see this condition of affairs changed, and it appears at present as if everybody was keeping quiet and waiting to see what the outcome of the gearless motor experiment will be. Among electricians the type meets with approval, though the general opinion seems to be that it will fail either in efficiency or in torque; in other words, that there is nothing sufficiently radical in the design employed to give the powerful torque necessary for work on steep grades without very seriously lowering the efficiency. Of course, for comparatively level roads this objection does not hold true.

The Electric Lighting Plants of the New Naval Vessels.—Some considerable difficulties have been met in fitting electric light plants to the new naval vessels; the gunboat "Concord," in particular, has been the source of considerable trouble. The plant installed was an Edison multipolar marine dynamo, with direct connected engines, and it worked in a rather unsatisfactory manner. The problem of ship lighting is by no means an easy one when space is so contracted as in a man-of-

Digitized by Google

war, but one would suppose that by this time sufficient experience would have been gained in the dessigning of marine dynamos to avoid anything of a serious nature.

The Montreal Meeting of the National Electric Light Association.—Great preparations are being made for the meeting of the National Electric Light Association, in Montreal, the second week in September. There will be a fine display of electrical apparatus and appliances. All the large companies and most of the small ones will send exhibits, and will crowd the large hall that has been provided for that purpose to the uttermost. Besides this, the most hospitable preparations have been made by the Canadians for the reception of their visitors, and there is every probability that the coming Convention will be a great success. At the meeting in Providence, last February, a new and particularly active set of officers was elected, with the best results as regards the efficiency of the association.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *July* 13, 1891.

On the occasion of the voting of the extraordinary credit of 5½ million francs for the Marseilles-Tunis and Marseilles-Oran cables, there was considerable divergence of opinion as to the manner in which the work should be carried out. The committee demanded that the cables should be manufactured and laid by the State, the Government proposing to put the work up to tender. In the end the Government had its way by 317 votes to 162.

The affairs of the Compagnie Continentale Edison do not seem very prosperous just at present. The *personnel* is being constantly changed. M. R. V. Picou, consulting engineer to the Company, has severed his connection with it. M. René Arnoux has been appointed works manager at Jury, and most of the staff have been or shortly will be altered.

The Société Générale des Téléphones continues its campaign against infringers of its patents. Since the recent judicial decision giving it the monopoly of the telephone transmitter and induction coil, the Company has made several raids on shops where infringing telephones were being constructed without proper licence. The Post Office authorities thereupon adopted the Roulez apparatus. The Company, not to be beaten, has now proceeded to impound all the Roulez instruments it can lay its hands on. Fresh litigation is, of course, inevitable.

The Industrial Exhibition at the Palais de l'Industrie will open in a month's time. Electricity will be very much to the fore. Several large firms are bent on demonstrating the advantages and uses of small electric motors. The gas interest are also exerting themselves, and a large amount of space has been allotted to regenerative lamps, gas engines, gas stoves, &c. The rival systems will have their stands facing one another on opposite sides of the hall. The manager of the electrical department is M. D. Augé, representative of the Khotinsky Lamp Company.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *July* 13, 1891.

The proposed new trunk line between Vienna and Trieste is being pushed on, and the route is being surveyed. It has been decided to complete this line by 1892. The other trunk lines are being used more than expected; the Vienna-Prague line cannot satisfy the demands made upon it, and it is proposed to erect a second line next year. The receipts amount to as much as 900fl. on some days. Constant additions are being made to all exchanges in Austria. The Vienna Company and the Telephone Company of Austria have now over 8,000 subscribers, the Government about 1,500.

Fiume was splendidly lit up by the International Electric Company of Vienna on the occasion of the Emperor's visit to the British Fleet. The huge wheat elevator had very large lights, and looked like a monster beacon, and was also worked entirely by electricity. The search lights and electric arrangements of the British war ships were much admired; but the absence of the Sellner glow lamp signalling apparatus, introduced into the Austrian Navy some years ago after exhaustive trials, was commented upon. The Austrian Navy Department have recently created the posts of "Electro Engineers." First-class engineer, salary £300; second class engineer, salary £200; third-class engineer, salary £180; fourth-class engineer, salary £120.

In Vienna, the International Electric Company are introducing electric motors to the vast number of small master workmen employing from 5 to 20 men in the suburbs; they intend charging about 12 kreuzers (2½d.) per horse-power hour. The town of Zizkow, a suburb of Prague, is to be lit up by the electric light, and the concession has been given to Mr. Krizik, the inventor of the Pilsen-Joel lamp.

CORRESPONDENCE.

QUADRANT ELECTROMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to your criticism on the Paper on "Quadrant Electrometers," by Profs. Ayrton and Perry and Dr. Sumpner, in your issue of June 12th, we beg to state that we have lately turned our attention to the quadrant electrometer, and have been trying, under the guidance of Sir William Thomson, to simplify its parts and adjustments as much as possible. We have been led to do this mainly from the consideration that Sir William Thomson has provided in his series of direct-reading multicellular and other electrostatic voltmeters a much more convenient and less costly means of measuring potential above 40 volts, whether on direct or alternating circuits, than can be obtained by the *idiostatic* use of the quadrant electrometer. Our desire has been to recommend the use of these later direct-reading instruments for all measurements of potentials above 40 volts, and to reserve the quadrant electrometer mainly, as hitherto used *heterostatically*, with the jar kept at a constant potential by the replenisher, for the measurement of small differences of potential in the determination of capacities, insulation resistances, &c. In these uses of the instrument the objections mentioned in the Paper do not in any way interfere with its accuracy or convenience. As Prof. Ayrton and his colleagues have pointed out that the action of the supports of the lower part of the guard tube would interfere with the use of the instrument for certain purposes, we have, acting under Sir William Thomson's advice, arranged to dispense with these supports and the lower part of the tube altogether.

As regards the system of magnetic control mentioned in the Paper, a great deal of time was spent upon this by Sir William Thomson in some of the earlier forms of the instrument, but the system was abandoned, as it was found inconvenient in many respects. We have, therefore, always adhered to the present bifilar system of control, which is very convenient for all degrees of sensibility, is particularly well adapted for the highest degrees of sensibility, and is perfectly free from all disturbances from magnets or any other influences external to the instrument.—I am, Sir, &c.,

JAMES WHITE.

Glasgow, July 14, 1891.

ALTERNATING CURRENTS FOR TRAMWAY WORK.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice that it is being stated that M. Zipernowski has invented a combined system of utilising continuous and alternating currents with the idea of working an electric tramway in Vienna, the method being to carry a high tension alternating current from a distance, to drive a synchronising motor, which drives a continuous current dynamo to supply the motors of the tramcars.

Without in the least wishing to take away any credit due to M. Zipernowski, I wish to state that the working of the Buffalo City tramways from the Falls of Niagara in this way formed part of the scheme which I presented to the International Niagara Commission last year. As the Cataract Construction Company has not yet settled what, if any, electrical project is to be adopted at Niagara, I do not desire to make any further statement at present.—I am, Sir, &c.,

GEORGE FORBES.

Athenæum Club, July 13, 1891.

LEGAL INTELLIGENCE.

City and South London Railway Company v. London County Council.

In the Court of Appeal, on Friday, the case of the City and South London Railway Company *v.* London County Council came before Lords Justices Lindley, Fry, and Lopes, in the form of an appeal by the London County Council from a judgment of Justices A. L. Smith and Grantham, sitting as a Divisional Court, setting aside an order by the Lambeth police magistrate directing the City and South London Electric Railway Company to pull down so much of their Kennington Park-road station as overstepped the general building line. It appeared that when the station was erected the jurisdiction under the Building Act was vested in the Metropolitan Board of Works, and that their sanction was not obtained for the erection of the works which the police magistrate had directed to be pulled down. The case raised certain questions affecting the private Acts of Parliament of all railway companies passing through London, one being whether the special powers conferred by such Acts cancelled the prohibition by the general Act of erecting buildings in front of the general building line without the consent of the local authority. The plaintiff Company, under Acts obtained in 1884 and 1887, took powers to construct an underground electric railway from King William-street to Stockwell, and to purchase various plots of land for the purpose of erecting stations. In Kennington Park-road they extended their station to the line of the pavement. The London County Council complained of this, and the magistrate held that it was not necessary for the purposes of the railway that any part of the station should be beyond the general building line, and ordered the demolition of that part which overstepped the building line That decision was reversed, and from that reversal the County Council now appealed. Mr. Lumley Smith, Q.C., and Mr. R. C. Green appeared for the London County Council in support of the appeal, while Mr. Finlay, Q.C., and Mr. W. Graham opposed it on behalf of the City and South London Electric Railway Company. Their lordships upheld the decision of the Divisional Court, and dismissed the appeal with costs.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all, Vol. I., 20; Vol. II., 18), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

TENDERS INVITED.—The Burton-upon-Trent Town Council invite tenders for an efficient system of electric lighting for adoption in certain streets in the borough, and for the construction and erection of a central station for generating electricity, and for supplying and laying down the necessary electrical wires, insulators, &c. Further particulars will be found in our advertisement columns; and forms of tender, conditions, and specifications may be obtained on application to Mr. F. L. Ramsden, engineer, Gas Works, Burton-upon-Trent. Tenders have to be delivered to Mr. T. N. Whitehead, the town clerk, before 10 a.m. on Saturday, August 29th.

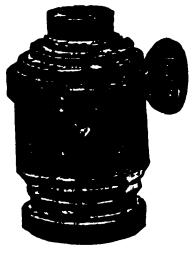
——— As will be seen by our advertisement columns, the Corporation of Salford invite tenders for lighting the Ladywell Sanatorium by electricity. Applications for specifications are to be made to Messrs. Maxwell and Tuke, or to Messrs. E. and F. Hewitt, architects, Manchester. Tenders must be addressed to the Chairman of the General Health Committee, and delivered to Mr. S. Brown, the town clerk, Salford, not later than 11 a.m. on Thursday, the 30th inst.

TENDERS ACCEPTED.—The tender of Messrs. Comyn, Ching and Co. has been accepted by H. M. Commissioners of Works for the pneumatic and electric bell hanger's work in the London district, at 25 per cent. off schedule prices for materials, &c., and 7½ per cent. on rates of wages in day work. The other tenders were:—Young and Buss, 37½ off, 15 on; C. E. Zimdars, 33⅓ off, 25 on; McClellan and Co., 25 off, 25 on; J. Defries and Sons, 20 off, 9 on; H. F. Joel and Co., 20 off, 15 on; J. and G. Odhams, pneumatic 10 off, 10 on, electric 25 off, 10 on; J. T. Mayfield and Co., 10 off, 10 on.

LISBURN.—The only tender received in response to the invitation of the Town Commissioners for estimates for lighting the town by electricity or gas, was from the Lisburn Gas Company, whose offer was 2s. 2d. per lamp, but the acceptance of the tender has been postponed, owing to the increase in the price.

SALE BY AUCTION.—Messrs. J. M. Klenck and Co. announce in our advertisement columns that they will sell by auction, at Storks-road, Bermondsey, S.E., on Thursday next, the 23rd inst., a saw-mill plant, machinery, &c., including a 25 H.P. horizontal steam-engine, a nearly new double furnace Galloway boiler, donkey pump, steam piping, 30 H.P. semi-portable engine and boiler by Davey, Paxman and Co., &c., &c.

THE PAISTE SWITCH.—Mr. Reyrolle, who is well known to our readers as the maker in this country of the Paiste Switch, sends us an illustration, which we give herewith, representing the switch inside an Edison lampholder. This is an ingenious and useful device. Of course the combination is made for export only. In addition to manufacturing this switch on a large scale, Mr. Reyrolle is an electrical and general engineer, maker of all kinds of electrical apparatus, switch boards, &c., &c., amongst which we may mention the one at the Metropolitan Electric Supply Company's Sardinia-street Station, which was recently fully described by Dr. Fleming in the columns of *The Electrician*.



ACORN AND EDISON SCREW KEY SOCKETS.—Messrs. Bayley Bros. ask us to notify that they are the original makers in this country of these key sockets, and are the only firm in the United Kingdom now making them.

ELECTRIC BLOWERS FOR VENTILATING STEAMSHIPS.—Messrs. Shippey Brothers inform us that they have secured the contract for fitting the new war ships, now being built in France for the Chilian Government, with "Standard Electric Blowers."

MESSRS. KING, MENDHAM AND CO.—On Thursday, last week, the *employés* of this firm had their annual outing at Ilfracombe, the party numbering between 60 and 70.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

June 3, 1891.

9,403. J. RAEBURN, junr. Glasgow. Improvements in electrically insulating appliances, known as "suspensions."

9,423. H. H. GRENFELL. London. An improved holder for electric incandescent lamps.

9,435. E. F. H. H. LAUCKERT. London. An electrical transformer.

9,436. A. D. WILLIAMSON. London. An electrical transformer.

9,437. J. VON PEICHL. London. Improvements in compasses with electrical appliances for signalling and recording the course and speed of a ship, also partly applicable to other purposes.

June 4, 1891.

9,462. A. W. ALCOCK. Manchester. An electro-static switch and phase indicator.

9,507. C. A. DAYTON. London. An improved electric stop motion for engines.

9,522. W. STANLEY, junr., and J. F. KELLY. London. Improvements in alternating current electro-magnetic motors.

9,524. W. STANLEY, junr., and J. F. KELLY. London. Improvements in methods of, and apparatus for preventing the interference with speech on telephone circuits by induced and other currents.

June 5, 1891.

9,555. J. E. A. GWYNNE. London. Improvements in carbons or electrodes for arc or other electric lamps.

June 6, 1891.

9,593. J. T. NEWELL. London. Advertising and illuminating by electric current.

9,606. W. P. THOMSON. Liverpool. Improvements in apparatus for holding telephone receivers, and for placing in or out of circuit either the call or the transmitting apparatus (S. Stein, junr., Germany).

9,627. C. D. ABEL. London. Improvements in thermo-electric batteries (R. J. Gülcher and the firm of J. Pintsch, Germany).

9,628. D. G. FITZGERALD. London. Improvements in or connected with negative elements (positive electrodes in charging secondary cells) of voltaic batteries.

9,629. D. G. FITZGERALD. London. Improvements in or relating to the negative elements (positive electrodes in charging secondary cells) of voltaic batteries.

9,637. H. ALABASTER and T. E. GATEHOUSE. London. An improved automatic electric control or cut-out.

9,639. W. C. LOVELACE. London. The better insulation of electrical conductors, and to obtain immunity from fire from the use o such conductors.

9,642. H. WATT. London. Improvements in and relating to electric lamps or lighting apparatus.

Digitized by Google

June 8, 1891.

9,652. A. Watt. Balham. Improvements in the production of copper tubes by electrolysis.

9,683. T. J. D. Rawlins and A. Walker. London. Improvements in electric primary batteries.

9,689. P. Jeanty. London. Apparatus for supplying depolarising or other liquids to a series of electric batteries.

June 9, 1891.

9,734. W. Aldred. Sheffield. Improvements in dynamic electric machines.

9,762. S. C. C. Currie. London. Improvements in secondary or storage batteries.

9,779. M. F. F. Bellier. London. Application of vibrating tongues to produce automatic resistances in telegraph lines.

9,780. P. V. McMahon. London. An electric regulator.

9,791. J. Greenwood. London. Improvements relating to carbon electrodes for electrolytic and other purposes.

9,803. An improvement in galvanic batteries.

June 10, 1891.

9,817. A. R. Molison. Swansea. Improvements in apparatus for inducing electric sparks for gas lighting and like purposes.

9,868. J. Orme. London. Improvements in or connected with electrical signalling to and from trains.

9,876. D. C. Coombes and W. Rowe. London. Improvements in telegraph block systems of railway traffic control.

June 11, 1891.

9,915. J. Swinburne and H. S. Holt. Teddington. Improvements in electric measuring instruments, electric safety fuses, manufacture of incandescent lamps, telephone transformers, electric organs, transformer distribution, envelopes.

9,928. G. A. Schoth. London. Improvements in galvanic batteries.

June 12, 1891.

9,955. S. H. Holden. Birmingham. An improved electricity meter.

9,956. R. H. Housman. Bromsgrove. An improved electricity meter.

9,997. J. Armstrong. London. Improvements in pipes or tubes for conveying liquids and gases, and for protecting and insulating electric conductors, and for other like purposes.

10,016. A. G. Melhuish. London. A new or improved dynamo-electric motor or generator.

10,023. W. P. Thomson. Liverpool. Improvements in or relating to telegraph relays (R. O. Wickes, United States).

10,030. C. Rieger. London. An improved device for obviating sounds produced by the vibration of electric conducting wires.

June 13, 1891.

10,069. A. Hoster. London. Improvements in or relating to electric bells.

10,082. P. Jablochkoff. London. An improvement in voltaic batteries.

10,083. H. S. Keating. London. An electrical safety cut-out.

10,090. L. Graban. London. An improved process for the electrolytic production of aluminium.

June 15, 1891.

10,260. A. Shiels and W. Elliott. Glasgow. Improvements in and connected with electric signalling and lighting in trains, said improvements being also applicable for telegraphic and telephonic communication.

10,280. W. I. Thompson. Liverpool. Improvements in devices for protecting the ears when using telephone receivers. (R. Kolbe and K. Lischka, Germany).

10,289. W. Greenhalgh. Leeds. Improvements in mechanism for actuating fans or punkahs by electricity.

10,302. C. R. Bonne. London. New or improved coin-freed or automatic electro magnetic induction apparatus. (Petsch, Kupka and Popp, Austria).

10,307. C. Coerper. London. Improvements in and relating to dynamo-electric machines and electric motors.

10,311. H. G. Watel. London. Improvements in electrically driven fans.

June 18, 1891.

10,347. D. Fitzpatrick. London. Improved electric battery.

10,364. A. B. Gill. London. Improvements in electrical switches

10,371. F. R. E. Branston. London. Improvements in the production of light and the generation of heat and electricity.

10,398. J. S. Lewis. London. Improvements in telephone transmitters.

June 19, 1891.

10,425. F. W. Dickenson. London. Improvements in or relating to means or apparatus for illuminating roundabouts and the like with electric light.

10,434. P. E. Singer. London. An electric metre.

10,451. W. Haywood and C. H. Driver. London. An improvement in posts for carrying electric lights and such like purposes.

June 20, 1891.

10,481. G. A. Cassagnes. London. Improvements in apparatus for synchronising electric telegraph instruments.

10,548. W. Sharrow. London. Improved apparatus for mechanically winding electrical wires.

10,554. S. Z. de Ferranti. London. Improvements in connection with the construction and working of transformers or converters.

June 22, 1891.

10,612. Siemens Bros. and Co. Ltd. London. Electrical transformers for rotary phase currents. (Siemens and Halske, Germany).

10,613. Siemens Bros. and Co. Ltd. London. Glow lamps for rotary phase currents. (Siemens and Halske, Germany).

June 23, 1891.

10,636. M. A. Weir. Kingston-on-Thames. Improvements in electric telegraph printing.

10,664. H. J. Harris. London. Improvements in or connected with the insulation of electrical conductors.

10,695. E. E. Angell. London. An improved method of and apparatus for heating metal bars or blanks by electricity, for forging and other purposes.

10,697. H. H. Lake. London. An improved method of and apparatus for protecting dynamo-electric generators and other apparatus from the effects of lightning. (The Thomson-Houston International Electric Company, United States).

10,703. H. C. Jobson. London. Improvements in the manufacture of the arms or attachments of telegraph poles for carrying insulators.

10,704. A. Douglass. London. Electric directing apparatus for use in cabs, carriages, or on boats, railway trains and the like.

June 24, 1891.

10,729. G. B. Lückhoff and E. H. Hungerbühler. London. Dynamo or electro-motor ring armature construction.

10,762. G. J. Cashmore. Birmingham. Improvements in call boxes or like electrical communicators.

10,778. J. A. F. Aspinall and H. A. Hoy. London. Improvements in electric arrangements and apparatus for locking railway signal and point levers, also applicable for other purposes.

10,787. G. A. Cannot. London. Improvements in materials for insulating electric conducting wires, and for carbons and incandescent filaments for electric lighting.

June 25, 1891.

10,821. W. Balch. London. Improvements in firing guns by electricity.

10,832. Woodhouse and Rawson United (Limited). London. Improvements in electrical transformers. (E. Preschlin, Germany).

10,838. W. Brew. London. Improvements relating to the lighting of trains by electricity.

10,839. W. Brew. London. Improvements relating to dynamo-electric machines, and to electro motors.

10,843. J. Ferrand. London. Improvements in apparatus for regulating electric currents.

10,860. R. J. Spreadbury. London. Improvements in means or mechanism for regulating the lighting intensity of electric lamps.

June 26, 1891.

10,894. C. V. Boys. London. Electrometers.

10,932. A. B. Gill. Lee. Improvements in apparatus for repairing commutators of dynamos.

10,933. A. B. Gill. Lee. Improvements in commutators of dynamo-electric machines.

10,934. J. A. Kingdon and A. B. Gill. London. Improvements in dynamo-electric machinery, and in the regulation thereof.

June 27, 1891.

10,939 H. A. Mavor, W. A. Coulson, and S. Mavor. Glasgow. Improvements in conductors for electric lighting, electric bell circuits, and like purposes.

10,969. W. Aldred. Sheffield. Dynamo-electric machines.

10,977. A. de Meritens. London. Improvements in galvanic batteries. [Date applied for under Patents Act 1883, Sec 103, 28th November, 1890, being date of application in France.]

10,978. Siemens Bros. and Co., (Limited). London. Improvements in insoluble porous anodes for electrolytical process. (Siemens and Halske Germany).

10,983. J. H. Nicholson and The Aurophone Company, (Limited). London. The electro medication belt or pad.

11,004. C. Rousseau. London. Improvements in and relating to the manufacture of plates for electric accumulators.

COMPANIES' MEETINGS & REPORTS.

The Eastern Telegraph Company (Limited).

The thirty-eighth half-yearly ordinary general meeting of this Company was held yesterday, at Winchester House, Old Broad-street; Sir John Pender, K.C.M.G., presiding.

The SECRETARY (Mr. George Draper) read the notice convening the meeting, and the minutes of the last ordinary general meeting, which were confirmed.

The report of the Directors being taken as read,

The CHAIRMAN said that the receipts for messages during the six months ended March 31, 1891, amounted to £349,749, as against £348,624 for the corresponding period of 1890, showing an increase of £1,125. The total working expenses for the half-year amounted to £102,020, as against £98,477, an increase of £3,543. Included in these figures, however, was the item "special repairs to the Alexandria-buildings, £3,823," to which he referred at the last meeting. Several of the items showed an increase, while others showed a decrease. The general expenses in London were £9,503, against £8,726, or an increase of £777, the principal amounts being for advertising and stationery. The working expenses at stations amounted to £75,003, as against £72,677, or an increase of £2.326. The necessary increase in the number, and the additional pay and allowances granted to some of their foreign staff, to which he referred at the last meeting, accounted for the increase in salaries, rent, fuel, and light. The amount carried to maintenance ships' reserve fund was only £3,000, as against £5,000 in the corresponding half-year, the other portion having been contributed by those telegraph companies who had hired their ships during the half-year. All their ships were now in a thorough state of repair. The staff endowment assurance fund was £2,366, against £1,168, or an increase of £1,198. Up to the last year a certain number only of their staff had taken advantage of this assurance scheme. The Directors, however, after 10 years' experience of its working, were so convinced of the benefits it conferred on the staff that they urged the remainder to join, and he was pleased to say that nearly the whole of the staff were now contributing members. It was a most important thing for the *employés* of the Company. The expenses attending repairs and renewals of cables amounted to £53,144, against £47,320, or an increase of £5,824. On reference to abstract "C," page 7, of the accounts, full particulars would be seen of the work performed by their ships during the half-year. The chief expense had been incurred in connection with the Red Sea cable, laid in 1879. They had succeeded in the removal of all the known weak parts, and laid in new cable, and it was now believed that this line, which had been working since the formation of the Company, could still be kept efficient for a number of years, thereby increasing the security of telegraph communication in the Red Sea. After providing for all expenses and interest charges against revenue, they were able to recommend a final dividend at the rate of 5 per cent. per annum, and a bonus of 1½ per cent. for the year ended March 31st last, and carry £96,000 to general reserve fund, which amounted to £534,650, after the appropriation of £100,000, to the cost of Suez-Perim-Aden No. 4 cable. He thought they would agree with him that this was a very satisfactory state of things. At the meeting last July he showed them the necessity of laying a new cable in the Red Sea from Suez to Perim and from Perim to Aden, at a cost of about £250,000. At the general meeting, in January last, they were informed that, in anticipation of the largely-increased traffic with Australia, consequent on the reduction of rates between Europe and certain Australasian Colonies, they had decided to lay a triplicate cable between Aden and Bombay of such a capacity as would give them a considerable margin of carrying power to deal with any increase of traffic that might be at all likely to take place during the next few years. It had always been their policy to keep ahead of the carrying requirements of the Company, and it was satisfactory to be able to say that the encouraging results of the traffic since the reduction of the rates to Australia had fully justified the prompt action of the Directors. With the temporary assistance of the Eastern and South African Company, in which they held 59/60ths of the share capital, they would be able to meet the payments as they fell due to the contractors without, to a very large extent, disposing of their reserve fund investments. The financial transactions would take four years to complete, and it was estimated that at the end of that time their position would be that the additions would have been paid for, and the whole amount applied out of the reserve fund, the Eastern and South African Company would have been repaid, and their capital account would stand at practically the same figure as at present, provided, of course, that no further extensions of their system were considered advisable. It was hardly necessary for him to say that the Company would then be in a much better financial position than it was to-day. Having referred with satisfaction to the steadily growing South African traffic, and to the general efficiency of the whole of the Company's system of cables, he concluded by moving the adoption of the report and the payment of the dividend recommended on the preference shares and the bonus on the ordinary shares.

The MARQUIS of TWEEDDALE seconded the resolution.

The CHAIRMAN, in reply to Captain Goodsall, said that, by the advice of their engineers, the last Aden-Bombay cable was laid to the south of the existing one.

The resolution was then put to the meeting, and carried unanimously.

On the motion of Mr. GRIFFITHS, a vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN having briefly acknowledged the vote, the proceedings terminated.

[*A full report of the meeting will appear in next week's issue.*]

The following is the report of the Directors of this Company for the half-year ended March 31st last, referred to in the above report:—

The revenue for the period amounted to £383,306. 18s. 2d., from which are deducted £102,020. 10s. 4d. for ordinary expenses and £53,144. 9s. 6d. for expenditure relating to repairs and renewals of cables, &c., during the half-year. After providing £2,274. 12s. 9d. for income-tax, there remains a balance of £225,867. 5s. 7d., to which is added £78,195. 6s. 5d. brought from the preceding half-year, making a total available balance of £304,062. 12s. From this amount there have been paid—

Interest on debentures and debenture stock	£28,274	13	2
Dividend on preference shares	20,474	3	1
An interim dividend of 1¼ per cent. on the ordinary shares	50,000	0	0
	£98,748	16	3

Leaving a balance of £205,313. 15s. 9d., from which £95,000 has been carried to general reserve.

The Directors now recommend the declaration of a final dividend for the year ended March 31st last of 2s. 6d per share, and a bonus of 3s. per share, amounting together to £110,000, both payable on the 16th instant, free of income-tax, and making, with the three previous payments on account, a total distribution of 13s. per share, or 6½ per cent. for the year, on the ordinary shares. The balance of £313. 15s. 9d., shown at the foot

Digitized by Google

of the revenue account, is proposed to be carried forward to the next half-year.

The revenue includes £33,283. 4s. dividends and bonus for the half-year upon the Company's investments in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies.

The agreement with certain of the Australasian Colonies for the reduction of rates between Europe and Australia having been concluded, the new rates were brought into operation on May 1st last, and the increase of traffic is encouraging.

The laying of the triplicate cable between Aden and Bombay, referred to in the last report, was completed by the contractors on April 19th last. The operations for duplicating the Suez-Suakin section, referred to in the last report, were successfully completed on April 10th last.

The Chili Telephone Company (Limited).

An ordinary general meeting of this Company was held at Winchester House, Old Broad-street, on Tuesday, under the presidency of Colonel R. Raynsford Jackson.

The SECRETARY (Mr. Edmund Petley) having read the notice convening the meeting, the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, I need not say much in support of the report, because all the main features of our business are fully dealt with in it. My object, however, will be to emphasise what is stated there, and, perhaps, to add to its clearness on one or two points I will ask those who have reports in their hands to look at page 7, and to the statement of figures there. You will find that the gross revenue of the Company has increased from £26,310 to £38,711, or 47 per cent., and that the working expenses have increased from £15,996 to £19,506 –only 22½ per cent. The cost of working, if you go through the calculation, you will find has fallen from 61 per cent. on the gross revenue to 50 per cent. The increase, therefore, of the gross revenue and the diminution in the ratio of the expenditure have led to an increase of the net revenue in Chili from £10,314 to £19,205, showing the very satisfactory increase of 86 per cent. These figures will make manifest the pleasing feature in the statements we have to put before you—that is, the great improvement in the value of our property in Chili, the increase in its earning power, and, the fact that, but for an adverse circumstance over which we have had no control, we should have been able to pay, wisely and prudently, a handsome dividend this year, in addition to adding a fair sum to the reserve. We have been obliged to diminish the profit made upon the working of £17,094 by £3,089, which is a reduction on the present value of our liquid assets in Chili due to the fall of exchange, that diminution being 25 per cent. If it had not been for that fall in exchange, our earnings would have been equal to 8½ per cent. upon our capital. You will remember that last year I expressed my regret that we were only able to pay to our shareholders 5 per cent., though, in our prospectus, we held out the hope that we should be able to pay a dividend of 6 per cent. So far as our enterprise is concerned, we should now be able to exceed very much the promise of our prospectus, but for the fact that our prosperity has been—I trust only temporarily—interrupted by the civil war in Chili. Before I touch further upon the consequences of the civil war, I wish to point out that there has been an increase in the number of our subscribers in Chili of 965, or 33 per cent. I will ask you now to turn your attention to the table of expenditure in the last sheet in the report, showing that we have spent during the year £35,136, and I wish to point out that 75 per cent. of that amount has been spent in Santiago and Valparaiso alone. It has been spent upon the entire reconstruction of the systems there, upon the assimilation with our own of the property we took over from the National Company of Chili, and upon trunk lines between the political and commercial capitals of Chili. This will be eventually of enormous value in the development of our system in those two towns. The civil war in Chili has affected us in a variety of ways. In the first place the President found it expedient to monopolise the use of our telephonic exchanges in the territory over which he maintains his rule, and we have received for the loss which we thus sustained a certain, but undoubtedly not an adequate, compensation. We trust that, when the civil war is over, we shall obtain ample compensation for all our losses arising out of the revolutionary war, from whichever party gains the ultimate ascendancy. In the territory under the control of the Congress party our subscribers have not been dispersed. We are still working our own exchanges, and what damage has been done to our property in Chili has been in those parts of the Republic where the actual battle has raged. What the loss will prove to be in the end we are unable to say, but it is satisfactory to know that we are entitled to compensation for it. Another consequence of the civil war has been the enormous fall in the exchange, which has gone further since the accounts were made up: and also the absence of all knowledge as to when the normal state of healthy government will be restored in Chili. Until then, we can form little idea of when and how far the cessation of the war will restore to us our subscribers and enable us to extend our operations as has been done in the past year. Our doubt upon these and other subjects has led us to the conclusion that, although we have earned what would, under ordinary circumstances, have enabled us to pay 7 per cent., it is wise not to declare a dividend. If the war should cease early, and if the position of affairs in Chili should then be hopeful and satisfactory, it is quite possible that we may, even at an abnormal time, declare a dividend, for there is nothing in our articles to prevent our doing so. I have confidence that the shareholders will regard the course which the Directors recommend to them as a wise and prudent one. The Company is soundly based, the shareholding body is a strong one, and I think our position is exactly one of those which justifies our thinking more of the future than of the present. I do not regard it as necessary, having touched upon these points, to do more than to ask you to pass the resolution which I now propose:—

"*That the Report of the Directors, with the Statement of Accounts to the 31st March, 1891, now presented to this meeting, be approved and adopted.*"

The VICE-CHAIRMAN (Mr. Thomas Greenwood) briefly expressed his pleasure at seconding the resolution.

The CHAIRMAN put the motion to the meeting in the usual way, and declared it carried.

Mr. GREENWOOD: The Chairman is so very well known (not only to you, but to the world at large) in all telephonic business, that I need only ask you to re-elect him to his seat on the Board, which he has admirably filled since the commencement of the Company.

Mr. ALEXANDER HENDERSON seconded the resolution, which was unanimously adopted.

On the motion of Mr. A. HENDERSON, seconded by Mr. E. E. VENABLES, Mr. Thomas A. Welton was re-elected auditor to the Company.

The CHAIRMAN then intimated that the business was concluded, and he thanked them for their attendance.

Mr. VENABLES proposed, and Dr. LEESON seconded, a vote of thanks to the Chairman.

The motion was unanimously agreed to.

The CHAIRMAN: I beg to thank you, gentlemen, and I hope that the next time we meet it will be under favourable circumstances all round, instead of only in one very important particular.

The proceedings then terminated.

Johannesburg Gas Company (Limited).

An extraordinary general meeting of this Company was held at the Cannon-street Hotel, E.C., on Wednesday afternoon, Mr. W. F. Lance presiding, "for the purpose of considering certain proposals for the dissolution of this Company, and the transfer of its assets and rights to a company, to be formed in the South African Republic, for the lighting of the town of Johannesburg by gas and electricity respectively; or, otherwise, for the purpose of considering proposals in connection with the acquisition by this Company of the said concession for lighting by electricity, and the increase, if necessary, of the capital of this Company, or the issue of reserve shares, in consideration for, or in connection with, the acquisition of the said concession for lighting by electricity; and for the purpose of adding to, repealing, or altering any of the provisions of the Articles, in such manner as may be found expedient in connection with the said acquisition, or otherwise."

The SECRETARY (Mr. Taffs) having read the notice convening the meeting,

The CHAIRMAN said that the object of the meeting had reference to the first portion of the notice which had just been read, namely, the consideration of a scheme in connection with the suggested dissolution of the Company, and the formation of a new company for the acquisition of the electric lighting concession for Johannesburg. After briefly reviewing the circumstances which have led up to the present position of the Company, the Chairman dealt with the subject of his journey to South Africa on behalf of the Company, and said that, on arriving at Johannesburg, he found that the electric lighting concession was about to be taken up by a syndicate, which would start it in a small way by raising funds sufficient for a plant of comparatively small dimensions, and so make a beginning, which they were able to do within a few weeks—that is to say, there was plant and machinery on the spot for the purpose, so that, had he allowed that to continue, the Company would have had a rival in the field before they were in a position to complete their gasworks. Therefore, under the instructions of the Committee, he took such steps as were open to him, and was enabled to secure, on favourable terms, this electric lighting concession from the original holders of it. In addition to this, they had obtained from the Government of the Transvaal Republic an extension of time for twelve months under the gas concession, but on the distinct condition that they were, in connection with the acquisition of the electric lighting concession, to place a few arc lights in some of the principal streets of Johannesburg. The Government insisted upon this in order to satisfy the public of Johnannesburg, who had, not unnaturally, been crying out for light for some time past. It was, therefore, necessary to authorise the construction of 10 arc lights, which they found could be put in within a week's time, and the order for these had been cabled out to Johannesburg, involving an expenditure of about £2,500. The terms on which the electric lighting concession had been obtained were the payment by instalments of £6,000 in cash, and £8,000 or less in shares, according to the capital of the new company to be created, which would have, under this concession, the monopoly of lighting the town of Johannesburg. The Chairman said he had gone carefully into the figures, and he was sure he was within the mark in telling them that they might safely calculate on a net profit of from £20,000 to £25,000 per annum, which would yield a dividend of upwards of 10 per cent. on a capital of, say, £200,000. Owing to the high price of coal at Johannesburg, the cost of producing the electric light would be little, if any, higher than gas. The Directors proposed to make gas the principal source of lighting, but they also proposed to supply the electric light where required, and in order to lay down the necessary installations for this purpose additional capital to the extent of £50,000 would be required. Various methods had been suggested for raising this money, but the scheme favoured by some of the principal shareholders was the issue of a further £50,000 worth of debentures. In conclusion, the Chairman, in order to obtain an expression of opinion from the meeting, submitted the following resolution, which he explained could not be made valid now as there were not two-thirds of the shareholders represented at the meeting:—

"*That this meeting approves of the dissolution of the Johannesburg Gas Company (Limited) and the formation of a new company as an English*

Digitized by Google

company, to be called the Johannesburg Lighting Company (Limited), for the purpose of acquiring and working the concessions for lighting Johannesburg with gas and electricity respectively, such company to have a share capital and debenture issue together not exceeding £250,000, of which amount the debenture issue, bearing interest at 8 per cent. per annum, and forming a first charge upon the Company's undertaking, and assets shall not exceed £100,000; and it is hereby resolved that upon the registration of such company in England this Company be dissolved, and all its assets and liabilities transferred to the Johannesburg Lighting Company (Limited) in exchange for:—Debentures of the Johannesburg Lighting Company (Limited), £50,000 to be issued to holders of the existing debentures in the Johannesburg Gas Company and ordinary shares of the Johannesburg Lighting Company (Limited), for £65,000 to be issued to the holders of existing shares in the Johannesburg Gas Company (Limited), to be distributed by the Directors as liquidators in the proportion of one share in the Johannesburg Lighting Company for every two shares in the Johannesburg Gas Company (Limited)."

Mr. ANDREWS seconded the motion, which was agreed to, and the meeting was adjourned for a month.

Telegraph Construction and Maintenance Company (Limited).

A general meeting of the shareholders of this Company was held on Tuesday, at the offices, Old Broad-street. Sir George Elliot, M.P., presided.

The SECRETARY (Mr. William Shuter) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, you are aware that we have no accounts to render at these half-yearly meetings, and as regards the work carried out during the last six months, I may say briefly that we have been employed principally since the commencement of the year in completing contracts entered into in 1890—that is, in finishing the manufacture and in laying the Eastern Telegraph Company's cable between Aden and Bombay and the Eastern Extension Telegraph Company's cable between Madras and Penang. Both of these operations were successfully carried out in the months of March and April last. Our factories are still at work—that is, our cable factories, for we have other factories—in completing a contract for the Great Northern Telegraph Company. It is, of course, difficult to forecast with any certainty the prospects of future cable contracts; but we are able to say that our general current business continues to be satisfactory. You are aware that on this occasion, as well as on the occasion of our annual meetings, we never go into details, and we must hope that we shall continue that course which we have practised for the last 20 years, and receive your confidence in the belief that we are doing the best for you in a description of business the nature of which is such that we think its general administration should, in the interests of the Company, be left to the Directors as much as possible. We do not go into our accounts except once a year, and I trust that my observation as to what our policy is will commend itself to the general meeting, and to the shareholders as a body. That is the whole of the business.

After a short pause, and no shareholder rising to ask any question or to address the meeting, the CHAIRMAN added: That is the whole of the business, and it is pleasant for me to infer that my observations have been received with satisfaction by the shareholders.

The meeting then separated.

Edison and Swan United Electric Light Company (Limited).

The following is the report of the Directors to be submitted to the annual meeting, to be held at the Westminster Palace Hotel, on Tuesday next, July 21, 1891, at 12 noon:—

The Directors have the pleasure of presenting to the shareholders their report and the accounts for the year ending June 30, 1891.

The business of the Company has resulted in a credit balance of £72,905. 4s. 7d., out of which the Directors have appropriated the sum of £3,425. 14s. 8d. to meet loss on realisation of dynamo account, taken over at the amalgamation; and £12,371. 14s. 7d. has been absorbed by the payment of an interim dividend on the A shares, at the rate of 7 per cent. per annum, for the first six months of the year. The Directors recommend the payment of the following dividends on the A shares, free of income-tax, and to be distributed in accordance with Clause 87 of the Articles of Association:—

(*a*) At the rate of 7 per cent. per annum for the half-year ending June 30, 1891 (making 7 per cent. for the year),

(*b*) Three per cent. in completion of payment of arrears of cumulative preference dividend for the year ending June 30, 1885,

(*c*) Seven per cent. in payment of arrears of cumulative preference dividend for the year ending June 30, 1886,

which will absorb £47,719. 10s. 7d., leaving £9,388. 4s. 9d., which the Directors have carried to the reserve fund, in accordance with Clause 89 of the Articles of Association.

The Directors have granted licences to several electrical firms and companies to manufacture holders and sockets for incandescent electric lamps under the Company's patents. This branch of the business will increase as electric lighting increases, and will bring a satisfactory addition to the revenue of the Company.

Mr. J. S. Forbes and Mr. F. R. Leyland retire from the Board in rotation, and offer themselves for re-election as Directors. The auditors, Messrs. Welton, Jones, and Co., retire, and are eligible for re-election.

NEW COMPANIES REGISTERED.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—Registered by Ashurst, Morris, Crisp and Co., 17, Throgmorton-avenue, with a capital of £800,000 in £10 shares. Object: To adopt and carry into effect certain agreements expressed to be made between the Brush Electrical Engineering Company (Limited), the Laing, Wharton, and Down Construction Syndicate (Limited), and the City of London Electric Lighting (Pioneer) Company (Limited), of the first part, and the Company of the other part, to carry on in the City of London and in the district of St. Saviour's Southwark, District Board of Works, the business of an electric light company in all its branches; to carry on the business of electricians, mechanical engineers, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity. The first subscribers are:—Sir D. L. Salomons, Broomhill, Tunbridge Wells; F. W. Reynolds, 73, Southwark-street, S.E.; E. Lucas, 40, New Broad-street, E.C.; Duke of Marlborough, 3, Carlton House-terrace; Earl of Suffolk and Berkshire, Charlton Park, Malmesbury; Alan Charteris, Lloyd's, E.C.; J. B. Braithwaite, jun., 27, Austinfriars, E.C. There shall not be less than three nor more than 10 Directors; the first shall be appointed by the signatories to the memorandum of association. Qualification, £1,000. Remuneration: For the years 1891 and 1892, £1,000 per annum; 1893, £1,500; 1894, £2,000; 1895, £2,500; 1896 and thereafter, £3,000; the same to be divisible.

PERKINS, GRAHAM AND CO. (LIMITED).—Registered with a capital of £10,000, in £50 shares, the objects including the construction, carrying out, and equipment of electric light, telephone, telegraph, and electric power supply works.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the past week amounted to £4,883.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The traffic receipts of this Company for the past week amounted to £692.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The prospectus of this Company has been issued this week, the objects being to undertake the electric lighting of the City of London and the district of St. Saviour's (Southwark) District Board of Works. The two Provisional Orders granted by the Board of Trade for lighting the City to the Brush Electrical Engineering Company (Limited), and the one granted to the Laing, Wharton and Down Construction Syndicate (Limited) are, subject to the consent of the local authority and of the Board of Trade, to be taken over by the new Company, which will thus acquire the right of supply of the electric light over the entire area of the City of London. The capital of the Company is £800,000, divided into 40,000 preference shares and 40,000 ordinary shares of £10 each; and applications were invited for the ordinary shares by the Exploration Company (Limited) and the Electric and General Investment Company (Limited). Sir David Salamons, Bart., is the Chairman of the Company, and the Board of Directors include the Duke of Marlborough and three other Directors of the City of London Electric Lighting (Pioneer) Company (Limited). The chief engineer is Major-General C. E. Webber, C.B.; and the secretary is Mr. J. Cecil Bull, 1 and 2, Great Winchester-street, E.C. The list of subscriptions opened on Wednesday, closing yesterday (Thursday) for London, and at 11 a.m. to-day (Friday) for the country.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company notify that the coupons on their Five per Cent. Debentures, due August 1st next, will be paid on and after that date at the banking house of Messrs. Glyn Mills, Currie, and Co., 67, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

EASTERN EXTENSION TELEGRAPH COMPANY.—This Company announces the payment by warrant, on August 1st next, of the interest for the half-year ended July 1st instant, on their Four per Cent. Mortgage Debenture Stock. The transfer books will be closed from the 28th to the 31st July, both days inclusive.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company announces the payment by warrants, on August 1st next, of interest for the half-year ended July 31st on their Four per Cent. Mortgage Debentures. The transfer books will be closed from July 28th to August 1st, both days inclusive.

GLOBE TELEGRAPH AND TRUST COMPANY (LIMITED).—A balance dividend of 4s. 6d. per share is proposed by the Directors of this Company, a sum of £1,876 being carried forward.

NATIONAL TELEPHONE COMPANY (LIMITED).—The Stock Exchange Committee have ordered the further issue of 8,250 shares, Nos. 438,985 to 447,234, and £70,000 Four and a-Half per Cent. Debenture Stock, to be quoted in the Official List.

SERIES ELECTRIC TRACTION SYNDICATE, LIMITED (IN LIQUIDATION).—A meeting of the shareholders is to be held at the offices, 11, Queen Victoria-street, E.C., on August 12th, at 2 p.m., to receive an account of the winding up.

Digitized by Google

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended July 10, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,363.

CRICKET.—EASTERN TELEGRAPH COMPANY *v.* KENNETH ANDERSON AND Co.—The third annual match between these companies was played on Saturday last, at Morley's Ground, Neasden, when the Eastern team was victorious by an innings and three runs. Mr. Kenneth Anderson presented a bat for the highest individual score, and a ball for the best bowling average. The former was won by Mr. Burke, who played a steady innings of 37; and the latter by Mr. Couper, with an analysis showing six wickets for 23 runs. Mr. Richardson, for the Eastern Company, carried out his bat for 35, and Mr. Couper for 32. Major Granger made a good defence for his side with 15, against the bowling of Messrs. Couper and Chisholm and the excellent fielding of Messrs. Draper and Hardie. Mr. Jack did his best to retrieve the fortune of his side, and by vigorous hitting ran up 50 in a short time, but the result, as shown below, was an easy victory for the Eastern Company. Score:—

EASTERN TELEGRAPH COMPANY.—Chisholm, c Granger, jun., b Gurney, 0; Cole, b Jack, 0; Burke, st Sloper, b Gurney, 37; Hardie, b Jack, 4; Robertson, b Jack, 0; Couper (captain), b Hedderwick, 32; Richardson, not out, 35; Draper, h w, b Gurney, 0; Gardner, b Sloper, 3; Hensman, run out, 8; M'Millan, b Jack, 2; Payton, c A. Gardner, b Stuart Anderson, 0; extras, 3—total, 124.

MESSRS. KENNETH ANDERSON AND Co.—First Innings: A. Gardner, b Couper, 2; Sloper, c Cole b Chisholm, 11; Hedderwick, c Richardson b Chisholm, 0; G. C. Hawes, c Chisholm b Couper, 4; Kenneth Anderson, b Chisholm, 0; Jack (captain), b Couper, 3; Gurney, b Chisholm, 6; J. Gardner, c Chisholm b Couper, 0; Stuart Anderson, c Hardie b Couper, 4; C. Granger, c E. Gardner b Chisholm, 2; Major Granger, b Couper, 15; Strudurm, not out 1; extras, 0—total, 48. Second Innings: A. Gardner, c Burke b Chisholm, 1; Sloper, c Hensman b Chisholm, 4; Hedderwick, c Richardson b Chisholm, 0; G. C. Hawes, b Chisholm, 0; Kenneth Anderson, b Chisholm, 3; Jack, c McMillan b Couper, 50; Gurney, run out, 4; J. Gardner, c Draper b Chisholm, 0; Stuart Anderson, c Richardson b Hardie, 0; C. Granger, c Cole b Chisholm, 2; Major Granger, c Gardner b Chisholm, 0; Strudurm, not out, 2; extras, 7—total, 73.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 688.—Vol. XXVII. FRIDAY, JULY 24, 1891. Price Fourpence.

NOTES.

With the exception of the Chelsea Order of 1886, which was passed before the creation of the London County Council, all the Metropolitan Orders contain a clause giving the County Council power to appoint "competent and impartial persons to be electric inspectors for the purpose of inspecting electric lines and works and of certifying meters." On the strength of the Order of 1886, however, the Chelsea Vestry petitioned against the insertion of the above clause in the Cadogan Company's Order, and in spite of a very forcible plea for uniformity and economy in this matter from the representative of the County Council, Lord Basing's Committee decided that Chelsea required different treatment to the rest of the Metropolis. For ourselves we fail to see that a case was made out for departing from the uniformity of the "Model Order," and we cannot help thinking that the question was considered rather from the point of view of Vestry *v.* Council than from that of the public good.

This week has witnessed the laying of the foundation stones of two Polytechnic Institutes (one at Battersea, the other at Chelsea), and the opening of a Technical and Recreative Institute at New Cross. The former have been talked about for a considerable time past, and will have a distinctly educational purpose. The funds for the erection of the Battersea Institute have been provided by three large donations, but the endowment is quite inadequate, and it is hoped that some City Company will come forward to help. The New Cross Institute, on the other hand, has been built, fully equipped, and substantially endowed by the Goldsmiths' Company—the one City Company that for many years past has not only devoted large sums of money, but has given great care and forethought in founding numerous schools and other institutions, and whose excellent example has been followed by the Drapers. In addition to its educational classes, the Institute at New Cross provides a variety of recreation in the shape of concerts, athletics, cricket, tennis, and the like.

While the messenger service which has been provided by the Postmaster-General has so far fulfilled the expectations of the Department that it is proposed to extend it to the whole country after August 1st, a private company which, though not first to provide messengers, was foremost in establishing electric call boxes, has apparently met with some disappointment. The Boy Messengers Company were selected by the Postmaster-General for an attack which resulted in the excellent compromise of the licence which they had begged for all the time. The District Messenger Company had meanwhile been spreading their ingenious call boxes broadcast, and asked neither rental nor payment for fixing. We get very little for nothing now-a-days, and not much for sixpence, and the offer to place these electric calls on the premises of anyone who would have them seemed too good to be true; and since it is only quite recently that several houses in Kensington to which the wires have been laid for months have been provided with call boxes, we imagined that they could not keep pace with an immense demand. But during this week a circular has been sent round saying that, owing to the limited demand for the services of the messengers, the Company is reluctantly compelled to ask for a subscription of one guinea a year in advance, but that it was proposed to refund this sum if three guineas' worth of business was transacted in the course of the year. The recipients of the boxes—one cannot call them subscribers—naturally protested against the proposed charge, and we understand that the circular has been withdrawn, and the rental will not apply to boxes which have been asked for up to the date of the circular. The service of this Company, as well as that of the rival Company, is extremely useful, and, in several respects, is preferable to that of the Post Office, and we hope that they will extend their respective systems; but the jump from nothing to one guinea a year *in advance* is a considerable one, and its remission, after the three guineas' worth of business, is a rather complicated expedient. Meanwhile, we understand that the Boy Messengers Company continue to supply call boxes free of charge.

We are glad to learn that the Electric Construction Corporation are about to put into practice the system of guaranteeing or maintaining their accumulators, which has on several occasions been talked about. The opponents of secondary batteries have, with good reason, urged that the cost of up-keep of these expensive luxuries is an unknown quantity. Various widely differing estimates have been made as to the probable life of the plates under the best conditions, and the definition of these conditions remained as vague as the cost of which it is a factor. The Corporation have decided to advance on the principle of insurance, and hope, by taking a considerable number of batteries under their care, to make the good contribute towards the extra cost of the bad. At the same time, they propose to make different terms for maintenance, according to the arrangements which are made for charging, and the kind of work done on discharge. We understand that they propose to send an

Digitized by Google

expert to inspect the battery, the engine, and, probably, the attendant, and on the report to quote a price for the up-keep. For an important battery, such as at a central station, they hope to arrive at a charge of 8 per cent. per annum on the first cost. As a rule, the charge will be from 10 to 20 per cent. We understand that they are making arrangements for maintaining the accumulators at the Brighton station, and are in negotiation at Liverpool for tramway work. It will very greatly simplify the cost of electric traction if such a guarantee can be arranged, and if one penny per car mile will pay for the whole up-keep of the batteries, the working cost should be easily ascertained. For such work it is reasonable that the Corporation should desire, and, indeed, make it a condition, that the charging and the care of the cells in loading and unloading should be supervised by a man nominated by themselves. We hope that some such plan will be adopted by users of secondary batteries, for too often the plates are not renewed in time, and when once a battery gets into trouble the result is generally most unhappy. The careful inspection which is sure to take place if a contract for maintenance is made, should produce results tending to restore the confidence which has been much shaken of late.

THE extracts which we publish this week from Mr. TESLA'S lecture on alternating currents of very high frequency will be found instructive reading. The numerous experiments described are of great scientific interest, and in many cases suggest useful applications. The difficulties to be overcome before such currents can be utilised for engineering purposes are far too great to render their introduction on any large scale at all probable; but they may quite possibly be found advantageous for special purposes, such, for instance, as the production of ozone by means of the brush discharge. It is also possible that some of Mr. TESLA'S suggested developments with reference to illumination may in the future be profitably carried out, for the efficiency of the best known method of lighting is only a few per cent., and this may be increased in the manner described by Mr. TESLA, if a tolerably cheap converter can be found for transforming the alternating currents supplied to it into other currents of much greater frequency. Mr. TESLA'S condenser transformer appears to be an arrangement of this kind, and his experiments, as a whole, form the most practical realisation which has yet appeared of the idea of producing light as the direct result of alternating currents of great frequency. The experiments on the alteration of the character of the brush discharge as the frequency of the alternations was increased are very striking, and are likely to throw light upon the nature of flames. The great importance of displacement currents, and the diminished value of conduction currents, owing to impedance, when the alternations are very frequent, are also clearly brought out in many ways. It is this which explains one of the last experiments described, in which the carbon filament of a glow lamp remains quite dark while the rarefied gas surrounding it is brilliantly illuminated; and the fact that the electric glow is equally intense at the surface, both of sharp points and round knobs, can only be accounted for by assuming that the phenomenon is mainly attributable to condenser action.

MR. TESLA contends that his effects are chiefly electrostatic, but, as Prof. J. J. THOMSON very pertinently remarks in our correspondence columns this week, "it is advisable to have a clear idea of what we mean by electrostatic action" in connection with this subject. The word has, until lately, been confined to phenomena caused by steady electric stresses, and rapidly alternating electromotive forces, such as Mr. TESLA has been dealing with, should not be so referred to. When currents are alternating with great rapidity the electric and magnetic phenomena are so intimately connected that it is next to impossible to separate them, and from a theoretical point of view it is undesirable. In fact the two sets of phenomena cannot exist apart, and Mr. TESLA'S effects are "electrostatic" simply because he has only used apparatus which indicates the presence of alternating electromotive forces.

British Association.—We hear that Prof. Silvanus Thompson will lecture, during the Cardiff meeting, to the operative classes, on Electricity in Mining.

Notices of Application for Provisional Orders:—Paddington—Paddington and Bayswater Electric Light and Power Supply; London Electric Lighting Company.

University College, Bristol (Chemical Department).—The Session 1891-92 of this College begins on 8th October. Further particulars will be found in our advertisement columns.

Kingswood.—At the last meeting of the Local Board the question of the electric light came forward for final decision, and it was decided to accept the tender of Messrs. Parfitt, of Keynsham.

Hove.—The Hove Commissioners have adopted the report of the Electric Lighting Committee, which recommends the installation, under Mr. R. E. Crompton's advice, of the three-wire system with storage.

Huddersfield.—At the last meeting of the County Council, it was decided to accept the amended tender of the Brush Electrical Engineering Company for the installation of the electric light, at a cost of £20,640.

Brighton.—Notice has been received from the Brighton and Hove Electric Light Company of their intention to apply for a Provisional Order to authorise them to supply electricity for public and private purposes within the area of the Urban Sanitary District of Brighton.

St. Moritzbad.—The central station for lighting the three large hotels at St. Moritzbad, in the Engadine, started work on the 23rd ult. Power is derived from the Julierbach at Silvaplana, about three miles distant. A fall of about 600 feet is used to drive turbines which are coupled direct to three 160 H.P. Ganz alternators. The transmission is effected at a pressure of 3,000 volts, the line being run on oil insulators.

Electric Traction in Paris.—Our Paris correspondent writes us that a Committee of the Municipal Council has decided in favour of the construction of a subterranean electric tubular tramway from the Bois de Boulogne to the Bois de Vincennes, passing under the Boulevard Diderot, the Rue de Rivoli, the Place de la Concorde, and the Avenue des Champs Elysées. This decision is, however, he says, without much meaning.

Direct Spanish Telegraph Company.—A branch station of the Direct Spanish Telegraph Company, in direct communication with their cable system, was opened on the 20th inst. at the general offices of the Company, 280, Winchester House, Old Broad-street, where telegrams for Spain and the Canary Islands, Portugal and Gibraltar, the West Coast of Africa, South America, &c., can be handed in from 10 a.m. to 6 p.m.

Munich.—The following are some additional particulars relating to the municipal electric lighting scheme at Munich, to which we referred in our issue of May 8th. The river Isar is to supply the necessary motive power, viz., 2,200 H.P. Some 5¾ miles of streets will be lighted by 307 arcs, and the public and municipal buildings will absorb nearly 6,000 16 c.p. glow lamps. It is proposed to charge 1¾d. per 16 c.p. lamp per

Digitized by Google

hour (about 2s. 6d. per B. T. unit), and 1s. 5½d. per arc lamp per hour.

Royal Alfred Aged Merchant Seamen's Institution.—The following resolution was unanimously passed by the Committee of this Institution on the 8th inst.:—"That, in consideration of the kind interest and powerful aid extended to this Institution by Sir James Anderson, a ward at the home at Belvedere be named 'The Submarine Telegraph Ward,' and that Sir James Anderson be requested to allow his name to be placed on the list of Vice-Presidents of the Royal Alfred Aged Merchant Seamen's Institution."

Telephone Cables in the City.—At the last meeting of the Commissioners of Sewers, Mr. Sayer presented a report of the Streets Committee relative to an application by the National Telephone Company to place a portion of their telephone cables beneath the public ways, the Committee stating that, in their opinion, it was inexpedient to give consent to the application of the Company to use the subsoil of the City until the contracts lately entered into for electric lighting purposes have been carried out. The recommendation was agreed to without discussion.

The Tudor and Correns Secondary Batteries.—A meeting was recently held at the Central Hall, Hamburg, at the invitation of the Berlin Electric Lighting Company, of about 40 persons interested in the electrical industry, amongst whom were representatives of the firms Schwarz, Kopf, and Co., the Allgemeine Elektricitäts Gesellschaft, Siemens and Halske, Müller and Einbeck; Professors Voller, Pinkert, and Kohlrausch. A Committee was appointed to carry out investigations as to the merits of the Tudor and Correns secondary batteries.

Funeral of Mr. Willoughby Smith.—The funeral of Mr. Willoughby Smith took place, on Wednesday, at Highgate Cemetery. The Institution of Electrical Engineers was represented by Prof. Crookes, Prof. Carey Foster, and Mr. F. H. Webb. Amongst those present were Captain Halpin, Messrs. E. Dickens, Clifford, T. Brown, Stevenson, and nearly 100 of the Telegraph Construction and Maintenance Company's Greenwich and Wharf-road staffs; Mr. Saunders, representing the Eastern Telegraph Company; Mr. Robert France, and many other friends of the deceased.

A Useful Formula.—The following is a simple formula for determining the insulation resistance between a dynamo circuit and its frame:—

$$R = \frac{E - \epsilon}{\epsilon} \times r,$$

where R = insulation resistance in ohms, E = the terminal E.M.F. of the machine, ϵ = the sum of the volts observed between the positive brush and the frame, and between the negative brush and the frame, and r = the resistance of the voltmeter, which must be very high.

Transmission of Power at Oyonnax.—A large and interesting transmission of power plant has been in successful operation at Oyonnax, in the east of France, since March, 1890. Power is obtained from a 1,750 H.-P. fall, five miles from the town, where two 105 kilowatt 2,000 volt Thury machines are coupled direct to two horizontal turbines. The current is transmitted on the three-wire system to two 120 H.-P. 1,800 volt motors, driving direct on to two 125 volt 600 ampere dynamos, which supply current to the town on the three-wire system. The commercial efficiency of this arrangement is said to be 76·2 per cent.

Thunderstorms.—Severe thunderstorms continue to occur in various parts of the United Kingdom. At the end of last week, Newcastle and the Hartlepools experienced a succession of storms. On Sunday, Leeds and Middlesborough were visited. On Tuesday, a heavy thunderstorm passed over Norwich. The centre of the disturbance lay over the northern side of the city, and, when at its height, the lightning struck the tower of St. Michael Coslany Church, dislodging the ball surmounting the vane and tearing into splinters the crocketed standard supporting it. As far as could be ascertained, the fabric of the tower was undamaged.

Magnetic Anomalies.—In a recent issue of *Nature*, M. Alfonso Sella, of Biella, referring to the discovery of very strong magnetic anomalies between Charkov and Kursk, in Russia, by General A. de Tillo (*The Electrician*, Vol. XXVI., p. 689), raises the question whether the values there observed are strictly local, or extend over a relatively wide area. It would, he says, be of great interest to know if, on moving, say, some metres away from a station, the declination and inclination hold the same value. If not, there is clearly some cause which acts at a short distance; but if constancy is observed a great step would be taken towards the settlement of the question as to the existence of strong variations common to a wide area.

The London Telephone Service.—A deputation, consisting of Colonel Raynsford Jackson and Captain Davies, attended at the London Chamber of Commerce, on Tuesday. They came for the purpose of requesting the Chamber to appoint a Committee to inquire into the whole question of the position of the telephone companies in regard to rates, efficiency of service, and statutory powers, with the view of assisting the companies to supply the public with a more efficient service. Representatives of the Telephone Association of London were also in attendance, and as these gentlemen acquiesced in the proposal for the appointment of a Committee it was determined that the Committee should be formed.

A Long Electric Line.—The Thomson-Houston Electric Company has just entered into a contract for the equipment of the San Francisco and San Mateo Electric Railway. The plant will at first consist of six 80 kilowatt generators and 30 cars, 15 of which are to carry two 15 H.P. motors, while the remaining 15 cars are to carry a 25 H.P. motor. It is anticipated that the first section of the line will be completed in October. This contract means that the Thomson-Houston Company will equip what is, perhaps, the nearest approach to a regular electric railway in America. The San Francisco and San Mateo Company has already obtained a concession for its line from San Francisco through the suburban towns of San Bruno, Millbrae, Ocean View, San Mateo, and Belmont, to Redwood City, a distance of 28 miles. An application has been made for an extension through the counties of San Mateo and Santa Clara to San Jose, a distance of about 52 miles from the city.

Electricity for Nurses.—The summer term at Grafton College, Fitzroy-square, has just concluded with an examination conducted by J. Russell Harris, M.D., W. E. Sumpner, D.Sc., Arthur Harries, M.D., and H. Newman Lawrence, M.I.E.E., and certificates have been awarded. One student, an M.D., has obtained high honours in electricity and electro-therapeutics, while another has passed in the second division "with credit." The Papers set and the practical examination together form a satisfactory test of the knowledge on anatomy, physiology, electricity, electro-therapeutics, and masso-therapeutics necessary for the intelligent performance of medical men's instructions in the treatment of disease by electricity and massage. Nurses so trained will not be likely to perpetrate the absurd and often dangerous mistakes made by many who profess ability to administer electricity or "apply the battery" as they say, and we think medical men cannot fail to appreciate the advantage of having ready to their hand nurses who know something about electrical applications to the body, and why and how they are performed.

The Chicago Exhibition.—The delegates to the chief Continental cities from the executive of the Chicago Exhibition were received on Monday at a special meeting of the Council of the Society of Arts, convened in their new capacity as a Royal Commission for the management of the British section of the Exhibition. The Attorney-General, as chairman of the Council, presided, and a large number of the members were present. The Hon. Benjamin Butterworth, the head of the delegation, in replying to the Attorney-General's speech of welcome to him and to his colleagues, gave an exceedingly satisfactory account of the state of the preparations, and said, among other things, that the inhabitants of Chicago had now provided funds to the extent of $12,000,000, and that they were determined to spare no pains to render the Exhibition a success.—At a Council meeting of the London Chamber of Commerce, on Tuesday, Sir Philip Cunliffe Owen introduced the deputation from the Chicago Exhibition. The chairman, Sir A. Rollit, promised that every assistance in the way of publicity should be given; and he agreed that British manufacturers should take the lead and hold the premier position at Chicago.

Lead Covering for Cables.—We may conclude (says Mr. L. D. Bishop, in the *Electrical Engineer* of New York) that, under ordinary conditions, lead is practically a perfect, if not an everlasting, cable protector. It is no argument to say that lead will fail under conditions such as those of special and extra-ordinary chemical action, which would destroy any metal; but even there lead will hold its own, for the salts formed on the surface generally make a crust which prevents further action beneath it. The writer has handled lead pipes which were laid down in Pompeii more than 1,800 years ago. Some six years ago they were in use for conveying water, to all intents as good and sound as when laid. It may be objected that no parallel can fairly be drawn between lead pipes which have laid under ashes and scoria for 18 centuries, and those laid in our great modern cities, in conduits exposed to destroying gases and corroding effluvia, But it is a very fair comparison. Those pipes were laid underground long before Pompeii was buried, and, judging from appearances, the inference is unavoidable that dirt and filth flourished there in much greater luxuriance than even in that queen of dirty metropolises, New York.

The Photogenic Efficiency of Various Sources of Light.—In a recent communication to the Académie des Sciences, M. Witz gives the following figures relating to the comparative photogenic efficiency of various sources of light:—

Sources of Light.	Expenditure.	Calories transformed.	Intensity in carcels.	Calories per carcel-hour.
Stearine candle	10·5 grammes per hour...	110	$\frac{1}{6·5}$	716
Ordinary gas-burner	105 litres per hour.....	567	1	567
Regenerative lamp	35 litres per hour.....	189	1	189
Glow lamp	3·5 watts per candle.....	3·1	$\frac{1}{6·5}$	20
Arc lamp	4·5 watts per carcel	4	1	4

If we take the arc lamp as our standard the comparative efficiencies are as follows:—Arc lamp, 100; glow lamp, 20; regenerative gas-burner, 2·1; ordinary gas-burner, ·7; stearine candle, ·56.

Electric Lighting by Water Power.—The Pacific Wenstrom Electric Company recently installed an electric lighting plant at the Geysers Hotel in Sonoma County, California, which possesses, says the *Electrical World* of New York, some points of interest. A 24-inch Dodd water wheel was used under a head of 158 feet with a one-inch nozzle, no governor being used. The plant is located near the bottom of a deep ravine about 100 yards from the hotel. The curve of efficiency of the water wheel was used as a guide for over-compounding the dynamo, and the results obtained are somewhat remarkable. When the water gate was wide open readings were taken, which showed the following results: 60 lights, 750 revolutions, voltage at dynamo, 111; 30 lights, 910 revolutions, voltage at dynamo, 108; 1 light, 1,060 revolutions, voltage at dynamo, 106. The voltage at the hotel was practically constant. When the brushes were removed from the commutator the speed of the dynamo ran up to about 1,200. In the operation of the plant the water is turned on at about six o'clock, and the oil cups filled, and no further attention is given to the plant until it is shut down at about one o'clock, after seven hours' continuous running. The normal speed of the dynamo was 950 revolutions, but over-compounding brought the full load speed down to 750. The reason of the high efficiency of this type of wheel is said to be due to the shape of the buckets. The feature of the new bucket consists in curving the corners of the bucket down, so as to partly surround the nozzle. The effect is that the water is discharged below the line of impact. With other wheels, the water is discharged upwards toward the axis of the wheel, and interferes with the succeeding buckets.

The Insolubility of Pure Metals in Acids.—The results of an investigation concerning the cause of the insolubility of pure metals in acids are contributed by Dr. Weeren to the current number of the *Berichte*. De la Rive, so long ago as the year 1830, pointed out that chemically pure zinc is almost perfectly insoluble in dilute sulphuric acid. Dr. Weeren's theory of the phenomenon is as follows: "Chemically pure zinc and also many other metals in a state of purity are insoluble or only very slightly soluble in acids, because, at the moment of their introduction into the acid, they become surrounded by an atmosphere of condensed hydrogen, which under normal circumstances effectually protects the metal from further attack on the part of the acid." The experiments from which this theory has been derived were briefly as follows. The amount of chemically pure zinc dissolved by the acid was first determined. It was next sought to determine what difference would be effected by performing the experiment *in vacuo*, when of course the escape of the hydrogen would be greatly facilitated. The solubility was found under these circumstances to be increased sevenfold. Next the experiment was performed at the boiling temperature of the dilute acid, first when ebullition was prevented by increasing the pressure, and secondly when ebullition was unhindered. In the first case, when ebullition was prevented, the solubility was practically the same as in the cold; while in the second case, with uninterrupted ebullition, the solubility was increased 24 times. Finally, experiments were made to ascertain the effect of introducing into the acid a small quantity of an oxidising agent capable of converting the hydrogen film to water. When a little chromic acid was thus introduced the solubility was increased 175 times, and when hydrogen peroxide was employed the solubility was increased three-hundred-fold. The explanation of the ease with which the metal becomes attacked when the ordinary impurities are present is that the hydrogen is not then liberated upon the surface of the zinc, but rather upon the more electro-negative impurities, leaving the pure zinc itself open to the continued attack of the acid.

The Goolden-Atkinson Separator.—Amongst the machines shown at the recent meeting of the Royal Agricultural Society, at Doncaster was a magnetic separator, intended to remove bolts, nuts, nails, horse-shoes, &c., from bones, oilcake, or minerals, before they are passed into disintegrating machines. The chief difficulties that had to be overcome in designing this machine were the large size and irregular shapes of the material to be treated, the fact also that the iron—particularly in bones—is frequently entangled in the bones, so that merely passing the substance *once* over or on to a magnet was not found sufficient to ensure the absolutely certain removal of the foreign substance. These points have been satisfactorily overcome by the use of a hollow truncated cone with 10 internal magnets of alternately opposite polarity. The cone revolves on outside runners, driven by friction only, which is found ample for the purpose. The bones are fed into the back end by a shoot, and, falling to the bottom, are rolled over and over again, so that, as they gradually travel forward—in about 10 or 15 complete revolutions—to the front, they pass 100 to 150 times over the magnets. In the upper part of the barrel is a fixed tray, into which the iron is carried and collected. Each magnet in turn, as it comes to the bottom, is magnetised, and remains so till it reaches the top, where it becomes demagnetised, and the iron is detached. This process is carried out by a commutating ring on the back of the machine, and the arrangement is such that each coil has one end permanently connected to one pole of the dynamo, and the other ends are in turn connected during one-half a revolution to the other pole. Thus the magnets receive current in parallel. Before cutting a coil out of circuit it is short-circuited through a resistance, and by this means no sparking of any consequence occurs. The machine has proved itself a very practical success, and the value of the repeated revolutions over the magnets has been demonstrated by many trials. The power required to excite the magnets is about 600 watts for the largest size, capable of dealing with four tons of bones per hour. The machine was exhibited by the Hardy Patent Pick Company, of Sheffield, and was manufactured by Messrs. W. T. Goolden and Co., under the joint patent of Messrs. L. and C. Atkinson and G. W. Elliott.

MAGNETISM IN IRON AND OTHER METALS.*—XLV.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 267.*)

§ 156. **Ring Magnet with an Air Gap.**—We shall next consider a magnetic circuit consisting of a uniform iron ring, in which a narrow radial crevasse has been cut. When the ring is magnetised there is some leakage of lines of induction through it sides into surrounding space, especially near the crevasse, but most of the lines jump directly across the crevasse. We may conceive the magnetic circuit of the ring to be completed—though not quite perfectly—by a plate of air filling the crevasse, of the same area of cross section as the ring itself. The lines of induction spread somewhat in crossing the crevasse, and a closer approximation to the condition of a perfect circuit would, therefore, be reached by supposing the plate of air to have an area of cross section rather larger than the cross section of ring, the extent of this enlargement being dependent on the thickness of the crevasse. In the case which we postulate, however, the crevasse is very narrow, and it will suffice to take its area of section as no more than equal to that of the ring. Let s be the area of section, l the mean length of the complete ring (before the crevasse is cut), and δl the (small) mean thickness of the crevasse. Let the ring be magnetised, as before, by a coil of N turns, carrying a current C. The permeability of the ring is μ, and that of the gap is unity. Then,

$$\text{Flux} = \frac{\text{magnetomotive force}}{\text{magnetic resistance}} = \frac{4\pi C N}{\frac{l-\delta l}{\mu s} + \frac{\delta l}{s}} = \frac{4\pi C N \mu s}{l + \delta l (\mu - 1)}.$$

If there had been no gap, the flux would have been $\frac{4\pi C N \mu s}{l}$.

The effect of removing a short length, δl, of the iron, and substituting air as the material through which the magnetic circuit is completed, is to increase the resistance of the circuit as much as it would be increased by the addition of a length of iron equal to $\delta l (\mu - 1)$.

§ 157. **Comparison of a Split-Ring with an Ellipsoid.**—It is interesting to compare the case of a ring in which there is a gap with that of an ellipsoid of finite length.† In the ellipsoid, as we have already seen (§ 26), the free magnetism produces a self-demagnetising force, which is proportional to the amount of magnetisation, and opposes the action of the magnetising coil. If we call H the true magnetising force acting on the metal, and H' that part of the magnetising force which is due to the action of the coil alone, then

$$\mathsf{H} = \mathsf{H}' - \mathsf{N}\,\mathsf{I},$$

where I is the intensity of magnetisation, and N is a numerical factor, the value of which depends on the relation of the length of the ellipsoid to its transverse dimensions. We shall see that a precisely similar formula may be obtained for the ring with a gap by treating it as a nearly perfect magnetic circuit.

Since the magnetisation of the cut ring is very nearly uniform, the actual magnetic force in the iron, which is the resultant of that due to the coil and that due to the free magnetism, must also be very nearly uniform. Call this force H, and call H' the magnetising force due to the coil alone, which (on the supposition that the coil is uniformly wound) is $\frac{4\pi C N}{l}$.

Then $$\mathsf{H} = \frac{\mathsf{B}}{\mu} = \frac{\text{Flux}}{\mu s} = \frac{4\pi C N \mu s}{\{l + \delta l (\mu - 1)\}\mu s} = \frac{4\pi C N}{l + \delta l (\mu - 1)};$$

and $$\mathsf{H}' = \frac{4\pi C N}{l}.$$

Therefore, $\mathsf{H}' l = \mathsf{H}\{l + \delta l (\mu - 1)\}$,

$$\mathsf{H}' = \mathsf{H}\left\{1 + \frac{\delta l}{l}(\mu - 1)\right\},$$

$$= \mathsf{H}\left(1 + \frac{4\pi\kappa\,\delta l}{l}\right),$$

since $\mu = 4\pi\kappa + 1$.

Hence, $$\mathsf{H}' = \mathsf{H} + \frac{4\pi\delta l}{l}\mathsf{I},$$

or, $$\mathsf{H} = \mathsf{H}' - \frac{4\pi\delta l}{l}\mathsf{I}.$$

The factor $\frac{4\pi\delta l}{l}$ therefore take the place of the factor N in the formula for ellipsoids. Its magnitude depends on the proportion of the width of the crevasse to the whole length of the circuit.

Taking the case of a circular ring, this proportion may be expressed by reference to the angular aperture of the crevasse, that is to say, the angle subtended by the crevasse at the centre. Calling this angle α in degrees, $\frac{\delta l}{l} = \frac{\alpha}{360}$ and $\mathsf{N} = \frac{4\pi\alpha}{360}$.

The following table has been calculated by Du Bois, to show what aperture of crevasse in a circular ring produces the same self-demagnetising force as exists in ellipsoids of certain stated elongations :—

Ratio of Length to Diameter of Ellipsoid.	Factor N.	Equivalent Aperture in Circular Ring (degrees).
20	0·0848	2·41
30	0·0432	1·22
40	0·0266	0·76
50	0·0181	0·52
100	0·0054	0·15

It is scarcely necessary to add that the self-demagnetising force which is introduced by the presence of the crevasse affects the residual magnetism of the ring as well as the induced magnetism, precisely as it does in the ellipsoid. When the magnetising-circuit of the split-ring is broken, the residual magnetism causes a reversed force to act on the metal, the value of which is $\frac{4\pi\delta l}{l}\mathsf{I}_r$, where I_r is the residual intensity of magnetism. This prevents the residual magnetism from being nearly so great as it would be were the ring complete—indeed, a very narrow crevasse is sufficient almost wholly to destroy the (otherwise very great) residual magnetism of a soft iron ring. For example, in a ring of soft annealed iron, which, when uncut, retains, after being strongly magnetised, a residual induction, B_r, of 12,000 units, the presence of a gap only half a degree wide will reduce the residual value of the induction to about 1,000.

§ 158. **Graphic Representation of the Influence of a Narrow Gap.**—The influence of a narrow gap, both in resisting magnetisation and in promoting demagnetisation, is best seen by resorting to the graphic construction which has been already explained in relation to ellipsoids and long rods (§ 48). Let a, a, a (Fig. 132) be curves of magnetisation (curves of I and H) for the iron of the ring. Find the factor N, equal to $\frac{4\pi\delta l}{l}$, and draw the line O A, so that A M (drawn parallel to the axis along which H is measured) shall be to O M as $\frac{4\pi\delta l}{l}$ is to I. Then the intercepts between O M and O A represent the values of the self-demagnetising force, due to the corresponding values of I, and if we wish to represent the relation of the magnetism to the magnetising force produced by the coil alone (the force which has been called H' above), we have only to draw a diagram in which the lines a, a, a are sheared into the position b, b, b by taking the abscissas from O A instead of from O M, or, in other words, by adding $\frac{4\pi\delta l}{l}$ to H in every case. Thus, any point P′ in the new curve is found from the corresponding point P by taking P′R = PR + QR. The residual magnetism, which was O S in the ring without a gap, is reduced to O S′ in the ring with a gap. If the object of the construction had merely been to find the residual magnetism, O S′, that could have been done more readily by drawing O T inclined at the same angle as O A, but on the other side of the axis of I, to meet the descending curve a, and projecting S′ from the point of

* All rights are reserved.

† See a Paper by H. E. J. G. Du Bois, *Phil. Mag.*, Vol. XXX., 1890, p. 335.

Digitized by Google

intersection of O T with the curve. The same construction will, of course, serve to find the residual magnetism of ellipsoids, or of long rods, which may be treated as approximating to ellipsoids.*

In Fig. 132 we have supposed that the magnetisation of the iron is exhibited by means of a curve of I and H. If, instead of this, the curve of B and H were given, a similar graphic construction would still serve to show the effect of the gap. Since $\mathsf{I} = \frac{\mathsf{B}-\mathsf{H}}{4\pi}$, the self demagnetising force $\mathsf{N}\,\mathsf{I} = \mathsf{N}\frac{(\mathsf{B}-\mathsf{H})}{4\pi}$, which, in a very permeable substance like iron, is practically equal to $\frac{\mathsf{N}\,\mathsf{B}}{4\pi}$, since B is very great compared with H. Substituting for N its value $\frac{4\pi\,\delta\,l}{l}$, this becomes $\frac{\mathsf{B}\,\delta\,l}{l}$. The line O A has, therefore, to be drawn, in a diagram of B and H, at such an inclination that when O M represents B, M A is $\frac{\mathsf{B}\,\delta\,l}{l}$.

From the equation $\mathsf{H} = \mathsf{H}' - \mathsf{N}\,\mathsf{I}$, by substituting $\frac{\mathsf{B}-\mathsf{H}}{4\pi}$ for I,

we have $$\mathsf{H} = \mathsf{H}' - \frac{\delta\,l}{l}(\mathsf{B}-\mathsf{H}),$$

or $$\mathsf{H}'\,l = \mathsf{H}(l-\delta\,l) + \mathsf{B}\,\delta\,l.$$

$\mathsf{H}'\,l$ is $4\pi\,\mathrm{C\,N}$; it is the line integral of the magnetic force taken round the whole circuit, or, in other words, the magnetomotive

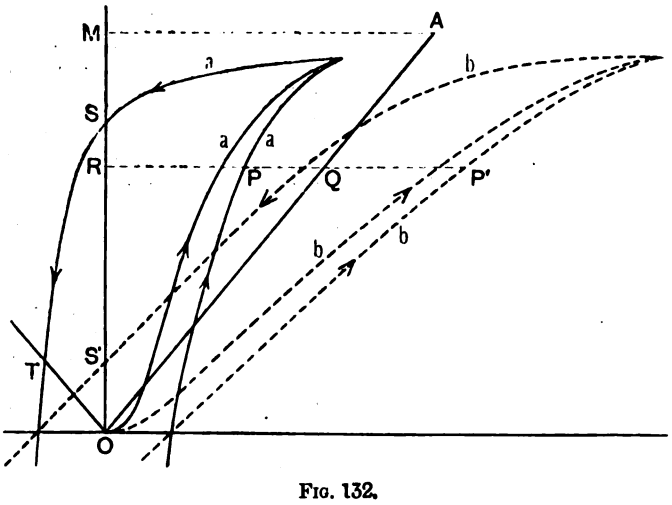

Fig. 132.

force. H is the magnetic force in the iron, and $\mathsf{H}(l-\delta\,l)$ is that part of the line integral which is taken through metal. B is equal to the magnetic force in the gap, and therefore $\mathsf{B}\,\delta\,l$ is that part of the line integral that is taken through air. The equation might evidently have been written down directly; it expresses the simple fact that the line integral for the complete circuit is made up of two parts, in one of which—namely, the iron, whose length is $l-\delta\,l$—the magnetic force has the sensibly uniform value H, while in the other—namely, the one whose length is $\delta\,l$—the magnetic force has the sensibly uniform value B. We have derived it otherwise, in order to accustom the student to observe the connection between the treatment of the ring as a magnetic circuit and that other treatment which deals with the magnetic condition at individual points. In the language of the magnetic circuit, $\mathsf{H}(l-\delta\,l)$ represents that part of the whole magnetomotive force which is used up in overcoming the magnetic resistance of the iron, and $\mathsf{B}\,\delta\,l$ represents the remainder of the magnetomotive force, which is used up in overcoming the resistance of the gap. In soft iron, if the gap is of any considerable width, its resistance is so great compared with that of the ron that nearly the whole magnetomotive force is used in forcing the induction across the gap.

§ 159. **Graphic Representation of the Relation of Flux to Magnetomotive Force.**—In dealing with the magnetic circuit as a whole, it is convenient to modify and generalise the graphic construction exemplified in Fig. 132, by drawing the abscissas to represent the whole magnetomotive force, and the ordinates to represent the whole magnetic flux in the manner first described by J. and E. Hopkinson.* Such a curve may obviously be derived for any part of a magnetic circuit from the curve of induction and magnetic force for the material by multiplying the induction by the area of section s to find the whole flux, and by multiplying the magnetic force by the length of the piece to find the magnetomotive force required for the magnetisation of that part of the circuit. Then, by graphically summing the abscissas for successive parts of any composite magnetic circuit, the whole magnetomotive force is represented in relation to the flux. An example will make the method intelligible. Take, as before, the case of an iron ring of uniform section with a gap in it, the length of the gap being $\delta\,l$, and that of the iron $l-\delta\,l$. From the curve of B and H for the metal of which the ring is formed—which we suppose to be known—draw the curve O P (Fig. 133), for the iron, in which any ordinate, P p, is the flux, B s, and the corresponding abscissa, O p, is $\mathsf{H}(l-\delta\,l)$. Next draw the curve O Q for the gap, in which the ordinate Q q is again B s, and the corresponding abscissa O q is the magnetomotive force required *for that part of the circuit*, namely $\mathsf{B}\,\delta\,l$. The line O Q is evidently straight, as it relates to a non-magnetic substance in which induction is proportional to magnetic force. Then draw the resultant curve O R, in which for each ordinate the abscissa is the sum of the abscissas of the curves already

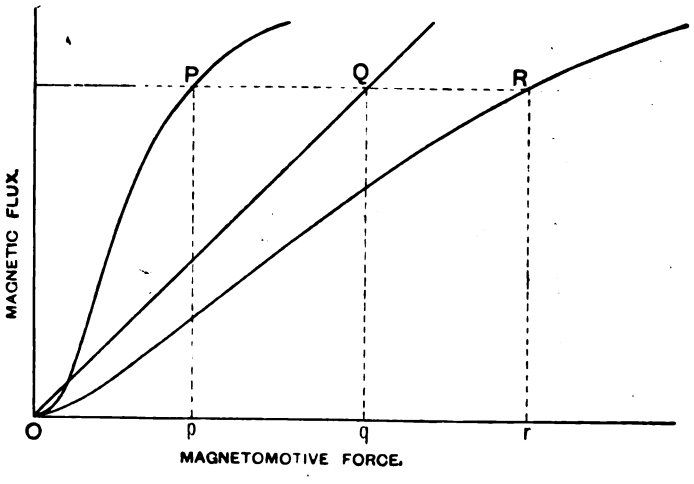

Fig. 133.

drawn, namely, O r = O p + O q. O r is the magnetomotive force required for iron and gap together, and the curve O R shows the relation of the flux to the magnetomotive force in the circuit as a whole.

Moreover, the construction may be applied with equal facility to the descending limb of the curve, or to exhibit the behaviour of the circuit in any cycle of magnetisation. In the line O R the descending and ascending limbs coincide; in the iron part of the circuit the ascending and descending limbs have to be drawn separately, and the process of summing the abscissas has to be applied successively to each (as in Fig. 132) in order to determine a curve which will show the effects of hysteresis in the magnetic circuit as a whole, and all the variations of magnetic flux under cyclic variations of magnetomotive force.

Again, the method may evidently be extended to magnetic circuits of a more complicated form, containing, let us say, successive pieces of different material, of lengths l_1, l_2, l_3, &c., and section s_1, s_2, s_3, &c. We must know, to begin with, the curve of B and H for each material. From these curves draw a set of curves of which the ordinates are respectively $\mathsf{B}\,s_1$, $\mathsf{B}\,s_2$, $\mathsf{B}\,s_3$, &c., and the abscissas are $\mathsf{H}_1\,l_1$, $\mathsf{H}_2\,l_2$, $\mathsf{H}_3\,l_3$, &c. The required curve of flux and magnetomotive force for the whole circuit will be found by compounding these curves; that is to say, by drawing a curve in which, for a given ordinate, the abscissa is the sum of the abscissas of the separate curves

* This construction, for finding the residual magnetism of ellipsoids, is given by J. Hopkinson, *Phil. Trans.*, 1885, p. 465.

* *Phil. Trans.*, 1886, Part I., p. 331.

Digitized by Google

The complete curve exhibiting what happens when the complex circuit is carried through a cyclic process of magnetisation may be found in this way, provided the cyclic curves for each of the materials are determined beforehand.

§ 160. **Application to Dynamos.**—A principal use of this method is to determine the magnetomotive force, and consequently the number of ampere-turns, required to produce a stated magnetisation in a circuit made up of pieces the dimensions and magnetic qualities of which are known. The method was, in fact, invented by J. and E. Hopkinson as a means of solving practical problems in the design of a dynamo, where the magnetic circuit is made up of (1) the cores of the field magnets, (2) the yoke, (3) the pole pieces, (4) the core of the armature, and (5) the non-magnetic spaces on either side of the armature, between it and the pole pieces. This last is much the most important item in the resistance of the circuit. The magnetic circuit of a dynamo is far from perfect, and the estimation of the effective length and effective cross section of each part is subject to some uncertainty, so that the results are no more than rather roughly approximate. To pursue the application in detail would be beside our present purpose: the student should in any case refer to the original Paper.* One point, however, must be briefly mentioned, being of general interest in relation to other magnetic circuits as well as to the circuit of the dynamo.

In the dynamo circuit the flux is by no means uniform throughout; there is much leakage. The flux is greatest in the magnet limbs, which are the seat of the magnetomotive force, and in the armature it is considerably less. Its value in the armature is, however, the matter of chief interest in the practical problem. Calling F_1 the value of the flux in the armature, the fluxes F_2, F_3, &c., in other parts of the circuit may be expressed by the use of factors q_2, q_3, &c., such that $F_2 = q_2 F_1$, $F_3 = q_3 F_1$, and so on. These factors are sometimes called coefficients of leakage; in the case considered they are greater than unit. They may be found experimentally by comparing the forces ballistically by means of induction coils wound at different places in the circuit, or by measuring directly the number of stray lines of induction in the air round about the several portions. They are not strictly constant, but tend to increase when the flux approaches saturation. When they are known, we may obtain a better approximation to the true equation of the magnetic circuit by writing

$$4\pi C N = \frac{l_1 F_1}{\mu_1 s_1} + \frac{l_2 F_2}{\mu_2 s_2} + \frac{l_3 F_3}{\mu_3 s_3} + \&c.,$$

or

$$\left(4\pi C N = F_1 \frac{l_1}{\mu_1 s_1} + \frac{q_2 l_2}{\mu_2 s_2} + \frac{q_3 l_3}{\mu_3 s_3} + \&c.\right).$$

(To be continued.)

ON THE USE OF THE SILVER VOLTAMETER.

The following note on the use of the silver voltameter has been prepared by the Electrical Standards Committee of the Board of Trade:—

In the following specification the term "silver voltameter" means the arrangement of apparatus by means of which an electric current is passed through a solution of nitrate of silver in water. The silver voltameter measures the total electrical quantity which has passed during the time of the experiment, and by noting this time the time-average of the current, or if the current has been kept constant, the current itself can be deduced.

In employing the silver voltameter to measure currents of about 1 ampere the following arrangements should be adopted:—The cathode on which the silver is to be deposited should take the form of a platinum bowl not less than 10cm. in diameter, and from 4 to 5 cm. in depth.

The anode should be a plate of pure silver some 30 square cm. in area and two or three millimetres in thickness. This is supported horizontally in the liquid near the top of the solution by a platinum wire passed through holes in the plate at opposite corners. To prevent the disintegrated silver which is formed on the anode from falling on to the cathode, the anode should be wrapped round with pure filter paper, secured at the back with sealing-wax.

The liquid should consist of a neutral solution of pure silver nitrate, containing about 15 parts by weight of salt to 85 parts of water.

The resistance of the voltameter changes somewhat as the current passes. To prevent these changes having too great an effect on the current, some resistance besides that of the voltameter should be inserted in the circuit. The total metallic resistance of the circuit should not be less than 10 ohms.

Method of Making a Measurement.

The platinum bowl is washed with nitric acid and distilled water, dried by heat, and then left to cool in a desiccator. When thoroughly dry it is weighed carefully. It is nearly filled with the solution, and connected to the rest of the circuit by being placed on a clean copper support, to which a binding screw is attached. This copper support must be insulated. The anode is then immersed in the solution, so as to be well covered by it, and supported in that position; the connections to the rest of the circuit are made. Contact is made at the key noting the time of contact. The current is allowed to pass for not less than half-an-hour, and the time at which contact is broken is observed. Care must be taken that the clock used is keeping correct time during this interval.

The solution is now removed from the bowl and the deposit is washed with distilled water and left to soak for at least six hours. It is then rinsed successively with distilled water and absolute alcohol, and dried in a hot-air bath at a temperature of about 160°C. After cooling in a desiccator it is weighed again. The gain in weight gives the silver deposited.

To find the current in amperes this weight, expressed in grammes, must be divided by the number of seconds during which the current has been passed, and by ·001118. The result will be the time average of the current, if during the interval the current has varied.

In determining by this method the constant of an instrument, the current should be kept as nearly constant as possible, and the readings of the instrument taken at frequent observed intervals of time. These observations give a curve from which the reading corresponding to the mean current, time average of the current, can be found. The current, as calculated by the voltameter, corresponds to this reading.

THE SUB-TRANSFORMER SYSTEM OF LIGHTING AT CARLOW.

As briefly mentioned in our "Notes" last week, deputations from some of the principal local authorities of Ireland met at Carlow, on the 13th inst., to receive from Messrs. J. E. H. Gordon and Co., the contractors, particulars of their scheme for lighting the town by means of their "sub-transformer" system. A chief feature of the Carlow installation is the fact that power is derived from a water-wheel, erected at a distance of five miles from the town, in an unused mill on the River Barrow, a stream estimated to be capable of providing 200 H.P. so soon as the turbines, for which the necessary alterations are being made, are put down (*See* Fig. 1).

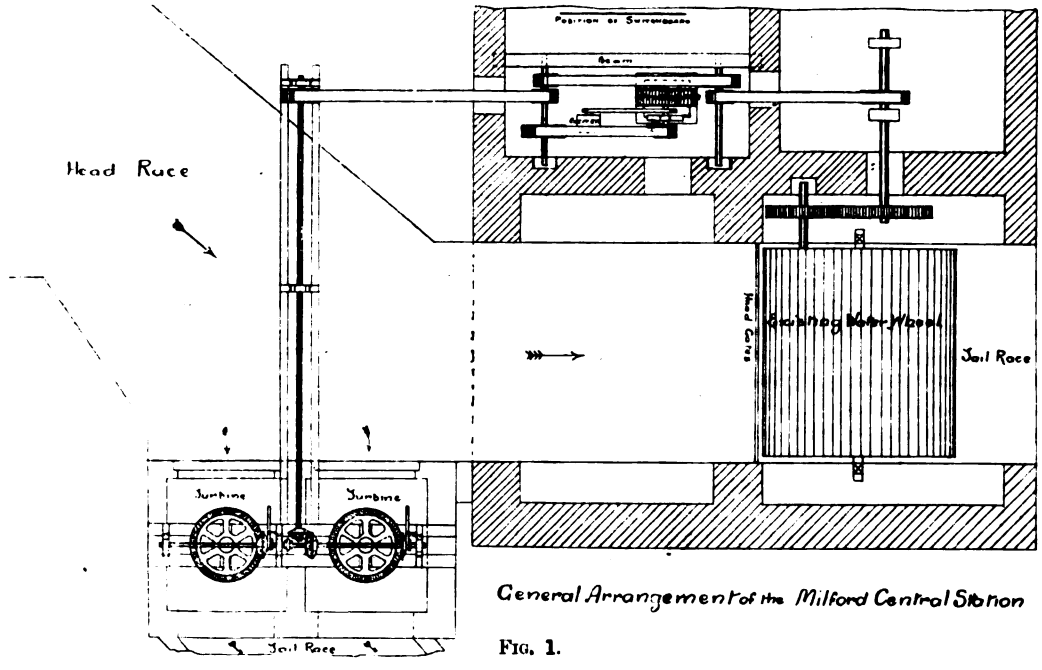
The water-wheel at present doing the work is 20ft. by 60ft. diameter, speed from 8 to 10 revolutions per minute, and this performs its duties very effectively, no hitch of any importance having yet occurred, although the light has been running for some time. There will eventually be two turbines installed (of Messrs. Carrick and Ritchie's make), and it is estimated that these will supply all the power necessary to light the five miles of straight but narrow streets of the town of Carlow, and the houses of its 6,000 inhabitants. As in most Irish towns, the proportion of large houses is small.

Messrs. Gordon have been fortunate in the selection of their field of operations, as the gas supply at Carlow was very bad, and some time ago the Town Commissioners had decided that oil

* See also a Paper by E. Hopkinson on the "General Theory of Dynamo Machines," Ref. Brit. Assoc., 1887, p. 614. Reference should also be made to Prof. S. P. Thompson's "Treatise on Dynamo-Electric Machines."

Digitized by Google

should be substituted for gas, the price of which, we understand, varied from 7s. 6d. to 5s. per 1,000 feet. The Commissioners, of whom Mr. Hammond, M.P., is the chairman, were favourably disposed towards the electric light, and accepted Messrs. Gordon's offer to light the town, granting them many facilities, such as the free use of the towing path of the Barrow for nearly five miles, for the erection of the posts for carrying the cables. Labour is cheap in the district, although the item for superintendence of the labourers must be a heavy one.



General Arrangement of the Milford Central Station

FIG. 1.

The first indication of the electric lighting is the appearance at irregular intervals of heavy posts, suspended from each of which is a Brockie-Pell arc lamp, taking eight amperes; and below the lamp about three feet, attached to the post, is a small transformer of the Gordon type. These posts are certainly not attractive, but the light is very steady, and the local press and public generally speak in terms of praise of the simplicity and effectiveness of all the arrangements.

FIG. 3.—Cable used for High-pressure Mains (7/16 insulated according to Board of Trade Rules).

A pamphlet issued by the contractors says that the "public lighting of the streets has hitherto been carried out by 100 oil lamps of 10 c.p. each, and costing the Town Commissioners £104 per year for a total light of 1,000 c.p. It is now carried out by 13 arc lamps of 1,200 c.p. each, and 40 incandescents of 16 c.p. each, giving a total light of 25,840 c.p., or 25 times the former amount; and for this the Commissioners pay £170 a year." As we understand that 8 amperes are used for the arcs, this current may, under the very best conditions, give 1,200 candles with a continuous current, at an angle of about 50

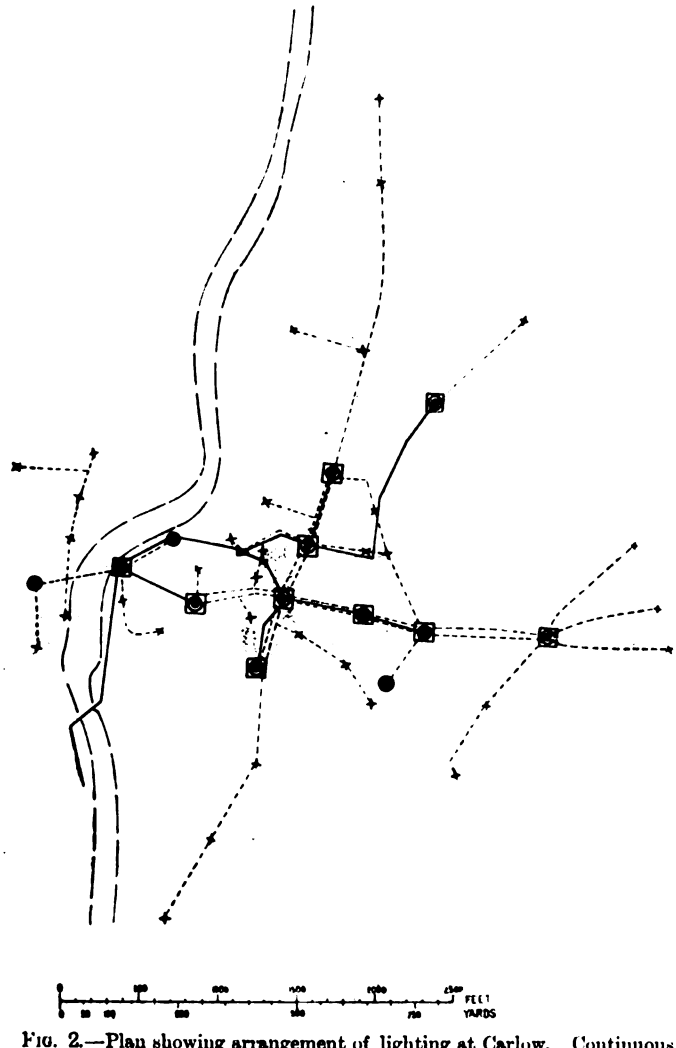


FIG. 2.—Plan showing arrangement of lighting at Carlow. Continuous lines show High-pressure Mains; dotted lines show the Low-pressure Conductors; broken lines show the river; circles represent 8 ampere Brockie-Pell Arc Lamps; stars represent 16-c.p. Glow Lamps. Squares represent Transformers: these are of 4-H P., except those at the extreme North and West which are 2-H.P.

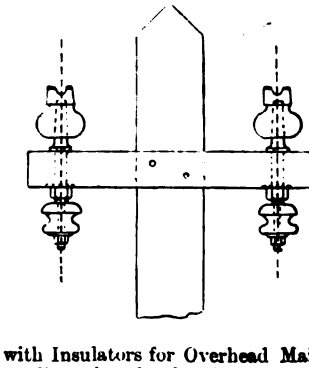

FIG. 4.—Bracket with Insulators for Overhead Mains. The upper insulators carry the suspending wire of galvanised iron; the lower ones carry the 7/16 copper mains.

Digitized by Google

with the vertical, but we rather question whether this figure is to be relied upon as the basis of such an exact calculation as one which includes the figure of 25,840, and we doubt whether as much as 800 candles can be obtained with alternating currents.

The accompanying map (Fig. 2) shows the double system of mains and the public lamps in present use. The outlines of the streets have been omitted to avoid confusion. The main from Milford, five miles distant, enters the town, as shown on the map, from the south-west corner. The conductors are of the Fowler-Waring make. The insulation is carried out in accordance with the Board of Trade regulations, and the actual size is represented in Fig. 3. The cable is carried on steel wire bearers, and Johnson and Phillips' oil insulators are used (Fig. 4), and the average length of span is 150ft. An Elwell-Parker alternating dynamo, capable of giving 45 kilowatts, is employed, the exciter being also of the Elwell-Parker make. Goolden and Co.'s measuring instruments are used. A small switch room, marked by a triangular space on the map, is used for controlling the various circuits. The contractors, in adopting the much-talked-of sub-transformer system, have had to make a guess at the probable consumption, and have erected eight 4-H.P. transformers and two of 2-H.P. Of course, these can be re-arranged when the light is well taken up, and the high-pressure mains can be increased. We hope that customers will come on rapidly, and a fair load will be put upon these transformers, or the economy until this is done will not make a good show. A good feature in the sub station system, if indeed the transformers dotted about the town can be called stations, is that a small customer using two or three lights is *pro ratâ* as good a customer as anybody else. Where transformers are fixed in the houses a rather serious rental is demanded; supply companies indeed may make little out of it, although this rental alone has sufficed to pay a dividend on one occasion, and we are not aware that there is any statutory authority for exacting it. It is very satisfactory to learn that the work has been carried out entirely by local labour; the whole of the erection of poles, placing of machinery, wiring of houses, &c., having been done by the ordinary labourers of the district, of whom between 40 and 50 have been employed ever since the work was commenced in December last.

REVIEWS.

Leçons sur L'Electricite. Par ERIC GERARD. Deuxime Edition. (Paris: Gauthier-Villars. Liége: Léon de Thier. 1891.)

With no servile attempt to cram his readers for some cast-iron examination syllabus, and with no struggle to keep an old book up to date by stuffing it with newspaper cuttings, Prof. Eric Gerard has produced a second edition of his excellent "Lessons" within a few months of their first appearance. For some reason, which is not very clear, we have no such book in this country. A far higher standard is aimed at and maintained, and a much wider ground is covered than has been attempted by any English writer. What Deschanel did for physics, Prof. Gerard has done for the science and applications of electricity. There is no attempt to pass lightly over any subject because a mathematical treatment is required, and there is no struggle after originality. French students are to be envied in having, in two handy volumes, practically the whole of the grounding in electrical science that is necessary for an electrical engineer, and a very useful introduction to the practical side of the subject. This is essentially a modern work, and one which does not attempt to disguise the fact that a considerable portion of its contents are borrowed, with careful editing, from the works of the best writers of the day, and not from books alone, but from technical journals which appeared a remarkably short time before this second edition was published. If any fault is to be found with this book, it is that the introductory part is rather too stiff, but the title should be borne in mind, and it must be remembered that it is put forward as a complete text-book for the classes of the Montefiore Electro-Technical Institute of the University of Liége. We therefore regard from an educational point of view the juggling with C.G.S. units, the theorems about purely mathematical lines of force, the charges on infinitely thin discs and spheres, and the magnetisation of these fascinating forms. But later on there is a good resumé of the work of Hopkinson, Rowland, Barrett, and Ewing, on real magnetism, and a full account of Ewing's development of Weber's molecular theory of magnetisation.

The electrophorus is dismissed in sixteen lines, in the course of a chapter which deals with capacity, condensers, electrometers, and frictional and influence machines. Wheatstone's bridge is led up to by the mazy approach of Kirchoff's tiresome "relations." A short chapter on the energy of the electric current introduces the laws of electrolysis, and concludes the section on electricity. The phenomena of electro-magnetism are analysed into a number of definite laws, equations involving simple differential and integral calculus are given, and the laws are clearly enunciated initalics.

Using the word induction, after Faraday, to express a category of phenomena consisting in the production of a current through conductors, moved in a magnetic field, or subjected to a variable field, the author proceeds to discuss this subject in a short chapter, commencing with Lenz's law, and finishing with the experiments of Ferraris, Elihu Thomson, and Fleming. In the same systematic way, the following chapter deals with the propagation of currents, beginning with Ohm's law and Maxwell's "displacement," and concluding with a brief account of Hertz's discoveries. A practical section is devoted to standards and methods of measurement, but we are surprised to find the Clark cell, though described, meets with no special recommendation, and is followed by an illustrated account of a standard Daniell cell, as used at our Post Office. The Cardew voltmeter is in a like manner followed by a description of an ammeter, which depends on the unequal expansion of a compound metal bar, with no comment on the practical value of either instrument. After a description of batteries and accumulators, the subject of dynamos is introduced, and no space is wasted over the ancient history of Wilde and Wheatstone. This important subject is very well handled, and theory and practice are suitably proportioned. The excellent expression *entrefer* is used for "air-space," but, though it is modelled after several common French words, we do not see how it can be translated into euphonious English. We notice that in a simple diagram of the section of a commutator, the insulation at the end of the bars is omitted, though it is alluded to in the text; there are, however, very few such slips.

The second volume treats of *canalisation* and distribution, methods of calculating the size of conductors, systems of wiring and of feeders, and gives an abstract of the academical network of Herzog and Stark. The sections on meters, cut-outs, motors, traction, and transmission of power are fairly up to date, and are followed by a chapter on electric lighting which begins with sections on incandescent and arc lamps, and proceeds to deal very ably with photometers and the distribution of illumination. Several central stations are described, and the work concludes with a short chapter on electro-metallurgy.

Many of our teachers have no time to write text-books, and we often suspect some reluctance on their part to put in print the teaching which can otherwise be obtained only by attending their classes. On the other hand, it should be admitted candidly that no one man can possibly write such a comprehensive work as this without making considerable use of contemporary literature, and we regret that no one in this country has condescended to set to work with scissors and paste and a blue pencil, and to build up a complete text-book like the Venetians built their palaces; with a foundation composed of solid piles of intelligible conclusions driven through a quagmire of mathematics; with a superstructure largely composed of blocks borrowed from the works of other builders; sometimes hewn into more convenient shape, and sometimes, when more worthy, set up as they found them. The labour is not less than if the whole material had been quarried from a neighbouring mountain, and the whole design is as original as the result is excellent.

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements should be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL PREPAID ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1891 Edition, published on the 23rd February, 1891, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with well-written Biographical Notices of leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1891 should be ordered at once. Price 5s., post free 5s. 9d. Abroad postage extra. Prospectuses free.

ELECTRICAL BOOKS AND PUBLICATIONS

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. Vol. I. Price 7s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Vol. I. Price 6s. 6d., post free.

PATENT OFFICE FEES.

After eight years' experience of the Patent Office reforms introduced by Mr. CHAMBERLAIN, the time has arrived when the question of patent fees may be again considered, and Mr. LENG is to be congratulated on having drawn from the PRESIDENT OF THE BOARD OF TRADE the most satisfactory and practical statement printed in our last issue. In one sense, there was no reduction of fees in 1883, since the total cost of a patent for the full term of fourteen years remained practically the same as before; but the excellent system, giving the option of dividing the charges into easy and gradually increasing payments, amounting to £154, had the immediate effect of encouraging a host of inventors to send in an enormous number of applications. But we have not heard that this influx brought about any real increase in the number of useful inventions which can be said, in the words of Mr. LENG, to contribute to "the advancement of our trade and manufactures, the employment of our people, and the prosperity of the country at large." There is a strong feeling in most minds that inventors should not be taxed for the mere benefit of the revenue, and Sir MICHAEL HICKS-BEACH definitely stated, on the 14th inst., that "he did not think that the country ought to look upon the Patent Office as a permanent source of income." This assurance is noteworthy, as we believe that this is the first time that a member

Digitized by Google

of the Government has conceded the point. Patents have for so many years been regarded as monopolies, that it seemed fair that those who enjoyed the privileges created by the State should contribute handsomely towards the revenue by substantial fees. But we now realise that, to a certain extent, a man has some property in the productions of his mind and imagination, and although no stronger views about property have ever been propounded than are to be heard to-day, we are glad to find that the meddlesome socialism of the time has not attempted to sweep away the patent system. It is possible—but we will not credit them with so much logic—that these modern philosophers recognise that the patent system is one which enables a man to escape competition by paying a fee; and competition, they inform us, is not a healthy stimulant to industry, but a sordid and suicidal policy.

Reduction of the patent fees was the theme of Mr. LENG's speech, but we are not sure whether this is a matter of vital importance. He has done well in ventilating the question, now that we have had several years' experience of the present system, and he has very opportunely compared our charges with those of other nations. The numerous patents in the United States—numerous in spite of their system of examination, may seem to be connected with the small fee of £7. 5s. 10d. for 17 years, as against our £154 for 14 years; but if the former method could be worked simultaneously with our own, and each inventor had the option of selecting the rules and fees, we are inclined to doubt whether the American system would attract the majority. Experienced inventors are thoroughly alive to the fact that the value of an invention cannot possibly be judged at the early stage at which a patent is applied for. Patent Office statistics show, in the most unmistakable manner, that before nine months have elapsed a very considerable proportion of the inventions which have been provisionally protected have turned out unworthy of the £3 fee which then becomes due. In many cases the idea is novel enough, and the method of carrying it out is practicable, but the public do not want it. Very often a patentee does not discover this till several years have elapsed and hundreds of pounds have been expended. For this reason there can be no doubt that the present system of small fees for the first few years is most admirable, but the injustice of the charges for renewals or maintenance is not quite so evident. Four years is generally sufficient to enable the inventor to form an estimate of the value of his work, and it was argued in 1883 that if the patent was not then worth £10 a year it might as well be thrown open to the public. But, on the other hand, there is a great difference between £1 a year, which is paid for the first four years, and £10 a year which is demanded from the end of the fourth to the end of the seventh years; and the view of Sir M. HICKS-BEACH, that the fees charged in the interval between four years and eight years should be reduced, will be welcomed by a large number of inventors. The profits produced by minor inventions frequently fall off after a few years, instead of increasing, as is assumed by present arrangement of fees. Not unfrequently the demand is so limited that, excellent as an invention may be, and though it may go off well at first, everybody who wants it is soon provided, and after a few years the demand may have fallen off so far that the patent fees absorb an important part of the profits. It would be a great boon to the makers and inventors of those many ingenious novelties which form a considerable proportion of the hardware trade, if the patent fees could be rearranged as has been suggested. As each invention comes out and catches on, we wonder how we could have done without it, and six or eight years hence it will have dropped out, not necessarily because it has been pushed aside by an imitation, but because our wants and methods have developed.

The idea of ear-marking the revenue from the Patent Office is excellent, and, while we doubt if it is necessary "to stimulate and encourage inventors," it would tend to reconcile them to the tax if the proceeds were devoted to technical education, and this, not only in our colleges and schools, but in the formation of practical science museums and libraries, which would be useful to the inventors themselves.

The PRESIDENT OF THE BOARD OF TRADE alluded to the abridgements, and raised hopes that these would be proceeded with. Some years ago the abridgements appeared to be a matter of importance to the public and there was much grumbling about them, but no part of the Patent Office work has been more neglected and mismanaged, with the exception, perhaps, of the index. The abridgements have become almost forgotten, and many patentees have never consulted them. They were intended, we believe, for the use of those who could not examine the specifications at the libraries. But many of the provincial patent libraries are completely neglected, and the specifications are piled in heaps in some lumber room in a town-hall. If the local authorities grudge the expense, a small annual grant for binding and shelf accommodation from the Patent Office revenue would enable the provincial inventor to enjoy the same facilities for research as the Londoner. A wary patentee may, with some reason, doubt the competence of anyone but a skilled patent agent to abridge a specification with sufficient accuracy, and, as they do not give the claims, if he means to make any search at all he will prefer to go to the specifications themselves. But the index is not only a standing disgrace to our Patent Office, it is continually being changed in method and arrangement, and even in title. Two very useful volumes of the subject-matter index were produced in 1884 and 1885, and, though the classification was rather peculiar, the brief abstracts were very useful in saving time. But after this one effort, this important part of the index has not only relapsed, but has failed to give the names of the patentees, and, as if to throw more obstacles in the way of the searcher, the alphabetical index has now been removed from the new room. The Illustrated Official Journal, which first appeared in Nov., 1884, is one of the few improvements which have been provided, and we have to thank the Patent Office of the United States for the suggestion, and for showing how it ought to be done. To a large extent it supersedes the abridgements, but the claims should be given in brief to make it really useful. We do not want a popular account of the inventions, but an idea of the patent. The American Journal gives the claims only. A new building is needed, no doubt, and Sir MICHAEL HICKS-BEACH was fully justified in saying that "any more inconvenient buildings, both for the gentlemen employed and the public, he had never seen." But we should first like to see the subject-matter indices brought up to date from 1885, in the style which was then adopted and dropped, references being given to the Illustrated Journal; and proper arrangements made for Patent Office libraries throughout the country. The suggestions of the PRESIDENT OF THE BOARD OF TRADE are important, because, we take it, they are not merely the recommendation of a Government Minister but are practically concessions from the Treasury, that the revenue shall, at all events in part, be devoted to "a more efficient and economical administration of the office." If the revenue is devoted to such objects, and afterwards to the advancement of science museums and libraries, then a reduction in the charges may be considered, and we do not think that the present fees will be out of proportion to the value of a really good patent.

OBITUARY.

WILLOUGHBY SMITH.

It is with deep regret that we announce the death of Mr. Willoughby Smith, which took place at Eastbourne, on the 16th instant, at the age of sixty-three.

The deceased gentleman entered the service of the Gutta Percha Company in the year 1848, and during the years 1849-50 he was busily engaged in the manufacture and laying of a line of copper wire, 30 miles long, and covered with gutta percha, between Dover and Calais. An interesting account of this work was given by him in his "Résumé of the Earlier Days of Telegraphy," published in the *Journal* of the Society of Telegraph Engineers and Electricians, in September, 1881. The trouble and annoyance caused by the imperfect system of making the joints in the experimental line induced Mr. Willoughby Smith to give this subject his special attention, and in the cable laid over the same course in the following year he introduced a system of joint-making which proved a great success, and, in 1855, the present system of joining and insulating the conductor. In 1852 he was engaged in the manufacture and laying of the Holyhead and Howth, Port Patrick and Donaghadee cables, and in the manufacture of the cables laid from Orford Ness to the Hague. In the same year he was also engaged in laying gutta-percha covered copper wire in a trench dug in the "six foot" of the Manchester and Liverpool line. In 1853 he had charge of the laying of ten copper wires, insulated separately with two coverings of gutta-percha, then laid longitudinally together and bound with tarred hemp, and placed in a wooden trough, in a trench made by the side of the old coach road from London to Manchester, and from Preston to Liverpool. Early in 1854, the first cable to be laid in the Mediterranean was commenced. Mr. Willoughby Smith had charge of the electrical department during its manufacture, and assisted Prof. Wheatstone with his experiments on the retardation of signals through this cable, while coiled at the works. These experiments were made for the purpose of verifying or correcting the results of similar experiments which had been made by Faraday on lengths of the core of this cable earlier in the same year. Mr. Willoughby Smith took charge of the electrical department during the laying of this cable between Spezzia and Corsica, Corsica and Sardinia, and in the following year was similarly employed in the manufacture and laying of a cable between Sardinia and Bona.

On his return from this expedition he remained at home as electrician and manager of the wire department at the Gutta Percha Works, and at once commenced to prepare for the manufacture of 2,500 miles of core for a cable which was to be laid from Ireland to Newfoundland. In 1851, after the manufacture of the single-covered copper wire laid from Dover to Calais, it was thought advisable to apply the gutta-percha in two or more thin, instead of one thick, coverings, and to insure adhesion between these separate coverings, coal-tar naphtha was employed. Time, however, showed that this solvent was very prejudicial to the durability of the gutta-percha, and in 1858 Mr. Willoughby Smith invented an insulating and adhesive compound suitable for application between each covering of the gutta-percha, instead of the coal-tar naphtha hitherto employed. This compound was soon adopted, and is in general use at the present time. In 1864 the works of Messrs. Glass, Elliot, and Co., at Greenwich, and the Gutta Percha Company were formed into "The Telegraph Construction and Maintenance Company."

In 1865 the late Sir Richard Glass, the then Managing Director of the Telegraph Construction and Maintenance Company, requested Mr. Willoughby Smith to accompany the "Great Eastern," and render assistance, if necessary, in the laying of the cable from Ireland to Newfoundland. After laying 1,200 miles, and while endeavouring to recover a fault, the cable parted. After many endeavours to recover the cable the expedition returned to refit, but ultimately it was considered that the year was too far advanced to continue such operations in mid-Atlantic. Mr. Willoughby Smith considered the electrical system employed on the occasion imperfect, inasmuch as it allowed faults, which were evidently caused on board, to pass miles astern before they were known to exist; he therefore devised a system which would keep a continuous insulation test on the whole of the cable, and allow ship and shore to converse freely through it without interfering with either the insulation or continuity tests. A very interesting account of the system is to be found in "The Working of Long Submarine Cables," a Paper read before the Society of Telegraph Engineers and Electricians, in February, 1879. Early in 1866 Mr. Willoughby Smith was appointed chief electrician to the Telegraph Construction and Maintenance Company, and in that capacity was engaged on board the "Great Eastern" during the successful laying of the cable from Ireland to Newfoundland, and the recovery and completion of the cable lost the previous year. On the return of the "Great Eastern" those who had achieved so much were much *fêted*, and the American Chamber of Commerce at Liverpool had four massive gold medals struck, and, at a public banquet given in that city, presented them to Sir James Anderson, captain of the "Great Eastern;" Sir Samuel Canning, engineer of the expedition; Willoughby Smith, electrician to the expedition; and Cyrus W. Field, chief of the originators of the enterprise.

In June, 1869, Mr. Willoughby Smith was again on board the "Great Eastern," in charge of the electrical department of the "French" Atlantic Cable. This cable was successfully laid from Brest to St. Pierre. About this time the use of india-rubber in place of gutta-percha for insulating the conductors of submarine cables was being strongly advocated on account of its comparatively low specific inductive capacity; but Mr. Willoughby Smith showed how the specific inductive capacity of gutta-percha could be reduced to an equality with, if not below, that of india-rubber. He submitted samples of core so manufactured to gentlemen eminently qualified to report upon them, and they reported that the specific inductive capacity of what was termed "Willoughby Smith's gutta-percha" was 18 per cent. lower than that of ordinary gutta-percha. This was an important discovery, as the amount represented a similar percentage of increased speed in conductors insulated with gutta-percha.

Mr. Willoughby Smith was intimately connected with the Institution of Electrical Engineers from its commencement, and he has communicated the following Papers to it:—"Underground Telegraphs," "The Effect of Light on the Electrical Qualities of Selenium," "The Working of Long Submarine Cables," "A Résumé of the Early Days of Electric Telegraphy," "Volta Electric Induction." In 1882 he was elected its president, and in January, 1883, delivered his inaugural address, which was published in the Society's *Journal*. In addition to the above, Mr. Smith has published the following Papers:—"Induction," 1882; "Volta and Magneto-Electric Induction," read before the Royal Institution, June 6th, 1884; "Induction and Conduction," 1885; and "Magnetism," 1885. In December, 1887, Mr. Willoughby Smith severed his connection with the Telegraph Construction and Maintenance Company, but he still took an interest in things electrical, as was instanced by his system for telegraphic communication without metallic contact, noticed in *The Electrician*. Only a few weeks ago, he published his book on "The Rise and Extension of Submarine Telegraphy." From the preface it appears that he contemplated writing on Subterranean Telegraphy and Electric Lighting, and it would have been interesting to have had his views on these subjects.

Mr. Willoughby Smith was a man of great force of character, possessed of strong common sense, great perseverance, rarely giving up anything until he had solved the problem in hand, and a hard and industrious worker. A firm friend and genial companion, his death will leave a blank in the lives of many friends.

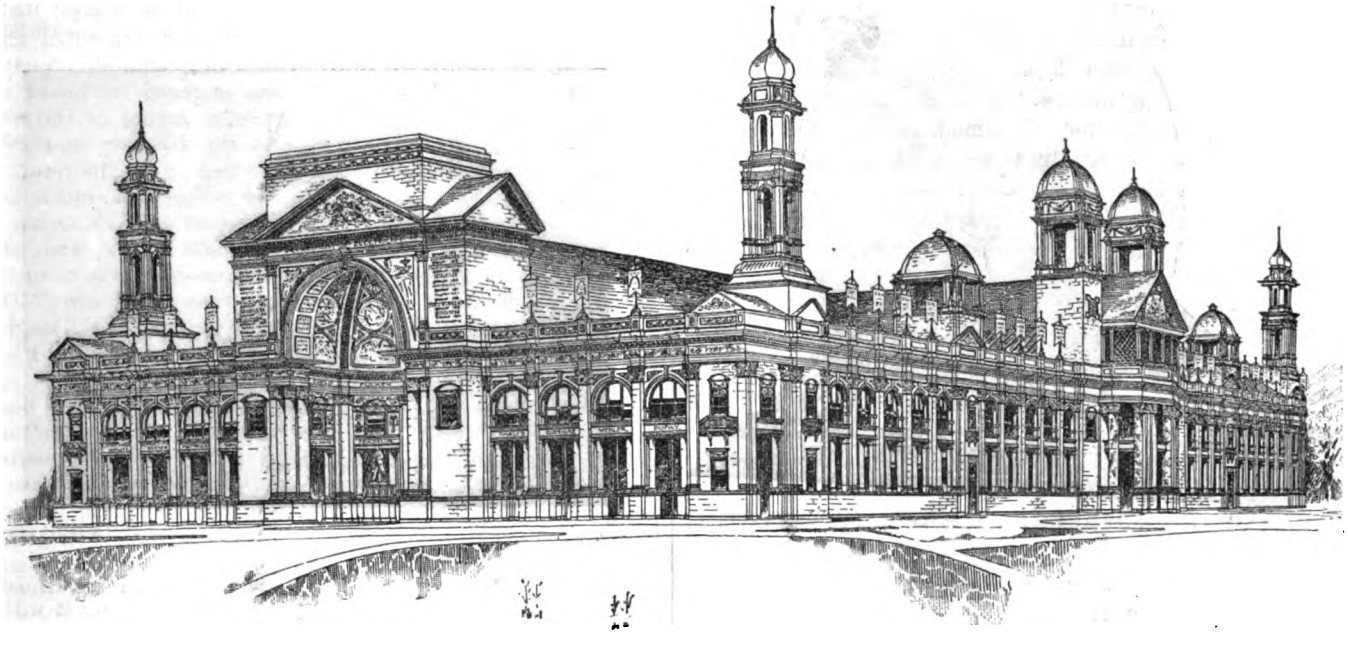
THE ELECTRICAL BUILDING AT THE CHICAGO EXHIBITION.

A number of plans for the arrangement of the grounds of the exhibition at Chicago, and several designs for the buildings, have been put forward, and several of these, after having been published, have been withdrawn. We understand that the building provided for the electrical exhibits has actually been begun, and the accompanying illustration gives a good idea of its general appearance.

The building covers a space of 700 by 350ft., or more than five and one-half acres. Like most of the other buildings, the style of architecture is highly decorative, and is, we understand, supposed to be Italian Renaissance. It is 60ft. high and ornamented with designs suggestive of the department. It is one of the handsomest of the grand central group, and will cost $650,000. There will be four entrances to the building, the main one on the south. It is being built of a material resembling granite in colour.

A statue of Franklin will rise conspicuously before the south entrance.



EXPERIMENTS WITH ALTERNATE CURRENTS OF VERY HIGH FREQUENCY, AND THEIR APPLICATION TO METHODS OF ARTIFICIAL ILLUMINATION.*

BY NIKOLA TESLA.

The phenomena which are peculiar to the changing character of the currents are greatly exalted when the rate of change is increased, hence the study of these currents is considerably facilitated by the employment of properly constructed apparatus. It was with this and other objects in view that I constructed alternate-current machines capable of giving more than two million reversals of current per minute. The investigator who desires to repeat the experiments which I describe, with an alternate current machine, capable of supplying currents of the desired frequency, and an induction coil, will do well to take the primary coil out and mount the secondary in such a manner as to be able to look through the tube upon which the secondary is wound. He will then be able to observe the streams which pass from the primary to the insulating tube, and from their intensity he will know how far he can strain the coil. The selection of the type of machine best suited for the purpose must be left to the judgment of the experimenter. There are here illustrated three distinct types of machines, which, besides others, I have used in my experiments. Fig. 1 represents the machine used in my experiments before this Institute. It caused me the least trouble in construction as well as in maintenance, and, on the whole, it has been a good experimental machine. The field magnet consists of a ring of wrought iron with 384 pole projections. The armature comprises a steel disc to which is fastened a thin, carefully welded rim of wrought iron. Upon the rim are wound several layers of fine, well annealed iron wire, which, when wound, is passed through shellac. The armature wires are wound around brass pins, wrapped with silk thread. The diameter of the armature wire in this type of machine should not be more than one-sixth of the thickness of the pole projections, else the local action will be considerable. From the behaviour of the dielectrics in these experiments we may conclude that the best insulator for these rapidly alternating currents would be the one possessing the smallest specific inductive capacity, and at the same time one capable of withstanding the greatest differences of potential; and thus two diametrically opposite ways of securing the required insulation are indicated, namely, to use either a perfect vacuum or a gas under great pressure; but the former would be preferable. Unfortunately, neither of these two ways is easily carried out in practice. To avoid misunderstanding in regard to the physiological effect of alternating currents of very high frequency, I think it necessary to state that while it is an undeniable fact that they are incomparably less dangerous than currents of low frequencies, yet it should not be thought that they are altogether harmless.

After referring to the differences which may be observed between the brush discharges obtained by means of a rapidly alternating induction coil, when compared with that obtained from a powerful static machine, Mr. Tesla described the following striking peculiarity of the brush discharge produced by very rapidly alternating currents. To observe this it is best to replace the usual terminals of the coil by two metal columns insulated with a good thickness of ebonite. It is also well to close all fissures and cracks with wax so that the brushes cannot form anywhere except at the tops of the columns. If the conditions are carefully adjusted so that the potential rises to an enormous value, one may produce two powerful brushes several inches long, nearly white at their roots, which, in the dark, bear a striking resemblance to two flames of a gas escaping under pressure (Fig. 2). But they do not only *resemble*, they *are* veritable flames, for they are hot. Certainly they are not as hot as a gas burner, *but they would be so if the frequency and the potential should be sufficiently high.* Produced with, say, 20,000 alternations per second, the heat is easily perceptible even if the potential is not excessively high. If a bulb be held over the terminal of the coil so as to inclose the brush, the air contained in the bulb is very quickly brought to a high temperature. If a glass tube be held over the brush so as to allow the draught to carry the brush upward, scorching hot air escapes at the top of the tube. Anything held within the brush is, of course, rapidly heated, and the possibility of using such heating effects for some purpose or other suggests itself. It is of no little interest to contemplate that we have a possible way of producing—by other than chemical means—a veritable flame which would give light and heat without any material being consumed, without any chemical process taking place, and to accomplish this we only

* Extracts from a lecture delivered before the American Institute of Electrical Engineers, at Columbia College, May 20, 1891.

Digitized by Google

need to perfect methods of producing enormous frequencies and potentials. I have no doubt that if the potential could be made to alternate with sufficient rapidity and power, the brush formed at the end of a wire would lose its electrical characteristics, and would become flamelike. The flame must be due to electrostatic molecular action.

By preventing completely the exchange of the air molecules the local heating effect may be so exalted as to bring a body to incandescence. Thus, for instance, if a small button, or preferably a very thin wire or filament, be enclosed in an unexhausted globe and connected with the terminal of the coil, it may be rendered incandescent. The phenomenon is made much more interesting by the rapid spinning round in a circle of the top of the filament, thus presenting the appearance of a luminous funnel (Fig. 3), which widens when the potential is increased. When the potential is small the end of the filament may perform irregular motions, suddenly changing from one to the other, or it may describe an ellipse; but when the potential is very high it always spins in a circle; and so does, generally, a thin, straight wire attached freely to the terminal of the coil. These motions are, of course, due to the impact of the molecules and the irregularity in the distribution of the potential, owing to the roughness and dissymmetry of the wire or filament. With a perfectly symmetrical and polished wire such motions would probably not occur. That the motion is not likely to be due to other causes is evident from the fact that it is not of a definite direction, and that in a very highly exhausted globe it ceases altogether. The possibility of bringing a body to incandescence in an unexhausted globe, or even when not at all enclosed, would seem to afford a possible way of obtaining lighting effects, which by perfecting methods of producing rapidly alternating potentials might be rendered available for useful purposes.

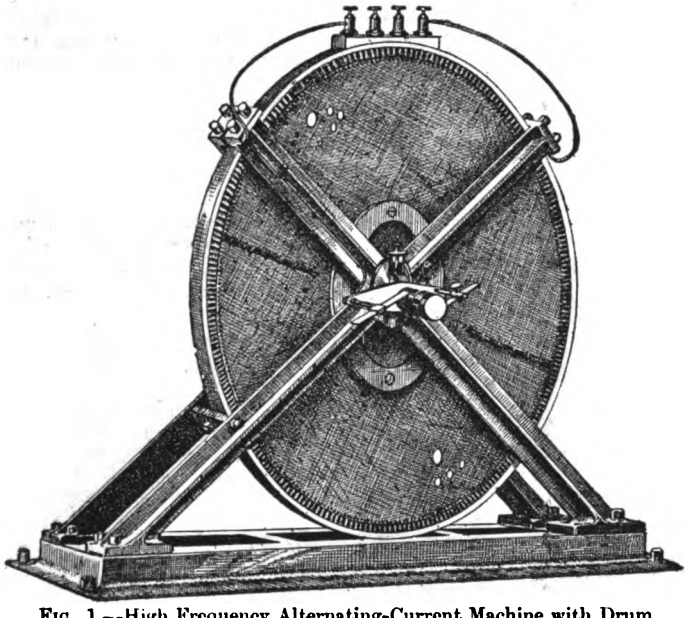


FIG. 1.—High Frequency Alternating-Current Machine with Drum Armature.

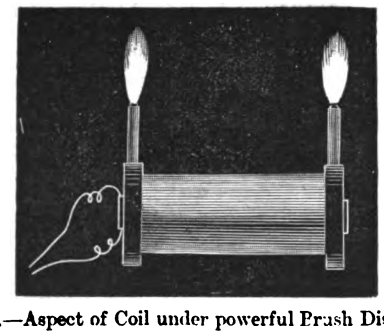

FIG. 2.—Aspect of Coil under powerful Brush Discharge.

Of all the experiments which may be performed with rapidly alternating currents, the most interesting are those which concern the production of a practical illuminant. Modern research has opened new possibilities for the production of an efficient source of light, and the attention of all has been carried in the direction indicated by able pioneers. Many have been carried away by the enthusiasm and passion to discover, but in their zeal to reach results many have been misled. Starting with the idea of producing electro-magnetic waves, they turned their attention, perhaps, too much to the study of electro-magnetic effects and neglected the study of electrostatic phenomena. Naturally, nearly every investigator availed himself of an apparatus similar to that used in earlier experiments. But in those forms of apparatus, while the electromagnetic inductive effects are enormous, the electrostatic effects are excessively small.

It has occurred to me, however, that electrostatic effects are in many ways available for the production of light. The electrostatic effects being dependent upon the potential and frequency, to produce the most powerful action it is desirable to increase both as far as practicable. It may be possible to obtain quite fair results by keeping either of these factors small, provided the other is sufficiently great; but we are limited in both directions. My experience demonstrates that we cannot go below a certain frequency, for, first, the potential then becomes so great that it is dangerous; and, secondly, the light production is less efficient.

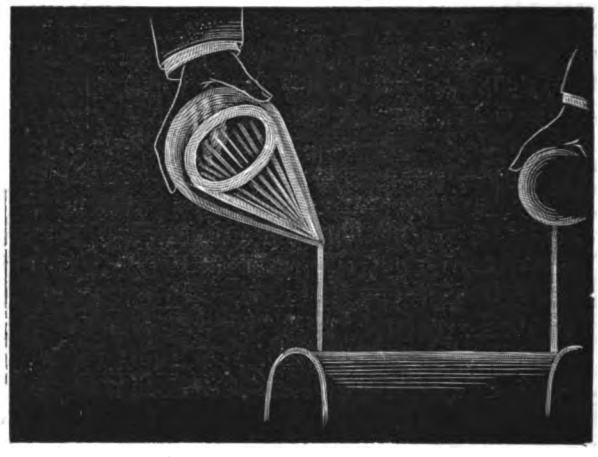

FIG. 3.—Incandescent Wire or Filament spinning in an Exhausted Globe.

I have stated above that a body enclosed in an unexhausted bulb may be intensely heated by simply connecting it with a source of rapidly alternating potential. The success of lamps of this kind would depend largely on the selection of the light-giving bodies contained within the bulb. Since, under the conditions described, refractory bodies—which are very poor conductors and capable of withstanding for a long time excessively high degrees of temperature—may be used, such illuminating devices may be rendered successful. It might be thought at first that if the bulb containing the filament or button of refractory material be perfectly well exhausted—that is, as far as it can be done by the use of the best apparatus—the heating would be much less intense, and that in perfect vacuum it could not occur at all. This is not confirmed by my experience; quite the contrary. The better the vacuum the easier the bodies are brought to incandescence. This result is interesting for many reasons.

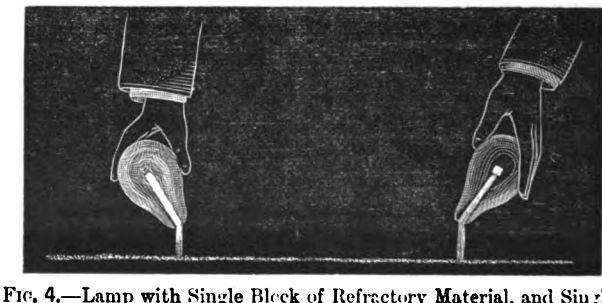

FIG. 4.—Lamp with Single Block of Refractory Material, and Single Filament Lamp.

Various forms of lamps on the above-described principle with the refractory bodies in the form of filaments have been constructed and operated by me, and investigations are being carried on in this line. There is no difficulty in reaching such high degrees of incandescence that ordinary carbon is to all appearance melted and volatilised. If the vacuum could be absolutely perfect such a lamp, although inoperative with apparatus ordinarily used, would, if operated with currents of the required character, afford an illuminant which would never be destroyed, and which would be far more efficient than an ordinary incandescent lamp. This perfection can, of course, never be reached, and a very slow destruction and gradual diminution of the size always occurs, as in incandescent lamps; but there is no possibility of a sudden and premature disabling which occurs in the latter by the breaking of the filament, especially when the incandescent bodies are in the shape of blocks. With these rapidly alternating potentials there is, however, no necessity of enclosing two blocks in a globe, but a single block, as in

Digitized by Google

Fig. 4, may be used. The potential in this case must, of course, be higher, but it is easily obtainable, and besides it is not necessarily dangerous.

The facility with which the button or filament in such a lamp is brought to incandescence, other things being equal, depends on the size of the globe. The life of such lamps as described above depends, of course, largely on the degree of exhaustion, but to some extent also on the shape of the block of refractory mater al.

The use of alternating currents of very high frequency makes it possible to transfer, by electrostatic or electro-magnetic induction through the glass of a lamp sufficient energy to keep a filament at incandescence, and so do away with the leading-in wires. Such lamps have been proposed, but for want of proper apparatus they have not been successfully operated. Many forms of lamps on this principle, with continuous and broken filaments, have been constructed by me and experimented upon. When using a secondary enclosed within the lamp, a condenser is advantageously combined with the secondary. When the transference is effected by electrostratic induction, the potentials used are, of course, very high with frequencies obtained from a machine. For instance, with a condenser surface of 40 centimetres square, which is not impracticably large, and with glass of good quality, 1 millimetre thick, using currents alternating 20,000 times a second, the potential required is, approximately, 9,000 volts. This may seem large, but since each lamp may be included in the secondary of a transformer of very small dimensions, it would not be inconvenient, and, moreover, it would not produce fatal injury. The transformers would all be preferably in series. The regulation would offer no difficulties, as with currents of such frequencies it is very easy to maintain a constant current

The experiments which will prove most suggestive and of most interest to the investigator are probably those performed with exhausted tubes. During my investigations in this line I endeavoured to excite tubes, devoid of any electrodes, by electro-magnetic induction, making the tube the secondary of the induction device, and passing through the primary the discharges of a Leyden jar. These tubes were made of many shapes, and I was able to obtain luminous effects which I then thought were due wholly to electro-magnetic induction. But, on carefully investigating the phenomena, I found that the effects produced were more of an electrostatic

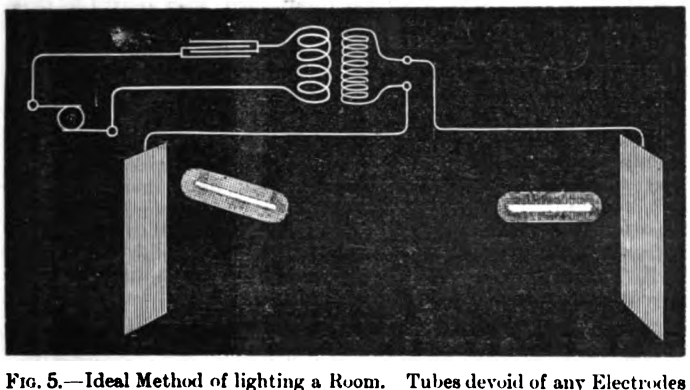

Fig. 5.—Ideal Method of lighting a Room. Tubes devoid of any Electrodes rendered brilliant in an Alternating Electrostatic Field.

nature. It may be attributed to this circumstance that this mode of exciting tubes is very wasteful; namely, the primary circuit being closed, the potential, and consequently the electrostatic inductive effect, is much diminished. When an induction coil, operated as above described, is used, there is no doubt that the tubes are excited by electrostatic induction, and that electro-magnetic induction has little, if anything, to do with the phenomena.

This is evident from many experiments. For instance, if a tube be taken in one hand, the observer being near the coil, it is brilliantly lighted, and remains so, no matter in what position it is held relatively to the observer's body. Were the action electro-magnetic, the tube could not be lighted when the observer's body is interposed between it and the coil, or at least its luminosity should be considerably diminished. When the tube is held exactly over the centre of the coil—the latter being wound in sections, and the primary placed symmetrically to the secondary—it may remain completely dark, whereas it is rendered intensely luminous by moving it slightly to the right or left from the centre of the coil. It does not light because in the middle both halves of the coil neutralise each other, and the electric potential is zero. If the action were electro-magnetic, the tube should light best in the plane through the centre of the coil, since the electro-magnetic effect there should be a maximum. When an arc is established between the terminals, the tubes and lamps in the vicinity of the coil go out, but light up again when the arc is broken, on account of the rise of potential. Yet the electro-magnetic effect should be practically the same in both cases.

By placing a tube at some distance from the coil, and nearer to one terminal—preferably at a point on the axis of the coil—one may light it by touching the remote terminal with an insulated body of some size, or with the hand, thereby raising the potential at that terminal nearer to the tube. If the tube is shifted nearer to the coil, so that it is lighted by the action of the nearer terminal, it may be made to go out by holding, on an insulated support, the end of a wire connected to the remote terminal in the vicinity of the nearer terminal, by this means counteracting the action of the latter upon the tube. These effects are evidently electrostatic. Likewise, when a tube is placed at considerable distance from the coil, the observer may, standing upon an insulated support, between the coil and tube, light the latter by approaching the hand to it; or he may even render it luminous by simply stepping between it and the coil. This would be impossible with electro-magnetic induction, for the body of the observer would act as a screen.

The effects of screening also indicate the electrostatic nature of the phenomena, and show something of the nature of electrification through the air. For instance, if a tube be placed in the direction of the axis of the coil, and an insulated metal plate be interposed, the tube will generally increase in brilliancy, or if it be too far from the coil to light, it may even be rendered luminous by interposing an insulated metal plate. The magnitude of the effects depends to some extent on the size of the plate. But if the metal plate be connected by a wire to the ground, its interposition will always make the tube go out, even if it be very near the coil.

In all the cases, then, when we excite luminosity in exhausted tubes by means of such a coil, the effect is due to the rapidly alternating electrostatic potential; and, furthermore, it must be attributed to the harmonic alternation produced directly by the machine, and not to any superimposed vibration which might be

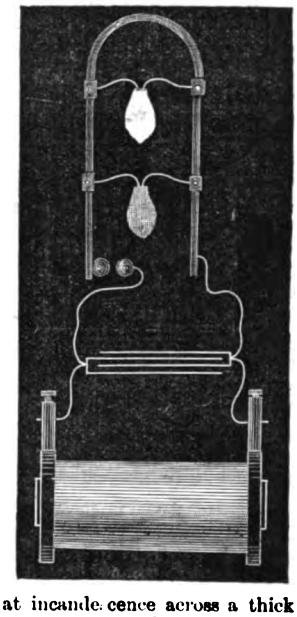

Fig. 6.—Lamp kept at incandescence across a thick Copper Bar, showing nodes.

thought to exist. Such superimposed vibrations are impossible when we work with an alternate current machine. If a spring be gradually tightened and released, it does not perform independent vibrations; for this a sudden release is necessary. So with the alternate currents from a dynamo machine; the medium is harmonically strained and released, this giving rise to only one kind of waves; a sudden contact or break, or a sudden giving way of the dielectric, as in the disruptive discharge of a Leyden jar, are essential for the production of superimposed waves.

In all the last described experiments, tubes devoid of any electrodes may be used, and there is no difficulty in producing by their means sufficient light to read by. The light effect is, however, considerably increased by the use of phosphorescent bodies, such as yttria, uranium glass, &c. A difficulty will be found when the phosphorescent material is used, for with these powerful effects it is carried gradually away, and it is preferable to use material in the form of a solid.

Instead of depending on induction at a distance to light the tube, the same may be provided with an external—and, if desired, also with an internal—condenser coating, and may then be suspended anywhere in the room from a conductor connected to one terminal of the coil, and in this manner a soft illumination may be provided.

The ideal way of lighting a hall or room would, however, be to produce such a condition in it that an illuminating device could be moved and put anywhere, and that it is lighted no matter where it is put, and without being electrically connected to anything. I

Digitized by Google

have been able to produce such a condition by creating in the room a powerful, rapidly alternating electrostatic field. For this purpose I suspend a sheet of metal at a distance from the ceiling, on insulating cords, and connect it to one terminal of the induction coil, the other terminal being preferably connected to the ground. Or else I suspend two sheets, as illustrated in Fig. 5, each sheet being connected with one of the terminals of the coil, and their size being carefully determined. An exhausted tube may then be carried in the hand anywhere between the sheets or placed anywhere, even a certain distance beyond them; it remains always luminous.

In operating my devices I have observed curious phenomena of impedance, which are of interest. For instance, if a thick copper bar be bent, as indicated in Fig. 6, and shunted by ordinary incandescent lamps, then, by passing the discharge between the knobs, the lamps may be brought to incandescence although they are short circuited. When a large induction coil is employed it is easy to obtain nodes on the bar which are rendered evident by the different degrees of brilliancy of the lamps. When lamps with long, slender filaments are used it will be often noted that the filaments are from time to time violently vibrated. This vibration seems to be due to an electrostatic action between the filament and the glass of the bulb. In some of the above experiments it is preferable to use special lamps having a straight filament. When such a lamp is used a still more curious phenomenon than those described may be observed. The lamp may be placed across the copper bar and lighted, and by using somewhat larger capacities, or, in other words, smaller frequencies, or smaller impulsive impedances, the filament may be brought to any desired degree of incandescence. But when the impedance is increased, a point is reached when comparatively little current passes through the carbon and most of it through the rarefied gas; or, perhaps, it may be more correct to state that the current divides nearly evenly through both, in spite of the enormous difference in the resistance, and this would be true unless the gas and the filament behave differently. It is then noted that the whole bulb is brilliantly illuminated, and the ends of the leading-in wires become incandescent, and often throw off sparks in consequence of the violent bombardment; but the carbon filament remains dark. Instead of the filament a single wire extending through the whole bulb may be used, and in this case the phenomenon would seem to be still more interesting.

In presenting to you these results of my investigation on the subject under consideration I have paid only a passing notice to facts upon which I could have dwelt at length, and among many observations I have selected only those which I thought most likely to interest you. The field is wide and completely unexplored, and at every step a new truth is gleaned, a novel fact observed.

ELECTROLYSIS BY MEANS OF THE ALTERNATING CURRENT.

BY DR. GUGLIELMO MENGARINI.

(Concluded from page 303.)

Effect Produced by a High Current Density at one of the Electrodes.

If a platinum and acidulated water voltameter is traversed by an alternating current, which by means of an adjustable resistance can be kept at a constant value whilst the surface of one of the electrodes is gradually diminished, a point is reached at which the current density at the movable electrode becomes so great that large bubbles of gas are evolved, which for a moment insulate a portion of the electrode from the liquid. The metallic surface is then capable of igniting the bubbles of gas, producing small explosions and flashes of light in the liquid. With care it is possible to render the electrode incandescent along its whole length, so that it is covered with a sheet of flame from which dart flashes of bluish light with little explosions. At the same time on the first electrode, where the current density has remained constant, appears a copious evolution of gas, without comparison greater than it was at first, when the other electrode did not exhibit this phenomenon of recombination. This gas is found to be a mixture very rich in hydrogen. If it is a salt that is being decomposed, a considerable deposit of metal takes place on the second electrode, which is seen by simple inspection, without the necessity of weighing, to be very much greater than that which would have taken place under ordinary conditions. If on the electrode whose surface has been kept constant, the current density is so small that no trace of decomposition appears on it; still, as soon as the first electrode commences to be incandescent, the products of decomposition immediately appear on the second, which, in the case of solid ions, at once becomes covered with a metallic deposit, just as if it formed the negative electrode of a voltameter traversed by a direct current.

A similar result occurs if one of the electrodes, without being covered by a sheet of gas from which starts a continuous series of explosions, is surrounded by liquid in a state of strong ebullition, so that, without any luminous phenomena, the electrode gives out a feeble sound resembling the hum of a gnat. In order to carry out this experiment, it is sufficient to enclose the electrode in a porous cell immersed in the liquid. After starting the current, as soon as the density reaches a suitable value the liquid enters into ebullition.

If a third electrode of platinum is placed in the voltameter containing the two electrodes when the above experiments are being made, and a wire carried from it to one terminal of a galvanometer, the other terminal of which can be connected by means of a key to either of the two original electrodes, it is found on suddenly breaking the alternating circuit, that whilst the electrode that became incandescent is either not polarised at all, or only very feebly so, that with the larger surface shows strong polarisation, the direction of the current being the same as that from the copper pole of a volta couple.

On inserting other voltameters containing sulphate of copper, nitrate of silver, &c., in series with the first, and placing therein electrodes of such an area that decomposition does not occur when the alternating current passes through them, as soon as the above phenomenon takes place, the current remaining constant, an active electrolytic decomposition commences with deposition of copper, silver, &c., in each of the other voltameters.

Real and Apparent Energy Expended in Voltameters Traversed by Alternating Currents.

If in an alternating current circuit an acidulated water voltameter is replaced by a wire of equal resistance, the current will be increased; and if several voltameters, all of equal resistance, are constructed with electrodes of different areas, and successively inserted in the circuit, it will be found that that with the smallest electrode area will give the greatest current. This experiment was made by Kohlrausch in 1873*, and he deduced from it that it was not possible to apply Ohm's law to liquid conductors, and was forced to admit that the small quantity of gas produced by an alternation developed an appreciable electromotive force.

The investigations given above show that the phase of the difference of potential at the voltameter poles is displaced with regard to that of the current, and that polarisation, like self-induction, does not interfere with the sinoidal character of the alternating current, but that the new curve obtained by the action of either of these two causes is displaced and diminished with regard to that which would have been found if neither polarisation or self-induction had been present. Consequently, the energy really expended at any instant in a voltameter traversed with an alternating current cannot be measured by the product of the current as determined by an electro-dynamometer, and the potential difference between the voltameter poles as determined by an electrometer or a Cardew voltmeter, but a wattmeter has to be used. I had a very sensitive one with a reflecting mirror made for me by Messrs. Ganz and Co., of Budapest, which was capable of measuring very exactly the work expended in a conductor of low resistance traversed by feeble currents. The errors introduced by the instrument through the want of perfect synchronism in the currents in the two circuits, owing to self-induction in the movable coil,† were in my case absolutely negligible.

A series of 13 experiments, made with 8 equal voltameters constructed of platinum wire of an area of ·785 square centimetres each, supplies a good example of the way in which the energy really expended in the voltameters (as measured by the wattmeter) diminishes in comparison with that apparently expended (as measured by the indications of a mirror voltameter, comparable to a Cardew, and an electro-dynamometer) as the current density at the electrodes is diminished and the quantity of gas evolved is reduced. At starting, a current I of 1·798 ampere was used, which was gradually decreased, readings being simultaneously taken with the reflecting wattmeter, the reflecting voltmeter, and the electro-dynamometer. The following table gives the results of the measurements:—

I.	W.	V × A.	W/V × A.	Remarks.

In this series of experiments, the voltameters having equal electrode areas, and being placed in series, the same amount of gas was produced in each. In another set of experiments, in which the electrodes were of different areas, so that, being still in series, for the different current density on the electrodes, the amounts of gas liberated were also different. Four voltameters were placed in series, and in each one of the two platinum electrodes had a surface of such size that, with a current of 2 amperes, no decomposition was apparent at it. The surfaces of the other electrode in each voltameter were as follows :—

Voltameter I. = 0·5110 sq. cent.
" II. = 0·7386 "
" III. = 1·5606 "
" IV. = 3·1056 "

The results obtained are given in the annexed Table :—

Mean number of alternations, 85·5 per sec.

This second series of observations is given to show that, whether the current traversing the voltameter remains practically constant or is allowed to vary between narrow limits, if the difference of potential between the poles of the voltameters is reduced, a continually increasing diminution takes place in the ratio between the real and the apparent energy absorbed in the voltameters. This alteration in the ratio can be readily explained, and is a consequence of the principles already given.

In order to facilitate the consideration of the question we will assume that the expression for the polarisation holds good for high values of the latter. Although this is not absolutely true, still to make our reasoning correct it is not only necessary to substitute for the sine function employed that which really expresses the polarisation, we have already proved that the difference of potential at any instant between the poles of a voltameter traversed by an alternating current is equal to the potential difference between the extremities of an equal resistance without induction or capacity, plus the value assumed at the instant by the electromotive force of polarisation. The curve representing the former function is sinoidal, and synchronous with that giving the current ; that representing the second is only sinoidal so long as decomposition in the voltameter does not take place ; if decomposition does occur the curve is made up of portions of sine curves connected by straight lines parallel to the axis of abscissæ.

The resultant of the two curves of potential difference and polarisation in the case when decomposition does not occur, is a new sine curve, such as V V′ V″ (Fig. 1), the resultant of O B T, P P′ P″, and in this case the phase of V V′ V″ will be found to be as far displaced as possible from that of current, which is represented by O A T. If, by increasing the current density at the electrodes or reducing the number of alternations, electrolytic decomposition is started and subsequently increases, the sine curve O B T synchronous with O A T (Fig. 1) must be combined with C M N (Fig. 2), or with C M_1 N_1, and it follows that the resultant is no longer a sine curve but a deformed curve, of which the phases approach more closely to those of the current as the straight lines M N, M_1 N_1 become longer, that is, the greater is the quantity of electrolyte decomposed.

In the limiting case when the amount of the electrolyte decomposed by an alternating current is equal to that which would have been decomposed by a continuous current giving equal quantity, the curve corresponding to C M N will coincide with the axis O T, and the phase of V V_1 V_2 will, in the result, be synchronous with that of the current. In such a limiting case, the amounts of energy really and apparently expended in the voltameter will be identical.

There is a very great similarity between an electrical transformer and a voltameter traversed by an alternating current. The resistance of the secondary circuit in the transformer, and the quantity of the electrolyte decomposed in the voltameter, exercise precisely similar effects on the current. When the external resistance in the secondary circuit of a transformer is zero, the phases of potential difference and current are very near to synchronism, and the same thing is true when there is no difference between the amounts of an electrolyte decomposed by an alternating current and by a continuous current giving equal quantity. When the external resistance of the secondary of the transformer is infinite, and electrolytic decomposition does not take place at all in the voltameter, the difference between the two phases reaches its maximum. The same thing may also be said for the difference between the energies really and apparently consumed in the voltameter.

Experiments with Interrupted Direct Currents.

Platinum is the only metal which is not acted upon when it is used as an electrode for the electrolysis of water by means of a direct current ; when other metals are used the positive electrode is seen to become covered with a black or brown film which, after having reached a certain thickness, finally stops the internal development of hydrogen at the negative poles. The layer of brown powder formed round the positive electrode is then seen to dissolve, and then the electrode itself is vigorously attacked.* The positive electrode may thus be completely dissolved, but this, of course, requires a considerable space of time. Gold is not an exception to this rule, as it becomes covered with a dark red powder at the positive pole. Platinum, however, is not acted upon, but both poles remain quite bright, even when the duration of the current is considerable.

On the other hand, in electrolysis with an alternating current, the film of brown powder quickly appears at both platinum electrodes when feeble or strong currents are used. Consequently, the properties of platinum, in conjunction with alternating and continuous currents, are very different. The difference, however, disappears

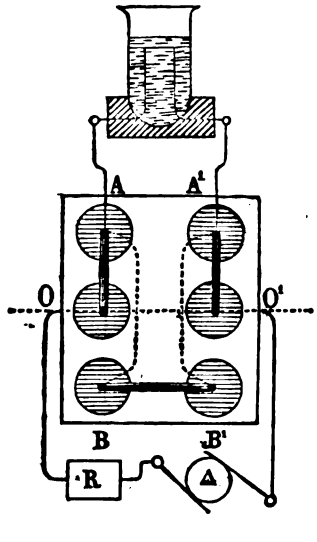

Fig. 4.

when, instead of direct continuous currents, we use direct currents made to alternate by means of a commutator, or (which is more important) when direct intermittent currents are used, and the voltameter is so arranged that it is short circuited at the conclusion of any current impulse and remains so until the commencement of the next.

In order to study this phenomenon, I made use of the apparatus represented in Fig. 4. An oscillating interruptor, consisting of six mercury cups, was constructed, its movable part being a plate of ebonite, above which were placed three pieces of copper wire terminating at the six points A A′, B B′, O O′ ; when the ebonite plate oscillates about the axis O O′, contact is made between the wires and the cups, either at A A′, or at B B′. The wires from an acidulated water voltameter were connected to the mercury cups under A A′. The leads from a direct-current dynamo Δ, after passing through a resistance, R, pass to the cups under O O′, so that for half an oscillation of the interruptor the current passes through the voltameter, which, during the other half oscillation, is short-circuited by way of the wires represented by dotted lines passing from the cups A A′ to B B′, which two latter are joined for half an oscillation by the thick wire B B′. This interruptor was worked by a small motor, and a registering mechanism was attached to count the number of times that the current passed through the voltameter. About 70 interruptions per minute were produced.

After 20,296 oscillations with a current of 0·171 amperes, the negative electrode was covered with a blackish film, the positive being quite bright. Since the blackening always takes place at the negative pole, it must be due to the action of the hydrogen. A difference of current density at the two electrodes has no effect on

* *Planté*, p. 10.

Digitized by Google

this blackening. The phenomena are obtained either with electrodes of equal surface or not, whether they are very small or not, and when the current density is below ·01 ampere per square centimetre.

No such result as we have above described occurs if the voltameter is not short circuited when the current through it is cut off. On using the apparatus shown diagrammatically in Fig. 4, after removing the wire between B and B′, both the platinum electrodes were found to be perfectly bright after 60,720 interruptions with a current of ·161 ampere. When the wire B B′ was replaced, 4,420 oscillations were sufficient to start the blackening of the surface.

This experiment makes it clear that, in order to reproduce this characteristic of platinum electrodes in electrolysing water by an alternating current, it is not necessary to make use of a direct current caused to alternate by means of a commutator, but it is sufficient if a polarisation, constant in sign but rapidly pulsating in magnitude, occurs at the negative electrode.

Rectification of Alternating Currents by Means of Electrolysis.

It may be easily shown that a voltameter with gold or platinum electrodes becomes polarised by the passage of an alternating current. If the electrodes have different areas the larger one behaves like the electrode surrounded by hydrogen in a gas battery. The polarisation or secondary current is of few moments. But if the voltameter receives a rapid series of charges with an alternating current, the discharges are all in the same direction, and, consequently, a true rectification of an alternating current is effected.

In order to show this I made use of a rotating contact-breaker (Fig. 5). Two wooden cylinders, A and D, were mounted on the

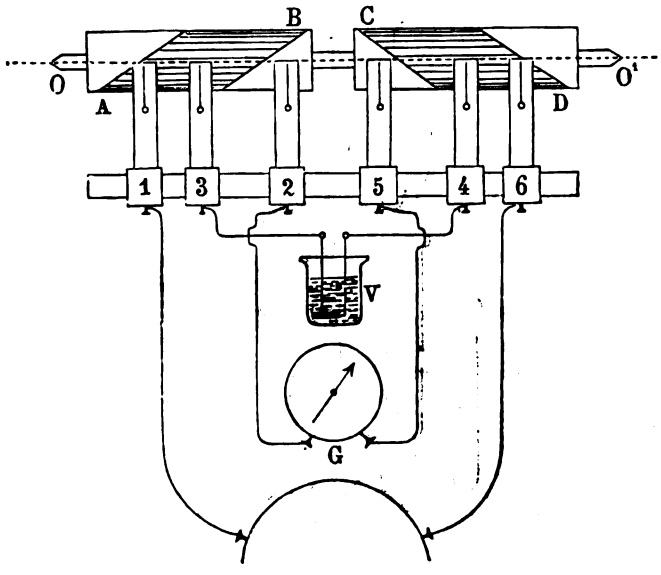

Fig. 5.

same spindle, and each was provided with a brass tube, A B C D, cut off helically at the extremities. The spindle, O O′, was rapidly rotated by means of a series of spur wheels and pinions. Six copper wire brushes, capable of sliding on a wooden rod, rubbed on the surfaces of the cylinders. During a rotation the brushes, 1, 2, 5 and 6, were in contact with the metal surfaces for a greater or smaller period of time, according to their position on the wooden rod; the brushes 3 and 4 were in permanent contact with the metal surfaces. Three distinct circuits were connected to these three pairs of brushes. An acidulated water voltameter was connected to 3 and 4, a reflecting galvanometer with its shunt to 2 and 5, and leads to the poles of an alternating current transformer to 1 and 6. With this arrangement, on rotating the spindle, O O′, at first an alternating current of short duration was sent through the voltameter, and then the current due to the polarisation set up was sent through the galvanometer, and the needle was deflected, but returned immediately to zero. If, however, the rotation was made sufficiently rapid it was found possible to find a speed at which the needle was permanently deflected.

Several different pairs of metals were examined, but the best results obtained were from the combination gold-platinum. The gold electrode had a surface of 300 square millimetres, and the platinum electrode 900 square millimetres. On rotating the communicator at a velocity of 5 to 10 revolutions per second, and placing the first and second pairs of brushes so that the voltameter was connected to the galvanometer for three-quarters of a revolution, and for less than one-quarter to the transformer, a direct current was obtained varying from 14·10 milliamperes to 47·00 milliamperes. The charging current could be varied from 0·5 to 3 amperes without obtaining any better result.

Conclusions.

(1.) In a voltameter traversed by an alternating current polarisation is set, varying periodically both in intensity and sign, in consequence of which the phase of the current is displaced behind that of the potential difference of the voltameter poles.

(2.) Electrolytic decomposition by means of an alternating current cannot take place unless the maximum value which can be reached by the polarisation during an alternation is equal to, or greater than, a certain definite limiting value depending on the natures of the electrolyte and the electrodes, and on the current density at each electrode.

In this case, during each alternation from the moment when the polarisation reaches this limit, electrolytic decomposition will occur, and will continue until the end of the alternation, that is, until the curve representing the current passes through the value zero. Thus, during each alternation there are two distinct periods: in the first, which lasts from the commencement of the current phase until the polarisation reaches the limiting value, decomposition will not take place; in the second, which occupies the remaining portion of the alternation, electrolysis proceeds regularly, and the quantity of the electrolyte decomposed will be proportional to the quantity of electricity which has passed through the voltameter in this interval. During successive alternations the same phenomena are repeated, so that at the end of any time it will be found that during a fraction only thereof has electrolysis been able to take place.

(3.) If we have two currents, one direct and the other alternating according to a sine curve, such that each conveys the same quantity of electricity through a voltameter in a given time, the quantity of the electrolyte decomposed by the former will be to that decomposed by the latter as the area corresponding to the duration of an alternation reckoned between two consecutive passages of the current through the zero value is to the area comprised in the interval of time during which electrolysis has been able to take place.

(4.) Diminishing the current density on one of the electrodes at which the products of electrolytic decomposition appear has the effect of diminishing the polarisation at this electrode. Consequently a point can be reached at which the polarisation during an alternation cannot reach the limiting value at which the products of decomposition can commence to appear; electrolysis will then cease to take place at this electrode.

If no electrolytic decomposition is seen to take place at one electrode of a voltameter traversed by an alternating current, increasing the current density will increase the polarisation so that it is possible to reach the above-mentioned limit, and then electrolysis will become visible at this electrode.

(5.) On increasing the rapidity of alternation of an alternating current, the strength and current density remaining constant, the polarisation on the same electrode in the same voltameter will continually decrease, so as to render it possible to bring it below the limit necessary for the products of electrolysis to be able to appear.

On the other hand, if, with a certain number of alternations, electrolysis is not obtained, diminishing the number of alternations will increase the polarisation so as to make it possible to reach the limit necessary for the products of decomposition to appear.

(6.) The energy consumed in a voltameter traversed by an alternating current is less than the product of the square root of the mean square of the current and the square root of the mean square of the potential difference at the voltameter poles. A voltameter traversed by an alternating current behaves like a metallic conductor possessing self-induction.

(7.) The ratio between the real and the apparent energy consumed in a voltameter traversed by an alternating current is nearer and nearer to one, the greater is the quantity of the electrolyte decomposed, the current density and number of alternations remaining constant.

If the same quantity of the electrolyte is decomposed by an alternating current as by a continuous current of equal quantity, the difference between the energies really and apparently consumed in a voltameter must be zero. The phases of the curves representing current and difference of potential at the voltameter poles would then be synchronous.

(8.) In a voltameter containing acidulated water, or a saline solution, the quantity of the electrolyte decomposed at an electrode by an alternating current (the current density at the electrode and the number of alternations remaining constant), increases if an obvious re-combination of the gases at the other electrode takes place. Owing to this re-combination, a direct current is superimposed on the alternating current, modifying its character.

In this way, with alternating currents, metallic deposits of copper, silver, nickel, &c., quite equal to those produced by direct currents can be obtained.

(9.) Alternating currents can effect the decomposition of fused salts, and this decomposition is subject to the current density law.

Digitized by Google

(10.) After a voltameter with gold or platinum electrodes has been traversed by an alternating current, a polarisation that will last some little time will be produced.

In general the electrode with the greater surface will act as the hydrogen electrode in a gas battery. The smaller electrode often presents a more intense polarisation, but of shorter duration.

(11.) By taking advantage of this polarisation, voltameters through which alternating currents pass can be used as a means of rectifying the same, transforming them into a series of direct currents of short duration, succeeding each other at brief intervals.

(12.) During electrolysis by alternating currents the electrodes are vigorously attacked and quickly destroyed.

Even platinum, gold, and iridium become covered with a powder, which increases, until it finally completely destroys the electrode.

THE EDISON ELECTRIC LIGHT COMPANY v. THE UNITED STATES ELECTRIC LIGHTING COMPANY.

DECISION OF JUDGE WALLACE IN THE U.S. CIRCUIT COURT, JULY 14, 1891.

We received yesterday from our New York contemporary, the *Electrical World*, of New York, the following full report of the judgment given in the above action. A Reuter's telegram of yesterday's date states that a suspension of the injunction has been granted for fifteen days pending an appeal :—

Two claims of letters patent, No. 223,898, granted Thomas A. Edison, January 27, 1880, for an improvement in electric lamps are in controversy in this suit. These are claims 1 and 2. It is not asserted for plaintiff that the defendant infringes the other claims of the patent, consequently they will require no attention further than to see whether their terms may assist in defining the meaning of the claims in litigation.

The plaintiff contends that these claims are for fundamental inventions of great merit, and are entitled to a construction by which every incandescent lamp for electric lighting, consisting essentially of a filamentary carbon burner, hermetically sealed in a glass vacuum chamber, is within their terms. The defendant contends that unless the claims are limited to narrow inventions, not employed by the defendant, they are invalid for want of patentable novelty. The questions of the validity and scope of the patent have been adjusted in the Courts of England and Germany with a diversity of opinion by the judges who have considered them. The specification is a perplexing one. The difficulty lies in its shadowy demarcation of the line between the essential and non-essential feature of the invention described. It catalogues a number of discoveries which Mr. Edison had made ; it sets forth some of the essential features of the lamp, and then it leaves to be found by inference from generalities what the elements are of the combinations included in the extremely elastic terms of the two important claims.

Nevertheless, when a sufficient knowledge of the prior state of the art to which it relates has been acquired, the new departures from the old devices which it describes, and which, presumably, the inventor proposed to incorporate into the claims of his patent, are reasonably apparent. The specification states that the object of the invention is "to produce electric lamps giving light by incandescence, which lamps shall have a high resistance so as to allow of practical subdivision of the electric current into numerous small units and their conversion into luminous centres." By practical subdivision is meant a distribution and division of the current and its conversion into lights comparable with those of ordinary gas jets, on a scale and under conditions of convenience and economy adequate to a system of illumination for domestic purposes in villages and cities analogous to that of gas. Prior to 1879 there was no method known by which this could be done practicably. The problem involved the perfection of devices for the proper distribution and regulation of the current, as well as those for translating it into the light. No reference to the pre-existing devices for generating electricity, conducting it to the translating devices, or regulating its pressure and quantity, is necessary except to state that the principles governing the relation of the resistance of translating devices to the character of the circuit in which they are arranged, whether in series or in multiple arc, were well known to electricians, and had been applied in various forms of electrical apparatus. There were two well-known devices for converting the current into light—the arc lamp and the incandescent lamp. In the former the current is forced to leap an air gap separating two conductors, usually of carbon, and in overcoming the resistance of the air space heats the adjacent surfaces of the conductors and produces a light of great intensity. In the latter light is produced by the incandescence of an electrical conductor, a conducting strip of burner, placed in a continuous circuit through which the current passes and which develops heat by its resistance to the flow. The arc lamp was suitable for use in streets, open spaces and large halls, but its light was too concentrated and powerful for the illumination of dwellings or of rooms of small dimensions. It was the generally accepted opinion of electricians that the hope of progress in the subdivision of the electric light was to be found in modifying the features of the arc lamp. The reason for this conclusion need not be mentioned ; it suffices to say that Mr. Lane-Fox in England, and Mr. Edison in this country, seem to have been the only notable dissidents, and each of them had expressed the conclusion that subdivision might be accomplished by the incandescent lamp when provided with a conductor of high resistance and small radiating surface arranged in system of multiple arc. Lane-Fox had set forth the advantages of such a lamp in three patents granted to him in England, and two in October, 1878, and one in March, 1879, and in a letter to the London *Times*, published in December, 1878 ; and Mr. Edison had done so in a patent granted to him in France, May 28, 1879, for improvements in electric lighting.

By arrangement in multiple arc no greater electromotive force is required for a large number of translating devices than for a single one, and the amount of current can be graduated to the number employed ; consequently, a lamp with a conductor of high resistance can be utilised as efficiently as one with a conductor of low resistance. Higher resistance in the conductor permits the use of a weaker current, and, consequently, of smaller and less expensive main conductors. With a small surface of conductor less energy is required to produce a candle power, and the small incandescent mass will radiate a moderate light, like the domestic lamp. Electricians knew how to make conductors of high resistance, and how to make them with a small radiating surface. They knew that with the materials of the same specific resistance the total resistance of the conductor could be varied by varying its length and cross section. They knew what materials were preferable and what processes of treatment to make conductors of high or low resistance.

If they had only known how to construct a lamp in which the conductor would have adequate mechanical strength and durability for practical commercial use, while having the small radiating surface and high resistance desirable, there would have been nothing wanting, and electric lighting by incandescence would soon have been an accomplished fact. Although Lane-Fox and Edison had contributed to the state of the art the recognition of the principle that the conductor must have high resistance and small radiating surface, and each of them had embodied the principle in lamps, for which they had severally obtained patents, neither of them had invented a lamp which satisfactorily embodied all the conditions of success because a burner of the necessary material, form, and complementary adjuncts was yet to be devised. As to material, experiments had been tried with platinum, iridium, and alloys of these metals, and with carbon of various kinds. It was known that platinum, being a poor conductor, could be readily brought to incandescence by the electric current, but to do so it was necessary to raise it to a temperature very near the fusing point, and a minute increase would melt it. On the other hand, carbon was known to possess at an equal temperature much greater power of radiation than platinum, but the difficulty was that it would combine with oxygen at high temperature and rapidly disintegrate. It could only be used, therefore, in a vacuum which was practically unattainable. From the earliest lamp (disregarding the Geisler tube, because it has no burner in the true sense), patented in England by King in 1849, to the latest examples, like those of Lane-Fox or Edison's platinum lamp, patented in 1878-9, the history of the art shows a variety of experiments to perfect a lamp in which a carbon burner or a platinum burner would have sufficiently long life for practical requirements. The result of these experiments may be succinctly shown by quoting two well-known electricians. Mr. Schwendler, in an article published in 1879 in the *Telegraphic Journal*, said : "Unless we shall be fortunate enough to discover a conductor of electricity with a much higher melting point than platinum, and the specific weight and specific heat of which conductor is also much lower than for platinum, and which at the same time does not combine at high temperatures with oxygen, we can scarcely expect that the principle of incandescence will be made use of for practical illumination." Mr. Sawyer, in a patent to Sawyer and Man, granted in June, 1878, said : "At the present day it is not new to produce a light by causing the electric current to heat a carbon conductor to incandescence in a vacuum, or in nitrogen, or in other gas ; but no lamp has yet been devised which would be practically operative, and for these reasons : First, the methods which have been adopted for charging the lamp with the artificial atmosphere, such as a displacement of mercury, water, or air by the gas, or the combustion of phosphorus in the lamp, are imperfect. A perfect vacuum is unattainable. Some oxygen or other element or compound remains in the lamp, and slow consumption or disintegration takes place, for the remaining gas or vapour other than hydrogen or nitroge attacks the carbon, which, in turn, is decomposed, with a result of depositing some carbon upon the globe and setting free the oxygen to attack fresh carbon. Second, it has been found practically impossible under the varying degrees of heat and pressure to maintain perfect joints, and the result is that expansion of the artificial atmosphere by the heat from the luminous conductor expels a portion of the same, and the contraction of the atmosphere, upon cooling, causes a portion of the external air to penetrate the globe, thus supplying oxygen, which at the least lighting feeds upon the carbon. Third, the unequal expansion of the carbon and its holders has resulted in fractures of the former, so that, however perfect the atmosphere in the globe, the lamp has never been permanent."

The most advanced type of carbon burner lamps in 1875 were the lamps of Lodyguine or of Konn, and until the spring of 1879 lamps like those of the Sawyer and Man patent or the patents of Mr. Farmer. It was thought to be the merit of Lodyguine's lamp that it obviated the difficulty of the short life of the burner by using two burners, rods of diminished section at the luminous focus, on a glass receiver. hermetically sealed and filled with nitrogen, electrically arranged so that the current would be passed to the second carbon when the first had been consumed. Konn provided his lamp with five carbon burners, in the form of rods or pencils, and devices for bringing them successively into circuit. In the lamp of Sawyer and Man the carbon burner was a rod or pencil maintained in a globe, and its stopper (both of glass) was held together by a clamping device. In the lamp of the patents granted to Mr. Farmer in March, 1879, the burner was a carbon rod or pencil, enclosed in a globe filled with hydrogen or other analogous gas, and the globe was closed by a rubber stopper. In none of the lamps, except the

Digitized by Google

one described in Mr. Edison's prior French and English patents of 1879, had any attempt been made to make the vacuum chamber wholly of glass, with the parts sealed together by fusion, or to seal the conducting wires leading to the burner, through the glass by fusion of the glass. The impracticability of maintaining a carbon burner under such conditions that it would be sufficiently durable, has, apparently, so impressed those who were studying lighting by incandescence that, as late as in the early part of 1879, both Lane-Fox and Edison were trying to perfect a burner of other material. Edison's burner in his French patent of May 28, 1879, was of platinum wire coiled upon a bobbin, composed of an infusible oxide, and Lane-Fox's burner in his patent, of May 14, 1879, was of platinum-iridium alloy, or of spiral strips of metal, surrounding a tube of glass, fire-clay, steatite, or lime, with the surface of the metal strips covered with asbestos or some vitreous material.

This cursory view of the prior state of the art is sufficient for an intelligent reading of the specification. The specification describes the general nature of the invention as follows:—

"The invention consists in a light-giving body of carbon wire or sheets coiled or arranged in such a manner as to offer great resistance to the passage of the electric current, and at the same time present but a slight surface from which radiation can take place.

"The invention further consists in placing such burner of great resistance in a nearly perfect vacuum, to prevent oxidation and injury to the conductor by the atmosphere. The current is conducted into the vacuum bulb through platina wires sealed into the glass.

"The invention further consists in the method of manufacturing carbon conductors of high resistance, so as to be suitable for giving light by incandescence, and in the manner of securing perfect contact between the metallic conductors or leading wires and the carbon conductors."

The specification then recites that previously light by incandescence has been obtained from rods of carbon of one to four ohms resistance, placed in closed vessels in which the atmospheric air had been replaced by gases that did not combine chemically with the carbon; that the vessels holding the burner had been composed of glass cemented to a metal base; that the connection between the leading wires and the carbon had been obtained by clamping the carbon to the metal; that the leading wires have always been large, so that their resistance should be many times less than the burner, and, generally, the attempts of previous persons had been to reduce the resistance of a carbon rod. It then points out the disadvantages of such a lamp, stating that it could not be worked in great numbers in multiple arc without the employment of main conductors of enormous dimensions; that, owing to the low resistance, the leading wires have to be of large dimensions and good conductors, and a glass globe cannot be kept tight at the place where the wires pass in, and are cemented, and consequently the carbon is consumed, because there must be almost a perfect vacuum to render it stable, especially when it is small in mass and high in electrical resistance; and that the use of gas in the receiver at the atmospheric pressure serves to destroy the carbon by attrition.

The specification then states, in substance, that the patentee proposes a new departure; that he has discovered that even a cotton thread, properly carbonised and placed in a sealed glass bulb exhausted to one-millionth of an atmosphere, offers from 100 to 500 ohms resistance to the passage of the current, and that it is absolutely stable at very high temperatures; that if the thread be coiled as a spiral and carbonised, or if a fibrous vegetable which will leave a carbon resistance after heating in a closed chamber be so coiled, as much as 2,000 ohms resistance may be obtained without presenting a radiating surface greater than three-sixteenths of an inch; that if such fibrous material be rubbed with a plastic compound of lampblack and tar its resistance may be made high or low, according to the amount of lampblack placed upon it; that carbon filaments may be made by a combination of tar and lampblack, the latter being previously ignited in a closed crucible for several hours, and afterwards moistened and kneaded until it assumes the consistency of thick putty; that small pieces of this material may be rolled out in the form of wire as small as seven one-thousandths of an inch in diameter and over a foot in length, and the same may be coated with a non-conducting, non-carbonising substance and wound on a bobbin, or as a spiral, and the tar carbonised in a closed chamber by subjecting it to high heat, the spiral after carbonisation retaining its form; that he has carbonised and used cotton and linen thread, and splints, papers, coned in various ways, also lampblack, plumbago, and carbon in various forms, mixed with tar and kneaded so that the same may be rolled out into wires of various lengths and diameters; that each wire should be uniform in size throughout; and all those forms are fragile, and cannot be clamped to the leading-in wires with sufficient force to ensure good contact and prevent heating; that if platinum wires are used, and the plastic lampblack and tar material be moulded around it in the act of carbonisation, there is an intimate union by combination and by pressure between the carbon and platinum, and nearly perfect contact is obtained without the necessity of clamps; that the burner and leading wires should be connected to the carbon ready to be placed in the vacuum bulb, and when fibrous material is used the plastic lampblack and tar should be used to secure it to the platina before carbonising.

The specification proceeds as follows:—

"By using the carbon wire of such high resistance I am enabled to use fine platinum wires for leading wires, as they will have a small resistance compared to the burner, and hence will not heat and crack the sealed vacuum bulb. Platina can only be used, as its expansion is nearly the same as that of glass.

"By using a considerable length of carbon wire and coiling it, the exterior, which is only a small portion of its entire surface, will form the principal radiating surface; hence I am able to raise the specific heat of the whole of the carbon, and thus prevent the rapid reception and disappearance of the light, which on a plain wire is prejudicial, as it shows the least unsteadiness of the current by the flickering of the light, and if the current is steady the defect does not show."

The specification then gives directions for carbonising the carbon thread in a manner to prevent its distortion, for blowing a glass bulb over it after it is formed, for exhausting the glass bulb, and for hermetically sealing the bulb when a high vacuum has been reached.

The claims are as follows:—

"1. An electric lamp for giving light by incandescence, consisting of a filament of carbon of high resistance, made as described, and secured to metallic wires as set forth.

"2. The combination of carbon filaments with a receiver made entirely of glass and conductors passing through the glass, and from which receiver the air is exhausted, for the purpose set forth.

"3. A carbon filament or strip coiled and connected to electric conductors so that only a portion of the surface of such carbon conductors shall be exposed for radiating light, as set forth.

"4. The method herein described of securing the platina contact-wires to the carbon filament, and carbonising of the whole in a closed chamber, substantially as set forth."

The specification is addressed to those who were skilled in the art to which it relates; who appreciated the advantages of arranging incandescent lamps in a system of multiple arc, and of providing the lamp with a burner of high resistance and small radiating surface; who knew how high resistance, both specific and total, is imparted to a conductor; who knew that the rods, pencils, or other forms of carbon burners previously used had not been designed to embody the principle of high resistance; who knew how desirable it was to maintain the burner in a perfect vacuum, or in gases that would exclude the oxygen; who knew what had been attempted and had proved impracticable in that behalf; who knew that such materials as are mentioned in the specification (even the tar-putty compound seems to have been used in one process) would compose a carbon of high resistance when subjected to a proper process of carbonisation; and who knew how to practise proper processes for the carbonisation of such materials.

Read by those having this knowledge, the radically new discovery disclosed by the specification is that a carbon filament as attenuated before carbonisation as a linen or cotton thread, or a wire seven one-thousandths of an inch in diameter, and still more attenuated after carbonisation, can be made which will have extremely high resistance and be absolutely stable when maintained in a practically perfect vacuum. It informs them of everything necessary to utilise this discovery and incorporate it in a practical lamp. It describes, with the assistance of the recital in the second claim, as the vacuum in which the burner is to be maintained, a bulb made wholly of glass, exhausted of air, sealed at all points by the fusion of the glass, and in which platinum leading wires are sealed by the fusion of the glass. It describes the materials of which the burner is to be made, and instructs them that the materials are to be shaped into their ultimate form before carbonisation. It describes the use of platinum for leading wires, and a method of securing the leading wires and filaments, intended to dispense with clamping, which consists in moulding tar-putty about the joints, and carbonising the whole in a closed chamber. Besides stating that the resistance of the burner will be greatly increased, and the radiating surface still be kept within moderate limits, by coiling it in the form of a spiral, the specification states that, by increasing the lengths of the filament coiled, the exterior only will be the principal radiating surface, and greater steadiness of illumination will be promoted.

The first claim must be read with several limitations. The filament is to be made of carbon of high resistance; that is, as the experts agree, of high specific resistance. The filament is to be made as described; that is, the materials are to be of some of the kinds described, and are to be shaped in filamentary form, and then carbonised. The filament is to be secured to metallic wires according to the method of the patent, because the claim implies the elements of a globe and metallic conductor arranged in circuit with the burner, otherwise the combination would not be operative, and it would have been needless to specify the securing of the metallic wires to the filament unless it was intended to insert into the claim the specific method of doing so emphasised in the specification.

The defendant does not infringe this claim, if for no other reason, because the leading wires in its lamps are not secured to the filament according to the method of the patent, that is, by cement carbonised *in situ*, by clamps such as the specification condemns.

The second claim is broad enough in its phraseology to secure the real invention described in the specification, and can be read consistently with its language so as to impart into it every essential limitation.

It was a remarkable discovery that an attenuated thread of carbon would possess all the long-sought qualities of a practical burner when maintained in a perfect vacuum. The extreme fragility of such a structure was calculated to discourage experimentation with it, and it does not detract in the least from the originality of the conception that previous patents had suggested that thin plates, or pencils, or small bridges could be used. The futility of hoping to maintain a burner in vacuo with any permanency had discouraged prior inventors, but Mr. Edison is entitled to the credit of obviating the mechanical difficulties which disheartened them, but what he did in this respect was a matter of only secondary merit, and was no longer new in the art because he had already disclosed it in his French and English patents. What he actually accomplished was to unite the characteristics of high resistance, small radiating surface, and durability in a carbon conductor by making it in a form of extreme tenuity, out of any such materials as are mentioned in the specification, carbonising it, and arranging it, as he had previously arranged his platinum burner, in an exhausted bulb made wholly of glass and sealed at all points, including those where the leading wires entered, by the fusion of the glass. He was the first to make a carbon of materials

Digitized by Google

and by a process which was especially designed to impart high specific resistance to it; the first to make a carbon in the special form for the special purpose of imparting to it high total resistance; and the first to combine such a burner with the necessary adjuncts of lamp construction to prevent its disintegration and give it sufficiently long life. By doing those things he made a lamp which was practically operative and successful, the embryo of the best lamps now in commercial use, and but for which the subdivision of the electric light by incandescence would still be nothing but the *ignis fatuus* which it was proclaimed to be in 1879 by some of the learned experts who are now witnesses to belittle his achievement and show that it did not rise to the dignity of an invention.

The coiled form of the burner is only an alternative feature, and is not a constituent of the second claim. It is the subject of the third claim. Nor is the bent form or any form other than the filamentary. It may be that in the haste, which has always seemed to characterise Mr. Edison's efforts to patent every improvement, real or imaginary, which he has made or hoped to make, he had not stopped to reflect when he framed his application for the patent that the filamentary burner would do its work just as well uncoiled as coiled, provided the same length and cross-section were used. It is true that it is said in the general statement of the nature of the invention that the burner is so "coiled or arranged" as to offer high resistance and present a small radiating surface; but this description is satisfied by any arrangement, whether by coiling a considerable length in a small globe or using the same length uncoiled in a large globe, by which sufficient total resistance is obtained from a filament of small diameter. It certainly would not involve invention to omit the coiling and elongate the globe; hence, it is manifest that the invention described is the same thing essentially, whether the coiled form is used or not. The language is satisfied if the burner is filamentary, and so arranged as to offer great resistance and slight radiation, without importing into it anything which is not of the essence of the invention. No precise limitation upon the maximum diameter of the filament can be defined from the specification, or is required as an element of the claim. The specification mentions, by way of illustration, the threads of linen or cotton which become more attenuated after carbonisation, and the carbon wire which, after carbonisation, would be from four to five one-thousandths of an inch in diameter, while the smallest rods of carbon previously known were about a millimetre in diameter, thus having a cross-section fifty times as great as the carbon wires. It is to be implied from the suggestions in the specification that it is to have sufficiently high total resistance for efficient use when the lamps are arranged in multiple arc, and to be used with leading wires of fine platinum. The claim is not limited to a carbon filament made of non-fibrous material. The conductors of the claim are the platinum wires mentioned in the specification. The receiver is the vacuum described in the specification. The peculiar method of securing the conductors to the filament, made a constituent of the first claim, is not imported into the second claim. A more exact interpretation of the meaning of the claim than has thus been indicated is not necessary in the present case, because each of the three lamps representing the kinds used by the defendant embodies the invention of the claim as thus interpreted.

It is of little import what Mr. Edison or his patent solicitor may have thought about the meaning of the claim during the pendency of the application for a subsequent patent, or that Mr. Edison may have supposed a resistance as high as 100 ohms in the burner would be required for use with the means of distribution which he expected to employ with his system of lighting. There are many adjudicated cases in which it appears that the inventor builded better than he knew; where a patent has been sustained for an invention the full significance of which was not appreciated by the inventor when it was made. In the case of the Bell telephone patent there was great room for doubt whether the speaking telephone had been thought of by Mr. Bell when he filed his application for a patent, but the Court said: "It describes apparatus which was an articulating telephone, whether Bell knew it or not." 88 Blatch., 532.

The nearest approach in the prior art to the invention of the second claim is undoubtedly the lamp of Edison's French and English patents with a platinum burner. It seems almost preposterous to argue that the substitution of a carbon filament for the platinum burner of that lamp was an obvious thing to electricians. It would have been, probably, if there had been such a thing as a filamentary carbon in the prior art. But the nearest approximations to it were the ribbon-shaped carbon burner of low resistance of Mr. Farmer (which was not a part of the prior art, but an isolated example known only to a select few), and the low resistance carbon rod burners of the patent of Sawyer and Man.

Undoubtedly the improvements that have been made in the art—such, for instance, as the method of electrical carbonisation of the filament—since Mr. Edison's invention, have been of great value, and the perfected commercial lamp of to-day is far superior to the one which could be made by applying to the description of the patent all the knowledge and skill then possessed by those to whom it was more particularly addressed. But, as was said by Bowen, L.J., in the Court of Appeals in England, "the evidence shows that lamps made solely on the patent will and do succeed, although subsequent improvements have been ingrafted on the original design." It is impossible to resist the conclusion that the invention of the slender thread or carbon as a substitute for the burners previously opened the path to the practical subdivision of the electric light.

The questions which have seemed the most meritorious of those argued at the bar have now been considered. Others, to which no reference has been made, have not been overlooked, and may be dismissed without discussion, and with the single remark that nothing which has been presented by the voluminous proofs and the exceedingly able and elaborate arguments of counsel seems to supply any valid reason for refusing to decree for the plaintiff.

The usual decree for an injunction and accounting is accordingly ordered.

ELECTRIC LIGHTING AT BRADFORD.

At the meeting of the Bradford Town Council, last week, Alderman F. PRIESTMAN, Chairman of the Gas and Electricity Supply Committee, on moving the adoption of the minutes, said that with regard to the electric lighting works, the present works had cost £35,000, and he was going to ask for £5,000 or £6,000 for increasing those works. It was proposed to put down one 300 H.P. engine, and two 80 H.P. engines. The works now were able to supply 3,500 amperes, and with this addition would produce 1,800 more. The proposal to light the Town Hall was before the Council, and would probably soon be carried out, and the Committee had a large number of demands for the electric light current. They had not pressed the matter, for they had the interests of the gasworks—in which a large amount of capital had been sunk—to preserve, but the increased demand was consequent upon the superiority of the electric light. He apprehended that the Council would wish that the Committee should keep pace with these demands.

Mr. J. GALLOWAY thought the Chairman of the Gas and Electricity Supply Committee ought not to have used the word "economy" in his remarks, because the electric light had been a source of loss to the Corporation. If the supplying of the electric light was a paying concern he would support Alderman Priestman, but he could not do so at present.

Alderman SMITH FEATHER appealed to the Chairman of the Gas and Electricity Supply Committee to postpone the proposed addition. He understood that they were at present consuming 6lb. of coal per hour for each horse-power indicated, and he had been informed that the consumption could be reduced to 1½lb. per hour. He was further given to understand that a proposal had been made to the Halifax Corporation to supply a complete electric plant and guarantee a profit of 7½ per cent.; and if that could be done at Halifax it could be done in Bradford.

Alderman PRIESTMAN, in reply to Mr. Galloway, said he considered the expenditure on the electric light works was a wise one. He would not propose any expenditure of public money unless he believed it would be a wise expenditure. Up to December 31, 1889, the loss on the electric lighting works was £1,079; during the half year ended June 30, 1890, the loss was £732; and from that date to December 30, 1890, the loss was £315. That showed clearly that they were now on the verge of making the works pay, and, from the facts and figures he had given to the Council, he had not the slightest hesitation in saying that by the end of next year those works would be paying more than the interest on the money expended on them. He appealed to the Council to complete the installation in the way proposed by the Committee. He believed that it would very soon be the duty of some one to ask the Council to spend an additional sum of money on the electric light works, and that would be the best time to deal with the question raised by Alderman Feather. He thought the Committee was proceeding in the most economical course possible. There had been a complaint in some quarters about the Committee not adopting the alternating current, and in answer to that complaint he wished to state that the direct and continuous current was the one most favoured by authorities on the subject, and was the one which would probably be generally adopted in the future.

The resolution was carried.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.—SELECT COMMITTEE.

On Thursday, last week, the St. Luke (Chelsea) Electric Lighting Provisional Order Bill again came before the Select Committee of the House of Lords, presided over by Lord Basing, it having been reconstructed in order that the petition of the London County Council against the amendments introduced into the Bill by their Lordships, at the instance of the Vestry of Chelsea, might be considered.

Mr. Cripps, Q.C., appeared on behalf of the London County Council, in support of the petition, while Mr. Holland, clerk to the Vestry of Chelsea, opposed it.

Mr. CRIPPS, in opening the case for the petitioners, said subsequently to the passing of the Electric Lighting Act, 1888, the Board of Trade wrote to the London County Council that they were anxious to take no definite steps which would have an important bearing on the future policy to be pursued with regard to electric lighting without communicating with the Council, and that they were unwilling to take any action which might hamper them in the future. The result was that nearly the entire area of the County of London had been appropriated for electric lighting purposes to one or more electric lighting companies, and that all these Provisional Orders had followed a "model form" which had been adopted, after much discussion, by the Board of Trade, and generally accepted by the local authorities, so that the law as to electric lighting was in the same form throughout the whole of the County of London. The provisions in force throughout the County of London, as regarded the inspection and testing of electric lines and meters, were regarded by the Council as of exceptional importance. The County

Digitized by Google

of London was divided into about forty different parishes, and great confusion and difficulty would result if the laws as regarded the inspection of electric lines and meters differed in various parishes, and were administered by different authorities. The County Council had, under their Acts now in force relating to electric lighting, provided a staff and appliances for the purpose of testing electric lines, and a station for the purpose of testing meters, and he submitted that it was not only important that the provisions with respect thereto should be uniform throughout the county, but that the whole system could be worked more economically and efficiently by means of the establishment of the County Council, as the central authority representing London, than by the various parochial authorities in their own areas. It had been urged that there was in existence as regarded part of the parish of Chelsea a Provisional Order, passed in 1886, under which the Vestry of Chelsea had powers with regard to the appointment of an inspector. He would, however, point out that this Order was passed prior to the creation of the London County Council, and to the passing of the Electric Lighting Act, 1888. He maintained that it was important in regard to this matter that the legislation throughout London should be uniform. The petition of the Vestry of Chelsea appeared to have been based upon a misapprehension. He asked their Lordships to restore the Order to the form settled by the Private Bill Committee presided over by Sir G. Trevelyan.

The CHAIRMAN asked whether it was a fact that, with the exception of the parish of St. Luke, Chelsea, all the operative electric lighting orders in London had been passed since 1888.

Mr. CRIPPS said he believed that every one of them had been passed since 1888.

The CHAIRMAN said the County Council could not deprive the Chelsea Vestry of the powers they possessed under the Act of 1886.

Mr. COURTENAY BOYLE, of the Board of Trade, gave evidence in support of the case for the County Council.

The CHAIRMAN said there was no intention of casting any reflection upon the policy which the Board of Trade had adopted since 1888. The Committee thought that the case of Chelsea was peculiar, and required different treatment.

The Committee, after a short consultation, said they did not desire to hear Mr. Holland on behalf of the Chelsea Vestry. Lord Basing remarked that the Committee had come to the conclusion that the alterations made on the last occasion at the instance of the Vestry must be supported. They, however, desired him to say that they had no wish whatever to call in question the wisdom of the policy of the Board of Trade since 1888. They refused the petition of the County Council, because they believed that the amendments of the Vestry would create less confusion.

The Bill was then ordered to be reported to the House.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 11, 1891.

Electric Traction in Brooklyn.—The electric railway has scored one considerable point in its struggle for admission in the vicinity of New York. The Railroad Commissioners have granted the request, in spite of numerous protests, of one of the Brooklyn railway companies to change its motive power to electricity. The case has been under discussion for some time, and it is only recently that this decision was reached. Undoubtedly further legal measures will be taken to prevent the erection of the overhead lines, but probably without much success.

The New York Rapid Transit Commission.—Very little has been heard of late about the proceedings of the Rapid Transit Commission. Borings have been going on through the lower part of the city with the idea of determining the depth and character of the substratum of rock that will have to be encountered in the carrying out of any tunnelling scheme; and they reveal the fact that a tunnel will not be specially difficult to construct. Meanwhile the building of the cable conduit on Broadway is progressing rapidly, especially in the upper part of the city. The Broadway line obtained permission to change its motive power to cable some time since, although the work has been much delayed, and there were rumours that it would not be carried out at all. Work is now going on with considerable rapidity, and the date named for beginning operations with the new motive power is October 1st. It is very doubtful, however, if the necessary equipment will be completed by that time.

Proposed Electrical Trust.—There is considerable discussion just now about the formation of an electrical trust not dealing in apparatus but in general electrical supplies. With all the conflicting interests at stake, it is very doubtful if any definite and permanent arrangement could be entered into, and present appearances indicate that the affair will settle down into a combination of three or four important houses in this part of the country with a view of controlling a certain portion of the supply trade. The competition in this line has been very severe, and two electrical companies of that sort have collapsed within the past few days.

CORRESPONDENCE.

EXPERIMENTS ON THE ELECTRIC DISCHARGE IN VACUUM TUBES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In *The Electrician* for July 17th there is a description of some experiments made by Mr. Nikola Tesla, which are somewhat similar in character to those shown by me to the Cambridge Philosophical Society, in February, and to the London Physical Society, on their visit to Cambridge, on May 9th. Mr. Tesla seems to ascribe the effects he observed to electrostatic action, and I have no doubt, from the description he gives of his method of conducting his experiments, that in them electrostatic action plays a very important part. He seems, however, to have misunderstood my position, with respect to the cause of these discharges, which is not, as he implies, that luminosity in tubes without electrodes cannot be produced by electrostatic action, but that it can also be produced when this action is excluded. As a matter of fact, it is very much easier to get the luminosity when these electrostatic effects are operative than when they are not. As an illustration of this I may mention that the first experiment I tried with the discharge of a Leyden jar produced luminosity in the tube, but it was not until after six weeks' continuous experimenting that I was able to get a discharge in the exhausted tube which I was satisfied was due to what is ordinarily called electro-dynamic action. It is advisable to have a clear idea of what we mean by electrostatic action. If, previous to the discharge of the jar, the primary coil is raised to a high potential, it will induce over the glass of the tube a distribution of electricity. When the potential of the primary suddenly falls, this electrification will re-distribute itself, and may pass through the rarefied gas and produce luminosity in doing so. Whilst the discharge of the jar is going on it is difficult, and, from a theoretical point of view, undesirable to separate the effect into two parts, one of which is called electrostatic, the other electro-magnetic; what we can prove is that in this case the discharge is not such as would be produced by electromotive forces derived from a potential function. In my experiments the primary coil was connected to earth, and, as a further precaution, the primary was separated from the discharge tube by a screen of blotting paper, moistened with dilute sulphuric acid and connected to earth. Wet blotting paper is a sufficiently good conductor to screen off a stationary electrostatic effect, though it is not a good enough one to stop waves of alternating electromotive intensity. When showing the experiments to the Physical Society I could not, of course, keep the tubes covered up, but, unless my memory deceives me, I stated the precautions which had been taken against the electrostatic effect. To correct misapprehension I may say that I did not read a formal Paper to the Society, my object being to exhibit a few of the most typical experiments. The account of the experiments in *The Electrician* was from a reporter's note, and was not written or even read by me. I have now almost finished writing out, and hope very shortly to publish, an account of these and a large number of allied experiments, including some analogous to those mentioned by Mr. Tesla on the effect of conductors placed near the discharge tube, which I find, in some cases, to produce a diminution, in others an increase, in the brightness of the discharge, as well as some on the effect of the presence of substances of large specific inductive capacity. These seem to me to admit of a satisfactory explanation, for which, however, I must refer to my Paper. I am glad to be able to take this opportunity of mentioning that I

Digitized by Google

find that the luminosity produced in a vacuum tube placed near a wire through which a Leyden jar is discharged, was noticed by Hittorf, and described by him in *Weidemann's Annalen*, Vol. XXI., p. 138. As, however, the discharge filled his tube, and did not pass as a ring, I should imagine that the cause of the discharge was primarily electrostatic.—I am, Sir, &c. J. J. THOMSON.

Cambridge, July 18, 1891.

SWIVEL BEARINGS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the Editorial Notes of your issue of 17th you comment on the "egg in the napkin ring" form of self-lining bearing. Premising that the object of this arrangement is quite as much to obviate twist in the bed-plate as bending of the shaft, I should like to offer a few comments. The design is, as you say, "hideous as an expedient," and in my own observation the result is what would be expected. Whether the form of bearing gives trouble is a matter of comparative statement, but that the arrangement is unmechanical is certain, and in practice the seating round the bush wears seriously, and I know of several cases where the bushes have had to be taken out and turned over to bring fresh portions of the line of contact into action. I have seen this result, both in the dockyards with dynamos used by the services, and in central stations. It is for this reason that in the steam dynamos made by Messrs. W. T. Goolden and Co., true spherical-seated bearings have been adopted with most excellent results. The brush has a spherical centre, seated on a spherical bed cast in hard white metal, fitting the sphere all over. After two years' heavy wear I have failed to detect any deterioration in such bearings.—Yours, &c.,

LLEWELLYN B. ATKINSON.

Woodfield Works, Harrow-road, W.

TRADE NOTES AND NCTICES.

TENDERS ACCEPTED.—The London County Council have accepted the renewed tender of Messrs. H. Binko and Co. for maintaining for three years the electrical installations in connection with the Metropolitan Fire Brigade, for £123. 15s. The firm will also fit up any new installations which may be required, at a schedule of prices agreed upon. The other tenders were—R. Colston, £175; Julius Sax, £395; Pyke and Harris, £500.

ANNUAL DINNERS.—The annual dinner of the *employés* of Messrs. D. Hulett and Co. took place on Saturday last, at Markwell's Hotel, Brighton, the party numbering 86.

——— The *employés* of Messrs. Poole and White (Limited) held their annual dinner on Saturday last, at Taplow, Berkshire, the party numbering nearly 50. An interesting feature of the day's proceedings was the sports.

——— The *employés* of the Fowler-Waring Cables Company held their second annual excursion on Saturday last at Ightham, Kent. More than 100 sat down to dinner; and amongst the sports indulged in was a cricket match, in which Mr. George Neill's eleven were victorious.

ALTERATIONS OF ADDRESS.—The Pilsen Electric Company have removed their offices and works from 4, Stanhope-street, Euston-road, N.W., to more central and extensive premises at 80, Leather-lane, E.C., which are being specially arranged for the manufacture of Pilsen arc lamps and all accessories for electric lighting and transmission of power. We are informed that the Company are preparing for the market several new forms and adaptations of the Pilsen lamp, and also an improved kind of arc light carbon.

——— Mr. A. F. Spooner informs us that he has removed his patents, designs, and trade marks agency to 124, Chancery-lane, London, W.C.

AMERICAN COAL CUTTERS.—Messrs. Shippey Brothers inform us that they are introducing a new electric coal cutter, and announce that they are prepared to sell the machines outright, free from royalty, or contract with colliery owners to cut the coal at a fixed price per ton.

ELECTRICAL PLANT AT THE GOLDSMITHS' INSTITUTE, NEW CROSS.—The latest and most improved appliances have been provided for ventilating this Institution by Messrs. Easton and Anderson, who have put down one of their improved electro-motors, driving direct on to a Blackman fan, for supplying the necessary fresh air to the lecture halls. A "Whitehall" dynamo, Prentice's patent, is placed in the space adjoining the electrical laboratory and supplies current to the electro-motor. It has also been proposed to work the bellows of the grand organ, shortly to be erected, by electro-motors, controlled by the organist with magnetic clutches. In this way a large volume of air can be obtained at the will of the player. The "Whitehall" dynamos are driven by the steam engine used for pumping and other purposes, and this will prove an interesting example of how the power may be electrically distributed for a variety of purposes through a large building.

COMPANIES' MEETINGS & REPORTS.

The Eastern Telegraph Company (Limited).

The thirty-eighth half-yearly ordinary general meeting of the Eastern Telegraph Company (Limited) was held at Winchester House, Old Broad-street, on Thursday, July 16, 1891, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. George Draper) having read the notice convening the meeting, and the minutes of the last meeting, which were confirmed,

The CHAIRMAN said: Gentlemen, you have had the report in your hands for some days, and I presume that you will take it as read. The report is a very full one, and contains an amount of information which will enable anyone who reads it to understand the movements and transactions of the Company. As usual, I shall go through the report, and refer to some of the eading points in it.

The receipts for messages during the six months ending March 31, 1891, amounted to £349,749, as against £348,624 for the corresponding period of 1890, showing an increase of £1,125. The total working expenses for the half-year ending March 31, 1891, amounted to £102,020, as against £98,477, being an increase of £3,543. Included in this year's figures, however, is the item of "special repairs to Alexandria buildings," £3,823, to which I referred at the last meeting. Several of the items show an increase, while others show a decrease. Before I give you the details, I think I may point out that the Alexandria buildings are a very fine block of buildings indeed, but unfortunately, dry rot got into them, and we had to take out the rotten deals and to put in iron. In other words, we had to make very extensive and very effective repairs, for our Alexandria establishment is a very large one, employing a great many hands, and one in which we have to put up our staff. It is a building that does great credit to the Company, and one we thought it was absolutely necessary to put in a thoroughly effective state, both as to the soundness of the building and its sanitary state as well. We have also, I may tell you, in this block of buildings a number of shops which we let off, and altogether it is a building which the Company has every reason to feel satisfied with.

The general expenses in London were £9,503, against £8,726, being an increase of £777, the principal in advertising and stationary. The working expenses at stations amounted to £75,003, against £72,677, showing an increase of £2,326. The necessary increase in the number and the additional pay and allowances granted to some of our foreign staff, to which I referred at our last general meeting, account for the increase in salaries and rent, fuel and light. The amount carried to the maintenance ships reserve fund is £3,000, against £5,000. We have had three of our ships—which is a very remarkable fact—at one time in London. I wish we had been able to keep them there, because our ships are never better employed than when they are in London doing nothing. Two of these vessels sailed the other day, and all of them are in thorough order. Although they are ready and able for work we would much rather that the ships should lie idle. Still, we keep them in such condition that they may be employed at a few hours' notice. To the Staff Endowment Assurance we put £2,366, against £1,688, being an increase of £678. Up to last year a certain number only of our staff had taken advantage of this Assurance scheme. The Directors, however, after 10 years' experience of its working, were so convinced of the benefits it conferred on the staff that they urged the remainder to join, and I am pleased to say that nearly the whole of the staff are now contributing members. This is an important point. All Government offices and most other important institutions generally make some arrangements whereby their staff is assured. Above all it is necessary in our system to have an efficient staff. We get the best men and we can only keep them by making them as comfortable as they could be in any other service. That is our policy, and so far it has succeeded. Now, by our system our men at 50 years of age can retire with a certain amount of money in their pockets. A man at 50 years of age in our service is not so valuable as a manipulator as a young man. Such men have an opportunity, by this fund, of retiring with something in their pockets, and starting afresh in life, if they wish to do so.

The expenses attending the repairs and renewals of cables amounted to £53,144, against £47,520, being an increase of £5,624. On reference to Abstract C, page 7, of the accounts, full particulars will be seen of the work performed by our ships during the half-year. The chief expense has been incurred in connection with the Red Sea cable, laid in 1870. We have succeeded in the removal of all the known weak parts and have laid in new cable, and it is believed that this line, which has been working since the formation of the Company, can still be kept efficient for a number of years, thereby increasing the security of telegraphic communication in the Red Sea. It is also encouraging in this way: there was a time when

Digitized by Google

people said that 10 years was the "life" of a cable; and then it got to 15 years. Here, however, is a cable that has worked for 21 years. We have taken out of it some weak parts and we have put in stronger parts, and we have now a thoroughly efficient cable. Perhaps experience may teach us that a cable may live for considerably over 20 years. All this is for the benefit of our Company.

After providing for all expenses and interest charges against revenue, we are able to recommend a final dividend at the rate of 5 per cent. per annum, and a bonus of 1½ per cent. for the year ending 31st March last, and carry £95,000 to general reserve fund, which amounts to £534,650 after the appropriation of a further £100,000 to the cost of the Suez-Perim-Aden No. 4 cable. I think you will agree with me that is a very satisfactory state of things, and I think as I go on I shall be able to show you that the policy we have pursued in adding largely to our reserve fund has been a very wise one.

Having dealt with the revenue and expenses, I will now give you some information about the capital expenditure on new cables and the financial arrangements incidental thereto. At the meeting in July last year I showed you the necessity of laying a new cable in the Red Sea from Suez to Perim, and from Perim to Aden, at a cost of £250,000. At the general meeting in January last you were informed that in anticipation of the largely increased traffic with Australia, consequent on the reduction of rates between Europe and certain Australasian Colonies, we had decided to lay a triplicate cable between Aden and Bombay of such a capacity as would give us a considerable margin of carrying power, to deal with any increase of traffic that might be at all likely to take place during the next few years. It has always been our policy to keep ahead of the carrying requirements of the Company, and it is satisfactory to be able to say that the encouraging results of the traffic since the reduction of rates to Australia has fully justified the foresight and prompt action of the Directors. To add to the security of telegraphic communication with Suakim, we have considered it advisable to duplicate the connection with that port by cutting into and diverting our No. 2 Suez-Aden Cable. This has caused an expenditure of about 226 miles of new cable. Notwithstanding these important and expensive operations, we do not anticipate any permanent additions to the capital account whatever. We hope to be able to meet this expense by appropriations from time to time out of our reserve fund. Gentlemen, the importance of what I am stating to you, viz: keeping down our capital, and of maintaining our power to pay you annually dividends such as we have done, is, I think, a policy of which you must all approve, and that is a policy which, I repeat, is the great strength of this Company. I shall show you further on that we have duplicated every cable. With the temporary assistance of the Eastern and South African Company, in which we hold fifty-nine sixtieths of the share capital, we shall be able to meet the payments as they fall due to the contractors without disposing of our reserve fund investments to any great extent. The financial transactions will take about four years to complete, and it is estimated that, at the end of that time, our position will be as follows:—The additions will have been paid for, and the whole amount applied out of the reserve fund. The Eastern and South African Company will have been repaid, and our capital account will stand at practically the same figure as at present—provided, of course, that no further extensions of our system are considered advisable. It is reckoned that the amount taken out of the reserve fund, from time to time, up to the date of the completion of these arrangements, will be about £1,500,000, and the balance remaining in the fund will be about £500,000. It is hardly necessary for me to say that the Company will, in consequence, be in even a better financial position than it is to-day.

During the financial year to 31st March last we have expended 769 knots of cable, while the amount used on repairs has been 460 knots. A portion of the cable expended was used in putting the Red Sea line in, as far as we know, efficient order. It may interest you to know that our ships have sailed during the year ending 31st March last, one way and another, no less than 112,189 knots, showing that they are constantly employed; and, indeed, without these ships we could not possibly exist.

We have now got all our cables duplicated, as I have already said. We have got four cables between Suez and Aden, and three between Aden and Bombay. These are very important sections. Altogether we have now a system of 26,093 miles, as against, in 1870, a mileage of 8,434, which practically represented the capital originally involved in this concern. Therefore this large addition from 8,434 miles in 1870 to 26,093 miles in 1891 has been done with an increase of less than £2,000,000 in the capital, and without in the slightest degree interfering with your dividend. A large amount has been taken from revenue, and at the same time we have materially added to our reserve fund. I think that is a state of things with respect to your property which it would be very difficult to beat.

I have now given you certain details which you will be able to carry away in your mind, and from the last point to which I have referred you will see that your property has been very safely protected. I may refer to another point—namely, that in our African traffic alone this last year there was a decrease of something like £49,000 compared with the amount we received from that source two years ago, when, however, there was a great deal of excitement in Africa, and money was expended very freely. Communication between Africa—the Cape, and Kimberley—with London was very active indeed. I cannot tell you the number of Mining Companies in London that were established, and they were all more or less in connection with Kimberley; and, consequently, we had a very considerable amount of traffic. For the moment that traffic does not exist, but there has been a growing legitimate traffic. The population has been increasing there. You must remember that there are cycles of prosperity, and cycles of rest, and I think the cycle of rest is now prevailing, and that we may look forward to the spirit of enterprise reviving. It is in the hands of Englishmen, and there is no doubt that the Cape is one of the future countries to which we have to look, not only for gold, but also for a largely increased consumption of British merchandise. There is another point which I think I may mention as interesting to you, namely, that these African cables in a certain period will belong to the Eastern Company—they practically do so now; but at the end of the period all the debentures will have been redeemed, and we shall, as I have already said, hold fifty-nine sixtieths of the capital. Now, as I told you, we have put our cables into thoroughly efficient order, believing that the reduction of rates to Australia was going to produce a large increase. That increase up to the present time—the reduced rates have only been in force three or four months—has been on the whole satisfactory. We have not recouped ourselves yet, and I do not suppose we shall do so within 18 months or two years; but I think I may say that we have so far recouped ourselves that when the end of the year comes we shall go on with the experiment. The Cape has applied to us to be put on the same footing, but that requires some consideration and some negotiation. I should like to see one experiment fairly tested before we enter upon another, and meantime things are not so very active at the Cape. Still, I hope and believe that this may eventually come, and when it does come it will give us what I call a Cape guarantee for our dividend, and that will add materially to the value of our shares; at least, that is my opinion.

When I last addressed you I told you that I was going to visit some of our stations in the Mediterranean, I have done so; and I am not the only person who says this, but all whom I have met who have visited these stations say they are most creditable to the Eastern Company. We have a good class of young men, our establishments are well conducted, and, altogether, we ought to be proud of the way in which our business is conducted in the Mediterranean. I went from there to Constantinople. I found there a very great disposition on the part of the Turks to keep up our friendly relations, and we opened certain negotiations which have proceeded, and through which we may be able to lay before you a matter for still further strengthening our relations with foreign Governments, and promoting our business. I then went on to Athens, and I found a very warm interest taken in our affairs in the Kingdom of Greece. Altogether I was assured that the way in which your business was conducted was thoroughly and entirely satisfactory to the Governments with whom I had the pleasure of conversing.

I think I have given you pretty well all the particulars that I desired to communicate to you, and, with these remarks, I beg to move the following resolution:

"*That the printed Report and Accounts of the Directors to 31st March, 1891, submitted to this meeting, be and the same are hereby received and adopted. That a dividend on the preference shares of the Company to 30th June, 1891, at the rate of 6 per cent. per annum, be paid, less income-tax; and that, in accordance with the Directors' recommendation, a dividend be, and is now declared of 2s. 6d. per share, with a bonus of 3s. per share, both free of income-tax, on the ordinary shares of the Company, making, with previous payments, by way of dividend on account, a total payment of 6½ per cent. on those shares for the year ended 31st March, 1891.*"

The VICE-CHAIRMAN (The Marquis of Tweeddale): I beg to second that.

The CHAIRMAN: If any gentleman wishes to ask any question before I put this resolution I shall be very glad to answer him to the best of my ability.

Captain GOODSALL: You spoke so favourably with respect to the Staff Endowment Assurance, that I should like to ask this question: Does that embrace the officers and commanders of the ships?

The CHAIRMAN: I see some of the commanders here to-day, and I think they will tell you that they are very well satisfied with the position they hold. During a voyage some five or six years ago across the Atlantic, the Captain of one of those vessels said to me: "Oh, if you would only take me into your service! I should think it not only a great honour to serve your Company, but a comfort which it is impossible to find here."

Captain GOODSALL: I grant all that, but I say why should not the officers of the ships have the privilege of sharing in the benefits of the Endowment Assurance? It would make no difference to the Company. May I also ask whether the last Aden-Bombay Cable was laid to the south or the north of the other two?

The CHAIRMAN: I think you will give us credit, after our long years of experience, that we should lay the cable where our engineer thought best.

Captain GOODSALL: The question I asked is whether this cable is laid to the south or the north. The south is the best side.

The CHAIRMAN: The answer I give you is this—that these matters are very carefully considered. They are not only discussed by our own experts, but we have the advice of a leading engineering house in London—Messrs. Clark, Forde, and Co., and they are the people who are actually representing your interest outside of the Board. When cables are being made, and until they are laid and in working order, they are put under the charge of our engineers, so that, apart altogether from the way in which the Board deal with this matter, we have independent men to look after the practical part of the business, just as we have auditors to look after our accounts.

Captain GOODSALL: Is this cable laid to the south or north of the other two?

The CHAIRMAN: To the south.

Captain GOODSALL: That is what I wanted to know.

The CHAIRMAN: Those in favour of the motion which I have read will please hold up their hands. To the contrary. Carried unanimously. That concludes the business of the meeting.

Mr. W. GRIFFITH: The position of the Company is so favourable that I think we should not separate without following our custom of passing a

Digitized by Google

vote of thanks to our Chairman and Directors. The resolution has been so often passed that it may appear somewhat formal, but I think on this occasion it will be thoroughly cordial. If we look at the report we cannot but be satisfied with the dividend and bonus which has been declared; and, further than that, I think we ought to thank our Chairman and his colleagues for the very sound and sensible policy which they have adopted. It is a great thing that many of these improvements in our position have been paid for out of our reserve fund, and that there has been comparatively so little necessity to increase our capital. Our capital keeps low, our shares are improving in value, and if this dividend and bonus continue, I think we have great cause to thank those who have been so instrumental in bringing about such desirable results. I move a vote of thanks to the Chairman and the Directors.

Mr. MAYNES: I beg to second that.

Mr. GRIFFITH put the motion to the meeting, and it was carried unanimously.

The CHAIRMAN: I beg to thank Mr. Griffith for the way in which he has proposed this vote of thanks to myself and the Directors. We have endeavoured to carry on this business in a way which would be not only satisfactory to our shareholders for the moment, but also to make it an enduring success; and, as far as one can see, our policy has been eminently successful in that direction. I do not suppose that at the present moment there exists a more complete system of submarine telegraphy; in fact, it is impossible. This is the most complete system of submarine telegraphy that has existed, and we hope to keep it still the first system. I will just say one word which you may carry away with you. We have come of age. It is 21 years since our main cables were laid, and in that period we have almost touched every port where the British flag flies. That is a work which we have done in 21 years, of which you have helped us by finding the capital, and we, who have been instrumental in carrying it out, ought to be very well satisfied. We have attained our manhood, and I hope that it will be used as advantageously as our youth.

The proceedings then terminated.

The Direct United States Cable Company (Limited).

The twenty-eighth ordinary general meeting of this Company was held at Winchester House, Old Broad-street, E.C., on the 17th inst., under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. T. Finnis) having read the notice convening the meeting and the minutes of the twenty-seventh ordinary general meeting, held in January last, and the report being taken as read,

The CHAIRMAN then said: I shall, as usual, go over some of the figures of the report before I make a few general remarks on the position of the Company during the last six months. The revenue for the half-year to the 30th of June, after deducting out-payments, amounted to £37,353, and the working and other expenses, including income-tax, but exclusive of the cost of repairs, absorbed £18,113, leaving a balance of £19,240 as the net profit of the half-year, making, with £5,510 brought forward from the previous half-year, a total of £24,750, which has been appropriated as follows:—interim dividend of 3s. 6d. per share for the quarter to the 31st of March, £10,624; proposed final dividend of 3s. 6d. per share to the 30th of June, £10,624; balance proposed to be carried forward, £3,502. That makes the total of £24,750 which I mentioned. The revenue for the past half-year has shown a falling off of £2,664 as compared with that of the corresponding period of 1890, due to slackness of business, to some curtailment of trade owing to recent fiscal arrangements of the United States Government, and to the temporary loss of traffic with the West Coast of South America, through the war in Chili. In the expenditure in London, as shown by Abstract "A" in the accounts, most of the items remain practically unaltered. There is an increase of £90 in the salaries, and a reduction of £82 in the printing and stationery item, these expenses on the whole being £19 less than in the same period of last year. The expenses at stations show an increase, on the whole, of £468, due to our responsibility for the full cost of the New York (Broadway) office for the complete half-year (as explained in paragraph 6 of the Report to the 30th of June, 1890), and to the establishment of a new branch station at 21½, Spruce-street, New York. The cost of repairs during the half-year has amounted to £2,188, which has been charged to reserve fund account, as usual. On the other hand that account has been credited with £4,365, for interest on the investments, leaving the balance of the reserve fund account at the increased figure of £254,854. The investments, which have been increased from £234,993 to £244,652, are entered in the balance-sheet at cost, which is a figure considerably below their present market value. Gentlemen, that gives you something like the hard facts connected with the working of the Company during the last six months. I have been looking over the notes of the last two or three half-yearly meetings, and really I have told you so much in the past that it is very difficult indeed to say anything new on the present occasion. With the existing depression of trade and the kind of cloud which is hanging over commercial enterprise generally, we are affected, and are participating, to some extent, in the evils resulting from such a state of things. I have always said on these occasions that telegraphy is a good barometer of trade. With buoyant trade we have buoyant traffic; with depressed trade we have people buttoning up their pockets. While telegraphy is, more or less, a necessity, it is a luxury in commercial enterprise, and merchants endeavour, as far as possible, to cut down expenses when they find that their incomes are not such as they have been accustomed to. There is one thing which I have pleasure in stating—that with all the difficulties and all the troubles that have surrounded submarine telegraphy in the Atlantic for some time, I think I may say, with perfect safety, that there is no company at the present moment occupying a better position than the Direct United States Cable Company. I will show you that by figures. There is no better field for telegraph enterprise in the world than that of the Atlantic, for there are the two great English-speaking people to communicate with one another through the wires at either end, and the enterprise of the English people is proverbial. They dominate the commercial world, and when they are active they are particularly active in the United States; and I am looking forward—not without some reason, I think—to a renewed amount of energy on the part of our kinsmen beyond the sea. There is an exhibition coming forward there, and no doubt they will try and make that the finest thing of the kind which has yet been done, and I believe that they will do it. To do it requires, however, a great deal of energy, a great deal of time, and a great deal of money, and I believe we shall get some portion of that money on our system. It is always pleasant to talk to people who are interested in any particular subject, and you, as shareholders of the Company, are directly interested in this system. There is an old saying—I believe it is a German saying—that it is always pleasant to send you away with a pleasant taste in your mouth; and I am going to show you that, as far as this Company is concerned, you may be satisfied that, as regards Atlantic submarine cables, your property is about the best of the whole. The figures I am going to mention to you are interesting in this way—that they show you exactly the market value of the different companies' cables at the present moment. I am sure it will interest you. It always interests me when I look at it, and I do not think that I have ever before given you these details. I will, therefore, do so to-day. I will first of all take the Anglo-American Company. The original capital of that Company was £7,000,000, and its market value to-day is £3,220,000. Their reserve fund is £980,948. The present market value of their property, less the reserve fund, is £2,239,052, or equal to, per cable—this is the point I wish to bring you to—£559,763. That is, each of the cables of the Anglo-American Company stands at the present moment at a cost of £559,763. They pay a dividend of 2⅞ per cent. upon the £7,000,000, but this yields to the investor, at the present price, 6¼ per cent. Now I will take our position. Our original capital was £1,214,200, and its market value to-day is £652,632. Our reserve fund is £254,854. The present market value of our property, less our reserve fund, is, per cable, £397,778. Our dividend, as you know, is 3½ per cent., and, upon present prices, that is equal to a dividend of 6½ per cent. The capital of the Western Union Company is £2,800,000, and its market value is £2,240,000. They have no reserve fund. The present market value of their property is £2,240,000, equal to, per cable, £1,120,000. Their dividend is 5 per cent., but it is guaranteed by the Western Union; and they yield to the investor, their capital being at a discount, 6¼ per cent. The next company I will deal with is the Commercial Company. Their capital is £1,643,200, and they have debentures amounting to £320,000, so that altogether their capital is £1,963,200, the market value of which is £2,080,992. Their reserve fund is £220,000. The present market value of that property, less the reserve fund, is £1,860,992, equal to, per cable, £930,496. Their dividend is 7 per cent., but the yield to the investor, at present prices, is 6⅝ per cent. With regard to the French Company their capital is £1,680,000, and its market value is £428,400, which is equal to, per cable, £428,400. That Company has only one cable, and it has no reserve fund and pays no dividends. Now, this is an extraordinary position, and I will repeat this part of it—that each cable of the Anglo-American Company, according to the present market value of the property, less their reserve fund, is £559,763, whereas in the case of the Direct Company, it is only £397,778. That is an enormous advantage for the Direct Company. We stand at the lowest possible price. We could not possibly put down a new cable for the same price as the cable stands at the present time. I therefore think that we may congratulate ourselves that, what with the value of our cable, and our reserve fund of £254,000, we are by far the best property of any in the Atlantic. I think you will agree with me in that, and I think it is a circumstance which should leave a pleasant impression on your mind. I only wish that I could add to that that the prospects are such that we may soon return to our old dividend of 5 per cent., but when we were paying that dividend there were only about six cables in existence. Since that time, however, the cables of the Western Union have come in, as well as two more cables of the Commercial Company. We never earned at any time more than about £950,000 a year; we never got up to £1,000,000 for the whole of the Atlantic traffic. That, too, was at 2s. a word. At the present moment we earn practically £900,000, or very nearly as much as at the former rate, but this amount is divided among 10 cables instead of among six. In addition to that, science has given us the power to transmit over our cables just double the quantity of traffic that we used to be able to send over a single cable. The duplex system has doubled the power of carrying, and, therefore, I may say that, at the present moment, we have practically 20 cables in the Atlantic to do the business and to be remunerative. Believing, as I do, in the growth of submarine telegraphy, nevertheless it takes a long time to make up an amount of traffic to fill 20 cables as compared with six or eight. I think you will all understand that point. Now, we make the greatest possible effort to gather traffic, and there is a competition, and an active competition, going on just now, probably more active than profitable, among the Atlantic cables to get hold of the traffic. When I tell you that active competition has cost the companies between £30,000 and £40,000, it shows you that pushing and energy to obtain traffic may be carried a little too far. I believe it has in the present instance been carried a little too far, and whenever a matter like this is carried to a point when it is not profitable, I think you should consider whether it is best to alter your tactics. I never like to sow where I cannot reap, and I never like incurring expense which I cannot recoup by a profitable return. This is a question that requires the consideration of all the companies, and I think that, as things are going on now, the day is not far distant when we may have this question thoroughly considered among the companies. There is another cause accounting for the depression in Atlantic telegraphy. At the present time I may tell you that there is a positive

Digitized by Google

decline in Atlantic telegraphy, and it is said that the McKinley Bill has had something to do with it. I think there is no industry in this country which has not thrown a stone at the McKinley Tariff Bill, but I think the parties who are likely to suffer more than any other people by it are the people of the United States. The idea of any one nation living on itself alone—upon its own resources—is the greatest fallacy, and we destroyed that fallacy in the free-trade principles which we adopted many years ago. I therefore think that that will practically come to an end in time. There is one thing, I think, that you may rest assured upon—that the world can no more do without submarine telegraphy than it can do without food. The populations of the different countries where commercial enterprise exists are all—more or less—leaning on the old country. They must come to us; we are the banking institution of the world, and they must lean on us. Submarine telegraphy, therefore, which connects the old world with the new, must always be a growing factor in civilisation. That is the broad view which I take of submarine telegraphy, and I only regret that at the present moment, in regard to the particular part of the business in which we are interested, there is just a trifle too much—there is a plethora of power to carry on the work; and until we fill that up I cannot hold out any great encouragement of an increased dividend, but that it is gradually filling up and gradually growing I have not the slightest doubt in my own mind. Those who came into this Company at the reduced price of the shares are getting a very handsome dividend on the money which they have invested in it, and, therefore, I think they will be satisfied to rest and look on in the hope that even that dividend which they are receiving now, handsome as it is, may be increased in the future. There is only one other point which I have to say a few words upon,—I refer to the French suit. I was asked about that at the last meeting. Since then the French Courts have, I believe, decided in our favour, but there is an old saying, that it is very difficult to get a bone out of a dog's mouth, and it is very difficult to get money out of any French institution, particularly if it is to come to England. Therefore, I do not wish to buoy you up in any way on this point. We have gained the suit, and that shows that we were right in going into it, but what money we are going to get out of it I must leave to mention six months hence. I now propose:

"That the report of the Directors, dated July 8th, 1891, together with the statement of accounts to June 30th, 1891, annexed thereto, be, and the same are hereby received and adopted, and that a final dividend be now declared of 3s. 6d. per share, free of income tax, making, with the interim dividends already paid, a total dividend of 3½ per cent. for the year ended June 30th, 1891."

Mr. WILLIAM FORD: I beg to second that.

Mr. JACKSON said that the Chairman had given them some very interesting remarks in reference to the return on their investment in the Company as showing a result more satisfactory than that of any other Atlantic cable property. He had, however, been very much surprised to hear the Chairman quote the Commercial Company, and say that the Direct were doing better than that Company, for the net return on the capital subscribed to a company was the test of its success. In judging of the prosperity of a company the net return was the *crux* of the whole question. The Commercial Company, which was the youngest competitor and with the least experience, was making a 7 per cent. dividend, while its shares were above par. He did not think that any amount of figures could alter that fact and reduce that Company to a condition inferior to that of any of the Atlantic Cable Companies. He supposed that the lawsuit referred to had been in the hands of the Anglo-American Company, though, no doubt, with the advice of the associated companies. He had been in hopes that the Chairman would have been able to say that the award—which they must look forward to, having got a verdict from the Council of State—had been received. He thought that the Pool Companies were bound in duty to press the fact before the French Courts that the intrigues of a man who was discredited as a man of the worst kind had brought about the capture of their partner cable, and if they were to have no compensation for that, he thought that the Boards of the various Atlantic Cable Pooling Companies would fail to do their duty to their shareholders. The Commercial Company had thriven through having strengthened its force through this capture, which was done by an act of a very base kind. Having made these remarks he had much pleasure in supporting the motion.

The CHAIRMAN: I suppose that no other gentleman has any remark to make, and therefore I will reply to Mr. Jackson. I think, if I remember rightly, in speaking about this lawsuit six months ago, I said that I thought I had used language about it in Paris that might have led to an affair of honour. I am not going to say much more than that. We are in the hands of the French Courts, and are being advised by French legal gentlemen of the highest standing, and we are more or less bound to abide by their decision. This is a question, as Mr. Jackson knows, which is entirely in the hands of the Anglo-American Company. We are, no doubt, interested in it—we participate in the result—but we are not in any way connected with the conduct of the suit except as we may say "Yes" or "No" to any proposal that may be made with regard to it by the Anglo-American Company. That Company has consulted us all through in this matter, and they continue to do so now. The secession of the French Company from the Pool was a disadvantage in so far that it enabled the Commercial Company to command a certain amount of French influence and a certain amount of French traffic, and gave them for the time being an additional cable to carry on their competition against the seven other cables. In that respect there is no doubt at all that it did us serious harm, and in all probability the damages will accrue on this, as on other points. As to the other question which Mr. Jackson raised, I had a note about it, but I thought it was not worth while to draw attention to the very anomalous position of the Commercial Company to which he has referred. They are paying their dividend on their full capital. We pay a dividend on our full capital, but it only gives a result to present investors equal to the dividend paid by the Commercial Company. What is the position of the Commercial Company? It is, comparatively, a private Company. It has a newspaper connected with it on the other side of the Atlantic. Why do they get so much more traffic than we do? It is in this way. When they started first they went to the different telegraphing people that they perfectly well knew, and they said to these people, "If you will stand by us for a certain time, we shall reduce the tariff from 2s. to 1s. 8d." The result was that the people who had made a promise to support the Commercial Company were bound, to a great extent, to support that Company against the other companies, believing that they were the pioneers of the reduction of the tariff. They have, therefore, had a decidedly larger share of the traffic than we ever expected they would get. However, the obligations that were entered into at that time will come to an end, and the cable company which has the largest number of lines, and which can do its business best, is certain, in the long run, to get the telegraphing business into its hands. I think the result of what is going on now, and the extraordinary anomaly that exists as to the different cables, will very soon be adjusted. All I can say is that I should be very sorry—extremely sorry, indeed—to have my money invested in the Commercial Company with its stock at a premium, as against the Pool Companies, with their seven cables and all their properties at a discount of from 50 to 20 per cent.

The motion was then put to the meeting and carried unanimously.

Mr. E. M. UNDERDOWN, Q.C., then proposed the re-election of Sir John Pender as a member of the Board and Chairman of the Company. It was, he said, unnecessary for him to say any words with reference to Sir John Pender's conduct of the business of the Company, or of the business of the other companies with which he had to do. A most remarkable statement was made by their Chairman on the previous day, at the meeting of the Eastern Telegraph Company, which he (the speaker) understood had tripled the length of its system without calling on the public for one penny, and had made this magnificent addition out of earnings. That was not the only achievement of Sir John Pender, but of this all who were in the telegraphic world were well aware. With reference to the point raised by Mr. Jackson, as to the amount of the dividend on the capital of this Company, he believed that that gentleman was a shareholder in the Company before he himself was, and he believed that he (Mr. Underdown) was a shareholder in the Company before Sir John Pender. Therefore Mr. Jackson's shares and those of himself stood at a rather higher figure than they would like to see them, but he thought it was their duty to their Chairman to say that they must be taken to start from the year 1877, and he believed that very few remained among them who were holders of the original shares.

The CHAIRMAN: Five per cent. or six per cent.

Mr. UNDERDOWN, continuing, maintained that the Directors had increased the nominal value of the shares—that was, their equitable value as they stood at that time. They had maintained a very respectable value for them as they now stood, and if we pay 6¾ per cent. on that, then Sir John Pender and the Board were doing very nearly as well as the Commercial Company, if they took the point they started from. However this might be, it must be very satisfactory to them to know that their little Company had maintained the position it had, as between the other companies, and this was a fact due exclusively to the services of Sir John Pender, who had contributed so much to the general prosperity of submarine telegraphy.

Mr. WILLIAM FORD seconded the resolution, which was carried unanimously.

The CHAIRMAN: For the very complimentary way in which Mr. Underdown has again brought my name under your notice I thank him, and I thank you for accepting Mr. Underdown's motion in the unanimous way in which you have done. The reason why I have devoted so many years to telegraphy has been that I have regarded the work not only as a labour of love, but of deep interest, and I have given to it deep anxiety and active thought. As I have stated, we have had difficulties in the Atlantic, which is the finest field in the world for submarine telegraphy, for whereas at one time the Americans would not look at the enterprise, they at last came in in a volume and upset the pioneer. I have no doubt, however, that that is a matter which will right itself. I believe in English energy and English dogged perseverance, and I believe in this work upon which we are engaged. I have not now a very long term before me, but while I have the energy which I possess to-day, I intend to use it for maintaining English right and English might whenever it may be necessary. Continuing, the Chairman proposed the re-election of Mr. William Ford as a Director of the Company. He referred to Mr. Ford's recent severe illness, owing to an attack of influenza, and congratulated him and the Company on his recovery. He believed that Mr. Ford had never been absent from one of their meetings during the time he had been connected with the Company. His colleague's energy as a Director was very great, and he was one of those men who are always endeavouring to do what is right and just for the interests which he represented.

Mr. CHARLES MEARA seconded the resolution, and it was carried unanimously.

Mr. FORD, in reply, briefly expressed his grateful appreciation of their kindness, and said they would pardon him on that occasion for saying nothing further.

On the motion of Mr. W. S. CUFF, seconded by Mr. JACKSON, the Auditors, Messrs. J. G. Griffiths and John Sawyer, were re-elected.

The CHAIRMAN then intimated that that finished the business of the meeting.

Mr. JACKSON said he thought it was a duty they all owed to the Chairman to thank him and the Board for their management of the Company's affairs. At the same time he desired to repeat his opinion that

Digitized by Google

while 3½ per cent. was very good for a guaranteed or preferred dividend, it was not all that they could wish as ordinary shareholders.

Mr. W. GRIFFITH, in seconding the motion, said it might be that those who joined the Company when the shares were high might not be altogether satisfied, but the later shareholders had strong reason for being satisfied with the present and with the good hopes which were held out for the future, and those hopes were sure to be realised under the present able management. Few persons possessed such ability and capacity for conducting business as Sir John Pender and his colleagues, and it was with much pleasure he seconded the resolution.

The motion was carried unanimously.

The CHAIRMAN: In the name of my colleagues and myself I thank you. Nothing pleases me more than to have that sort of criticism which Mr. Jackson brings forward from time to time. I think we all require a little pricking up occasionally. It does us no harm, and therefore I accept Mr. Jackson's principle of using the spur sometimes. I have, however, told him that we have such a plethora of cable power in the Atlantic just now that it is very difficult indeed to bring the telegraphing public up to the scratch; and, after all, they are the people who are to give us the increased returns which we want. I hope—and it is a natural hope—that we shall participate in such returns, but we have such a power to carry the traffic—so much more than we really want for carrying it—that until the two factors, supply and demand, get a little more assimilated, we cannot hold out any great hope of increasing the dividend on our original capital. I thank you very much, and I hope that we shall have the pleasure of meeting you often, and of having as pleasant a discussion as we have had to-day.

The proceedings then terminated.

The Edison and Swan United Electric Light Company (Limited).

The annual meeting of the shareholders in this Company was held on Tuesday, at the Westminster Palace Hotel, Victoria-street, S.W., under the presidency of Mr. J. S. Forbes.

The SECRETARY and MANAGER (Major S. Flood-Page) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, we have to apologise to you for bringing you to Westminster. The fact is that the City Terminus Hotel, where we usually hold our meetings, is so exceedingly busy that they could not give us a room, and so we came here. The report and accounts have been printed and circulated, and I suppose you will take them as read. (Taken as read.) Well, then, taking them as read, I assume you know all about them. I do not know whether any gentleman has gone through the agreeable exercise I have done during the last 24 hours of reading all the reports from the beginning—that is since 1884. We are now dealing with the eighth complete year of the undertaking, and I discovered a very singular thing, that all the early reports gave what is called very full information. I have been conversant with reports of different companies for a great many years, and I find that it is the characteristic of all those reports in that where the dividends are short they are long. It seems to indicate this, that when a company has emerged as we have done from some of the preliminary difficulties and trials, there is very little to say. It is your acts, not your words, which help you then—how much profit you have got. Happily for us, our reports gradually diminished in length almost as the dividend has increased in amount; and this report before you to-day is one of the shortest we have ever had, and, I hope you will think, as we do, one of the most satisfactory, because it reveals one or two primary things of some importance, namely, that the bulk of the business has increased and the profit has increased and we are enabled happily to dispense in respect of the year and of the arrears accruing due to the "A" shareholders a larger amount than we did last year and than we did in the preceding year. That is the whole of the story. However, one may enlarge upon it, and call your attention to the details, I have been an apologist for so many reports and accounts, that when there is nothing to say I am rather non-plussed; the whole of the story lies in the figures. Well, now, the figures, so far as they concern any joint-stock company's accounts, are not quite so full as those with which I am in the habit of dealing; but the essence of them lies in the profit and loss account, which is the first in this report, and there you will see on the one side the income and on the other the cost of obtaining it. I propose to take you through the income, in order to compare the year with which we are dealing with the preceding twelve months. The first item is by sale of lamps, fittings, royalty on holders, and so on, £143,229. 14s. 11d. Now, the corresponding heading last year revealed the figures, £118,865. 15s. 1d., so that the amount of sales has increased by £24.364. The next item of revenue is interest account, £427. 12s., against £1,442. 17s. 1d., or a diminution of something over £1,000, arising from the fact that in the course of the preceding year we realised the bonds of a certain company on which was paid 4 per cent. interest until we took them over and converted them into money. That affected the interest. The drawings on our bankers have been a little more than they were last year, and the interest account has been turned slightly against us. Another item which we deal with as income represents stock on hand. That has been explained to you a great many times, so that it is familiar to all those who attend our meetings and those who read our proceedings. We are bound in the very nature of our business to keep a large amount of money locked up in stock. There are one or two great types of lamps—16 c.p. lamps—and small ones of other types, which are themselves subdivided into others of more or less power, and this circumstance involves this, that in order to meet the necessities of a great many of our customers and their varying requirements, we are obliged to keep a large supply of lamps on hand ready to meet any call that may be made upon us. June and July are the slackest months as regards electric lighting, but we must make sufficient provision now for the darker days, and not postpone the manufacture of the lamps until they are absolutely wanted. You will see that the stock last year was £56,266, and this year it is £59,308, which is a large amount of money to have locked up in the business. I must here qualify myself by saying that a considerable portion of the amount is not for lamps at all, but for platinum. In face of the possibility of a great rise in the price of the metal, we had to secure a large quantity of it at prices which were subsequently greatly exceeded in the market. We have now £15,000 worth of platinum in stock. The rest of the figure is made up of lamps and other manufacturing material, which must be kept in stock from time to time. Turning to the opposite side of the account, you will see what the cost of production has been. Dealing with the stock in hand on July 1st, you will find that we have increased it by £3,042. Wages, purchases, &c., amount to £56,362 19s. 6d., which represents the manufacturing cost at the factory. Wages is one of the things that do not diminish. Purchases mean material for the lamp itself, which is formed of glass, platinum, carbons, &c. Then comes salaries, Directors' remuneration, rent, office expenses, insurance, income-tax, general and law charges, £15,270. 6s. 7d. Then depreciation on plant, &c., written down as you see to the extent of £2,160. 18s. 10d., which we consider a safe quantity, being £300 over that of last year. Then the balance is £72,905, as against £61,115. That is the result of the trading for the year. I do not know whether you will consider it a satisfactory result. We think it is. We think that £11,800 more profit for the year is rather a good indication of the value of the business. When you see that the output leaves such a considerable profit as £73,000, it is not a bad business, enabling us, as it does, to recommend you to pay 7 per cent., which you are entitled to in preference to the deferred shareholders. But we must not give rise to any illusions, nor is it desirable that the outside world should believe that 17 per cent. is the normal condition of this Company. It may be just as well to know that in 1884 we paid nothing, in 1885 we paid nothing, in 1886 we paid nothing, in 1887 nothing, and in 1888 we paid nil. It was only the confidence which the Directors had in the soundness of the thing, and your confidence in the Directors, which carried them through the difficulties of those years when there was nothing to divide. That confidence has been justified by the results. Once the patent rights were settled, once the Company got upon its legs it began to pay. In 1889 for the first time we found it prudent to pay a dividend, and we paid 10 per cent., in 1890 we paid 15 per cent., and now we propose to pay 17 per cent. As that seems a large amount I daresay it will excite the cupidity of certain people, but if you will divide 42 with what we have divided with your sanction, it comes to the modest £5. 5s. per cent. per annum—not too great a reward for an enterprise of this kind. That is the outcrop of that part of the business. On the other side of the account, the balance-sheet—I do not know if it is worth while going through that. Perhaps I had better. On the debtor side you will see that the share capital remains practically intact. I mean it is not altered, there being the same number of £5 shares fully paid up and allotted to the Edison Electric Light Company (Limited). There is the same number of shares to the Swan United Electric Light Company (Limited)—the same number of "A" £5 shares, with £3 paid up, and the same number of "B" £5 fully paid up; so that our capital is £471,298. You see that, as far as the first of these are concerned, they are entitled to a 7 per cent. cumulative dividend in preference to the ordinary—not only to 7 per cent., but, in respect of the years during which you got no dividends. The first item which admits of comparison is the sundry credit balances. You owed last year £26,257, and this year £14,706. Coming to the reserve fund, we have been able to bring it up to £12,689 from £4,595, at which it stood last year. Then comes the profit and loss account as per appropriation, £69,479. When we come to appropriation we do not divide close up. We thought it prudent, after providing 7 per cent. on the current year, to complete the payment of arrears in respect of the cumulative preferential dividend owing in respect of the year ended June 30, 1885, at the rate of 3 per cent., and to pay 7 per cent. on the arrears of the cumulative preferential dividend for the year ending June 30, 1886. I have told you that in the years 1884, 1885, 1886, 1887, and 1888 there was nothing paid. We have squared it down, year by year, until we have now got 1886 balanced, and we have got 1887 and 1888 still remaining as a charge on the future, in respect to which you have had no dividend. Coming to the other side of the account, by cost of patents, goodwill, preliminary outlay, loss on working, &c., as per last balance-sheet, the further expenditure there has reference to payment for patents and legal expenses connected with the founding of the Company and its development. Against that we write off, from time to time, the amounts realised by plant, forming part of the original foundation price, but which, either from being out of date or being superfluous, we carried to the credit account, and we deduct the loss on realisation of original dynamo account £3,425, and that brings the amount down to £234,638. The amount of "B" shares of this Company issued as *per contra* is £117,820, the Manchester Edison Swan Company, Limited, 100,000 "B" shares at nominal cost. That is a deferred interst we have got in the future of that Company. Whether it will be worth that or not time only can reveal. I trust the £117,820 will bring to the owners of the "B" shares in this concern, sooner or later, something which will be a useful asset; they are entitled to one-fourth of the balance of the profits of the Company after a preferential cumulative dividend of 7 per cent. has been paid to the holders of the "A" or ordinary shares, and I hope that our profits are not going to diminish when the arrears are paid off. I think they will very likely go on. Then you come to freehold property, £45,012; plant and stock, £83,188; the fact being that during the year, in anticipation of and in order to meet the current pressure, we have been obliged at the factory to spend a considerable sum in putting up new glass blowing works. This is all under the pressure of a growing business. The money you see represented there is £45,000. We

Digitized by Google

bought the property originally very cheap, and I have no hesitation in saying that if that property were valued to-day for the purposes of a well-established going concern, it is worth a vast deal more than £45,000. If we had to buy land and bu ld factories, it could not be done for the money. Fortunately we found ample land, with a structure upon it. The people who put it up had made an enormous loss, and we bought it cheap. It is as good for our purpose as if we had put it up specially. Debtors stand at £34,859, as against £15,203. Considering that the debtors are all good, and that the money owing to us is about double what we owe, that is a satisfactory state of things Investment in Consols at cost is £20,000, and cash at bankers £8,051. That is the end of that part of the business. Now, coming to the appropriation of this £73,000, the profit and loss as per appropriation account is £69,479. There is one item I wish to call your attention to. Amongst other things we took over originally was a quantity of machinery, installations, and all sorts of things—the fruit of the want of knowledge of the two original companies, the Edison Company and the Swan Company. They made a lot of bad bargains. They bought a lot of stuff which has turned out to be effete—dynamos and things of that sort, and some installations founded on the theory that the rental of light was a very profitable thing. The theory was a very good one, but the practice was very bad, and, instead of being profitable, it was found to be exceedingly ruinous in cost. All this is a thrice-told tale. But men are such babies that they hesitate to realise at a loss at the right moment. We realised at a loss, and got rid of all these things on the best terms he could, and this is one loss—the very last. We had a lot of dynamos which were quite useless to us, but we managed to sell them in Italy, and we got rid of them the other day. A dividend of 7 per cent. for the year works out to something less than £25,000 ; then there is the payment of the balance of cumulative preferential dividend, at the rate of 3 per cent., £10,604, and payment of cumulative preferential dividend on the "A" shares at the rate of 7 per cent., £24,743. We thought that was going far enough, and we have carried the rest to reserve, and I hope you will approve that recommendation of the Board, because it is in your hands, not ours. These are the bare bones of the account. There is one thing I should just like to call your attention to. Of course, we are face to face now with this —there is so much capital ; a very large sum of money, and the patents are running out in two years and a few months. One looks with some anxiety on the past of a concern of this kind—the cost of patents, goodwill, the loss on working, and so on. That pulls down to £234,638. 17s. 7d. That is a considerable amount, but I do not think it is one that need alarm you. It is the cost of founding this business and carrying it through to that moment when we shall be in competition with the whole of the world. It is best to say it ; it would be silly if we did not say it, but we have the most perfect lamp factory in this, or, probably, any country of the world. I think ours has the best reputation of any lamp in any country. By the great perseverance and exceeding skill on the part of your technical advisers, and by the great zeal and energy on the part of the officials, you have had established a going concern on a very large scale, but this, as other large businesses, cannot be conducted without the investment of a great deal of money, and, therefore, those people who are going to compete with us will compete with us thoroughly equipped, and with a reputation thoroughly established. We shall have to take our chance for the future ; but it will come to this, I suppose, that although during a certain period, when enormous risks had to be run, when the public had to be educated in these things, and when it was a question whether success would attend you or not, you had a protected period, and rightly so, and there are blatant people who cry out about monopoly, and who will be prepared to say, though you are able to make a better lamp than you are doing, or at all events as good a one, at a price below any small maker, or any considerable maker, still you must take your chance with the public. If, however, we can double or treble our present sales in the two years and the few months yet remaining of our patent rights, and, when the time comes, if we can afford to take a very modest profit on our enormous ouput, we shall be in a comparatively strong position. Major Page calls my attention to the fact that we are not dependent on the lamp patents as covering only a certain time ; but we have patents in respect of very important parts of the lamp, sockets, and fittings, which extend a long time beyond the lamp patents, and from which we hope in the future to derive a very considerable income in the shape of royalties, and which may be very valuable. This, then, is the result of the working of this concern. We are not only now paying this assured dividend with the arrears, which will possibly be continued in the future for some considerable time, but in the interim, from 1884 to 1891, we have written down £301,000 to £234,638, and everybody knows that so much less to pay is a thing that you can contemplate with equanimity. That has been done out of the profits of the undertaking ; some of it out of the sales, superfluous plant and property, but most of it out of the profits of the undertaking. We kept writing down and writing down before we paid any dividend at all. The loss of the business had to be compensated before we began to distribute a dividend. It was not because there was not a balance to do it, but it was because we had large arrears in the shape of bad investments to write down. Therefore, you are in this happy position, that the original claim to be liquidated has been reduced by £66,000. One of the interests of a company like this is that we should be very cautious about our details. It is already quite bad enough in a joint-stock company, which is obliged to submit in black and white, from time to time, a certain number of details of its business. Prosperous people who manage their own affairs keep such things to themselves, and we are obliged to keep as much as is necessary to ourselves, because many people would like to know where we get our profit from, and so on. They may induct as much as they like ; but inductions are not as good as positive information. You must be good enough to believe there are reasons for dealing in generalities. Therefore, roundly speaking, your position is this : that your improved investment is put down at something like £125,000. I think that fact, coupled with the dividend you are getting now, is not altogether discouraging. With these remarks, subject to my readiness to answer any question, I move—

"That the report and the accounts for the year ended June 30th be received and adopted."

Mr. F. R. LEYLAND seconded the motion.

Mr. PELL asked whether all the lamps made by the Company were marked "Edison and Swan," as he had seen a great many not bearing any mark at all.

The CHAIRMAN replied that the bulk of the lamps were made by themselves. They had a few from Edison, which were marked "Edison," but their own was much the largest number. If the hon. proprietor saw any lamp not marked, perhaps he would kindly intimate it at the office.

A SHAREHOLDER asked how many lamps were represented by the item in the profit and loss account by sale of lamps, &c., £143,229.

The CHAIRMAN said it was a piece of information that he could not give, inasmuch as it would be very useful to their opponents.

A SHAREHOLDER wished to ask a question about the unnegotiability of the shares. He was a fortunate holder of the Edison and Swan shares, which he had no difficulty in getting, but he had the greatest difficulty in dealing with them. Some people might want to administer their affairs, and, in the face of that, he wished to ask whether they could not get a quotation for these shares.

The CHAIRMAN said that they had been advised by a very eminent broker, who told them that there was a great difficulty about this question. He thought that it, to a great extent, arose from the fact of the shares of the Edison part of the undertaking having been brought into the amalgamation under very different conditions from those of the Swan. The latter had no assets in the shape of foreign patents. In order to work those patents they had kept up their separate existence, and the difficulty was this, that they held the major part of the shares in this Company. They had been talking over the matter for years to see if they could not come to some arrangement by which the Swan Company would be absorbed by this Company, but they had not been able to do it. He quite appreciated the disadvantage there was about it. On the other hand, the Swan people might have some views about the advantages of keeping it where it was. At the same time, one could not conceive that it might not be done whenever it appeared opportune or wise to do it.

A SHAREHOLDER asked whether they were in the same position in respect of holders as of lamps.

The CHAIRMAN replied in the affirmative, adding that the difference between the holder of the lamp patent and the other was this, that the Company had reserved the absolute right to manufacture and sell the lamps, but they had licensed a great many first-class firms to be manufacturers of these holders and sockets for incandescent electric lamps under the Company's patents.

Another SHAREHOLDER advocated as a measure of safety the continuance of the investment in consols, and thought they ought to be grateful to the Directors and management generally for the masterly way in which the accounts had been presented.

The CHAIRMAN said that the previous speaker might rely on his suggestion receiving the attention of the Board. They had gone on the principle of making things safe. He could remember the time when, at meetings of that kind, things were not so pleasant as they were. Of course the shareholders knew that some of the Directors were interested very largely, financially, in this undertaking. Others were not so largely interested, but they had the same disposition to safeguard the interests of the proprietors. He then moved :—

"That a dividend at the rate of 7 per cent. per annum be, and is hereby, declared on the 'A' shares of the Company for the half-year ending June 30, 1891 (making 7 per cent. for the year), and of 3 per cent. in completion of payment of arrears of Cumulative Preference Dividend for the year ending June 30, 1885, and of 7 per cent. in respect of arrears of Cumulative Preference Dividend for the year ending June 30, 1886 ; all to be distributed in accordance with the provisions of clause 87 of the Articles of Association."

This dividend works out to the following amount per share :—On the 89,261 ordinary shares, 8/3$\frac{27}{32}$ per share ; on the 5,000 fully paid, allotted to the Edison Electric Light Company (Limited), 13/10$\frac{7}{8}$ per share : on the 12,139 fully paid, allotted to the Swan United Electric Light Company (Limited) 11/8$\frac{3}{4}$ per share.

The motion, which was seconded by Mr. LEYLAND, was carried *nem. con.*

Mr. LEYLAND then assumed the chair and proposed the re-election of Mr. Forbes to his seat at the Board, paying a warm tribute to that gentleman for the ability and interest he had shown in promoting the interests of the Company.

Viscount ANSON seconded the resolution, which was cordially agreed to.

Mr. FORBES resumed the chair and thanked the meeting for his re-election. In common with his colleagues, he said, he would always do his best to protect the interests of the Company and make it a valuable property for the future. He then proposed the re-election of Mr. Leyland to his seat at the Board, paying a similar compliment to that gentleman by saying that it was owing to his great experience and knowledge, backed by the assistance he received from his colleagues, that the Company was rescued many a time from great peril.

Mr. ERNEST VILLIERS seconded the motion, which was carried unanimously.

Mr. LEYLAND having thanked the meeting for his re-election,

Mr. PELL proposed, and a SHAREHOLDER seconded, the re-appointment of the auditors, Messrs. Welton, Jones and Company.

The motion was agreed to unanimously.

A vote of thanks having been passed to the Chairman and Directors, the proceedings terminated.

Globe Telegraph and Trust Company (Limited).

The following is the report of the Directors, to be presented to the eighteenth ordinary general meeting, to be held at Winchester House, Old Broad-street, London, E.C., on Tuesday, the 28th July, 1891, at 1 p.m. :—

The net revenue of the Company for the year, after deduction of expenses, amounts to £201,698. 12s. 1d., which, with the balance of £118. 18s. 6d. brought forward, makes a total of £201,817. 10s. 7d. From this amount there has been distribut the sum of £133,059. 5s. 3d. in interim dividends, leaving an available balance of £68,758. 5s. 4d.

The Directors recommend the payment of a final dividend for the year of 3s. per share on the preference shares, and of 4s. 6d. per share on the ordinary shares, making, with the former distributions, a total dividend for the year of 6 per cent., less income-tax, upon the preference, and 5¼ per cent. net upon the ordinary shares (against 5 per cent. for the preceding year), and carrying forward a balance of £1,876. 15s. 9d.

The Imperial German Government have, in virtue of their agreement entered into with the German-Norwegian Telegraph Company, taken over that Company, and will pay off the capital at par. This Company held virtually the whole of the capital, which is now being paid off. 95 per cent. of the amount has already been encashed, less exchange, and the balance, in accordance with German law, will be payable in the early part of next year. The sum repaid has been £66,956. The Directors have re-invested this capital in the following securities :—1,850 shares in the Western Union Telegraph Company, costing £31,482. 18s. 1d. ; 2,050 shares in the American Cable Company, costing £35,337. 11s. 2d. There remains a small balance still to reinvest.

In conformity with the Articles of Association the Marquis of Tweeddale and James Pender, Esq., two of the Directors, retire, and offer themselves for re-election. The auditors, Mr. John George Griffiths, F.C.A. (Messrs. Deloitte, Dever, Griffiths and Co.), and Mr. William Griffith, B.A., barrister-at-law, also retire at the meeting, and offer themselves for re-election.

Telephone Company of Austria (Limited).

The following is the Directors' report to be presented at the eighth ordinary general meeting of the Company, to be held at the offices, 53, New Broad-street, London, E.C., on Thursday, the 30th July, at four p.m. :—

The Directors have much pleasure in presenting to the shareholders their report and accounts for the year ending March 31, 1891.

There has been expended on capital account a further sum of £8,868. 7s. The gross receipts in Austria were £18,513. 14s. 0d. After providing for all expenses, including £4,418. 6s. 2d. for debenture interest and dividend on preference shares, and £3,520. 7s. 6d. for royalties and taxes to the Austrian Government, the profit on the year is £3,438. 16s. 2d., which, with the £1,047. 2s. 7d. balance from last year, gives a total of £4,485. 18s. 9d. to the credit of profit and loss account, which amount it is proposed to carry forward.

In view of the expiration in October next of some of the Company's concessions, negotiations with the Austrian Government as to the future of the Company have been in progress for a considerable time past. These negotiations are now approaching their final stage, and the result will be brought to the knowledge of the shareholders without delay. Under these circumstances your Board do not recommend at present the payment of any dividend on the ordinary shares.

The Directors have again to report a continued increase in the number of subscribers to the Company's exchanges, as shown by the following table :—

	No of subscribers.	Increase over previous 12 months.	Rental.	Increase over previous 12 months.
March 31, 1890...	2,652	..... 353	210,000fl.	..... 27,450fl.
March 31, 1891...	*3,023	..... 371	238,000fl.	..... 28,000fl.

* Exclusive of 240 "Extension" telephones, which give an additional rental of 8,210fl.

Installations in the towns are progressing at the usual rate, and, so far as the Board can judge, seem likely to continue. The calls of subscribers now average over 97,000 per week, as against 70,000 last year.

The thanks of the shareholders are again due to Dr. Eugen Weissel for his continued valuable services during the past year, and to Mr. Krause for the very satisfactory manner in which he continues to perform his duties as general manager.

Mr. Henry Grewing retires by rotation from the Board, but, being eligible, offers himself for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths and Co., also retire, but, being eligible, offer themselves for re-election.

Venezuela Telephone and Electrical Appliances Company (Limited).

The following circular has been sent to the shareholders, under date 20th July, 1891 :—I beg to inform you that the half-yearly interest on the debentures of this Company, due on the 31st inst., will be paid, on presentation of the Coupons, on and after that date, either in Amsterdam or at the Consolidated Bank (Limited), London.

It may afford you satisfaction to see the following figures, which point, as you will observe, to a steady growth of the Company's business since its incorporation, and to its success in the future.

The earnings have been as follows :—

	Gross.	Nett.
To December 31, 1890	£9,028	... £3,495
For month of January, 1891	1,120	... 500
„ „ February „	1,150	... 520
„ „ March „	1,210	... 520
„ „ April „	1,250	... 540
Estimated returns for May and June (the end of the financial year), based on the April returns	2,500	... 1,080
	£16,258	.... £6,655

The proportion of working expenses to gross earnings has been abnormally large during this period, owing to the fact that the works, during the whole of the year 1890 and up to the present time, have been under reconstruction and rearrangement.

It will be seen that, after providing for the debenture interest, which amounts to £3,500 per annum, and for the administration expenses in England, there will remain a considerable balance for dividend on shares.

The subscribers during the period above referred to have increased from 1,511 in April, 1890, to 2,092 in April, 1891 (viz., 1,721 connected up and 371 in course of being connected).

It is contemplated to increase the rental for the telephones, and as subways for underground wires have now been laid on a portion of the Company's system, there is every expectation of a considerable reduction in the working expenses in the future, which, together with the growing increase in the gross earnings, should add considerably to the profits in the current year, which commenced on the 1st inst.

Crompton and Co. (Limited).

The following is the third report of the Directors, to be presented at the annual general meeting of the shareholders, at the City Terminus Hotel, Cannon Street, in the City of London, on Wednesday, the 29th July, 1891, at 2: 30 p.m. :—

The Directors beg to submit to the shareholders the third annual statement of accounts and balance sheet made up to the 31st March last.

The business of the Company continues to increase, the order book is well filled, and negotiations are on foot for several important central station contracts, in addition to those at present in hand.

The Directors have given considerable attention to improved arrangements at the Chelmsford works for increasing the output, so as to ensure punctuality in the execution of orders. The fitting up of the London works, referred to in the Chairman's speech at the general meeting last year, has also been completed. These alterations and additions have entailed a rather heavy outlay on capital account.

Mr. J. F. Albright, one of the Managing Directors, has been on an extensive tour through Canada, the United States, Australia, India, and the Cape, visiting the different agents of the Company, and making arrangements which it is hoped will lead to a considerable extension of the Company's business abroad. The date appointed for the meeting of the Shareholders has been delayed to allow for Mr. Albright's attendance, on his return to England.

The net profits of the year amount to £13,030. 14s. 7d., and, after providing for the debenture interest and other payments set out in the revenue accounts, and deducting the interim dividends already paid on both the preference and ordinary shares, there remains, with the £474. 18s. 10d. brought forward from last year, a balance available for dividend of £6,484. 18s. 10d.

The Directors propose, after setting aside a sum of £500 as a provision for doubtful debts and contingencies, to declare a dividend of 3s. 6d. per share, making 7 per cent. per annum upon the preference shares, and 5s. 6d. per share, making, with the interim dividend, a total of 8 per cent. per annum upon the ordinary shares, carrying the balance forward.

Sir Charles Grant has retired from the Board, and the Directors have elected Mr. H. H. J. W. Drummond and Viscount Emlyn to fill this vacancy and that caused by the death of Viscount Torrington, mentioned last year. In accordance with the Articles of Association, Mr. B. Gibson retires from the Board of Directors by rotation, but offers himself for re-election. The auditors, Messrs. J. H. Duncan and Co., also offer themselves for re-election.

NEW COMPANIES REGISTERED.

JOSEPH EVANS AND CO. (LIMITED).—Registered with a capital of £10,000, in £5 shares. Object: To acquire the undertaking of Joseph Evans, of 118, Charles Henry-street, Birmingham, and to carry on thereat the business of tube manufacturers and manufacturers of and dealers in every variety of metal work.

ITALIAN ELECTRICAL LIGHT AND POWER COMPANY (LIMITED).—Registered by A. W. Rixon, 10, Austinfriars, E.C., with a capital of £60,000, in £4 shares. Object: to carry on every description of business connected with the generation, supply, and use of electricity for the purposes of light, power, or otherwise. The first subscribers are :—G. Taddei, 83, Via Arenula, Rome ; P. Alessandri, 92, Via dei Farnesi, Rome ; J. Reid, 101, Leadenhall-street, London ; C. E. Stuart, 4, Aberdeen-terrace, Highbury ; A. P. Windridge, 344, Stanstead-road, Catford ; T. Wholey, 7, Storey's-gate, S.W. ; J. Carr, 35, Paget-road, Stoke Newington. There shall not be less than three nor more than eight Directors ; the first are

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 689.—Vol. XXVII. FRIDAY, JULY 31, 1891. Price Fourpence.

NOTES.

A large and varied assortment of reasons can readily be marshalled up to account for the rapid development of electric traction in the United States, and its snail-like progress in the United Kingdom. If a reproduction of the results obtained with the electric cars on the Boston West End Railway could be guaranteed on this side of the Atlantic—and we know of no insuperable obstacle—even the most cautious of tramway directors might be induced to emerge from the "experimental stage." In Boston, according to our New York correspondent, electric traction costs nearly 10 per cent. less than horse traction per mile run, and its net earnings amount to over 77 per cent. more. Meanwhile, we in this country are still hammering away at battery traction, pending the advent of the perfect closed conduit.

The guarantee and maintenance of storage batteries, to which we referred last week, is not offered, as we stated, by the Electric Construction Corporation, but by the Foreign and Colonial Electrical Power Storage Company. It is really very difficult to bear in mind not only the new names under which old companies combine, especially when they are so very similar, but to remember who belongs to which. The Electric Construction Company was formed two years ago as the fusion of the well-known firm of Elwell-Parker with the Electrical Power Storage Company, the Foreign and Colonial E.P.S. Company being left out in the cold. But it seems that storage batteries and alternating dynamos do not run happily in parallel, and not only has the Elwell-Parker battery been given up, but the whole of the battery business is going to the Foreign and Colonial Company. This practically means that an electrolytic decomposition is about to take place; but the E.P.S. element cannot at present assume its old title, and the Foreign and Colonial branch has nominally come to life again to do the business at the old address and works of the E.P.S. The Corporation, would do well to resume the more easily remembered, and we may say more celebrated, name of Elwell-Parker.

While we strongly sympathise with Prof. Perry in his endeavour to simplify the confused and annoying systems of electromagnetic units, and while we feel sure that some simplification would be warmly welcomed by engineers, we regret that his suggestions were not made eight or ten years ago, when there would have been far less difficulty in effectually introducing them. We would gladly assist the matter by publishing the views of our readers, and hope that sufficiently convincing argument may be raised to overthrow the opposition which is sure to come from educational quarters. Electrical engineering has been regarded by certain advocates of the decimal system as a vulnerable point in the engineering profession a young and tender part, into which the thin end of the metric wedge may be thrust. Amid all the difficulties of mathematical theories the foreign flavour of the C.-G.-S. system is only a slight inconvenience to a student. He accepts the volt and ampere as a matter of course, but behind the watt lurks the erg and the dyne; he is taught to sneer at the foot pound, and to regard the horse-power as an antiquated convention. If he lingers long in the laboratory, and does not yearn for the vice and a job that he can hit with a hammer, and hit hard, he is likely to end by designing dynamos in centimetres, and to grumble at having to translate everything into the nearest inch measurement, with the result that the drawings bristle with thirty seconds, if not sixty fourths.

The C.-G.-S. system, as set forth in Everett's Units and Physical Constants, goes on merrily through mechanics, hydrostatics, strains and stresses, astronomy, sound, and light. It begins to falter in Chap. IX., on heat, when t has to appear, and again when Q turns up in the section on thermal conductivity, the dimensions of which are $k = Q/v_2 - v_1 \cdot x/At$, and this is after all only M/LT, or perhaps L^2/T; and when Joule's equivalent is arrived at, the student feels that the C.-G.-S. system is becoming strained. The next chapter on magnetism reveals unmistakably that whatever may have gone before, the arbitrary choice of units leads to very serious complications, and perhaps the one satisfactory point is, that the two conflicting systems of measurement have a ratio which appears to have a real existence as a "definite concrete velocity." The difficulty is, however, not entirely due to an attempt to force the C.-G.-S. system to adapt itself to quantities which will not fit it, but is brought about by the perfectly unwarrantable assumption that the specific inductive capacity of air, or of ether in air, is 1, and that at the same time the magnetic permeability, or μ, of air is also 1. Both these conventions cannot be true, and, as Dr. Oliver Lodge has pointed out, no one has the least right to suppose either true; but yet on these is built the purely artificial system of volts, ohms, farads, and the like. Conventions of this sort, especially when they lead to difficulties which obscure even simple calculations, are particularly obnoxious to the busy engineer. Prof. Perry has as much right to say that the μ of air is $17\frac{1}{2}$ as anyone else has to say that it is 1. But,

Digitized by Google

in suggesting that it shall be $4\pi \times 10^{-9}$, he removes at one stroke practically the whole difficulty of applying the C.-G.-S. system to practical engineering; and we do not hesitate for a moment to go further with him, and hope that, even yet, before it is too late, engineers will adopt the last four rules in his suggested system, and, for workshop and general engineering purposes, use inches, and thereby not only save themselves a great deal of extra work and time, but permit to enter the field that large contingent of engineers who are at present kept out by the serious complexity of the method of calculation.

Our excellent contemporary, the *Journal of Gas Lighting*, generally has something readable in its Electric Lighting Memoranda, and the conclusions at which the writer arrives are really creditable, considering the sources of information on which they appear to be based. One or two further hints would at times set him on the right track, and as the reasoning is always honest, a good deal more valuable information on electrical matters might be set before gas engineers than is done at present. This week's issue discusses the question, "When does it pay best to renew the lamps, knowing their price, efficiency, and the cost of current in every case?" "Electricians," says our contemporary, "connected with central stations are very shy of the subject," forgetting that the last batch of statistics was presented by Mr. F. Bailey. "It is marvellous," it continues, "that nobody seems willing to confess to being in possession of reliable data, obtained from experience, of what incandescent lighting of a definite quality actually costs in the United Kingdom, including everything." But the reason is very simple; we are waiting until competition in lamp manufacture begins. Until then, no arguments can possibly induce the present makers to divulge the figures which they alone can accurately give. It is not worth the while of any consumer to make not only elaborate records of life, but experiments on the relation between life and efficiency. Fierce competition may, however, be expected to bring these to light. Meanwhile, we run lamps at 4 watts to the candle because the makers recommend it, and no one suspects them of endeavouring to increase their trade by suggesting that their lamps should be over-run.

The *Journal of Gas Lighting* assumes that it will pay to throw a lamp away when it begins to "exhibit that lively appearance of a newly-blown-out wooden match," and it is quite possible that under some circumstances this might be the case, but though a certain make of lamp used to run down very much after 600 or 800 hours, the general experience with Edison-Swan lamps is that when they have run about 1,000 hours on the voltage for which they are marked, the filament suddenly gives way. In an article which will be found in another column, it is suggested that, at any rate in Paris, a lamp taking 3 watts per candle with a life of 500 hours, would be a great desideratum. A little arithmetic will show that with an eight candle lamp, taking (at 4 watts per candle) 32 watts, the energy for 1,000 hours at 7d. per unit comes to 18s. 8d., and with 3s. 9d. for the lamp, the total is £1. 2s. 5d. With 3 watts per candle the energy would come to 14s., and the cost of two lamps being added, the total is £1. 1s. 6d. In London, therefore, the difference is only 11d., and being spread over about two years, is not worth troubling about. To make the total cost in the two cases exactly equal the 3-watt lamps should have a life of about 467 hours. The American statistics recently published are of no use whatever to us, as, for the next two years or so, we are concerned only with one kind of lamp. It is possible that with cheap lamps it will be worth while in many cases to run them up bright, but the greater frequency of the sudden extinctions might become troublesome. Phenomenal lives are often recorded, but against these must be set the not uncommon cases of failure after a few hours.

Dover.—The tender of the Brush Company for the supply of the electric light is being discussed by the Town Council.

Trunk Wire Telephony in Germany.—The telephone trunk line connecting Stuttgart, Ulm, Augsburg, and Münich was opened to the public on July 1st, and was largely patronised.

Central London Railway Bill.—In the House of Commons, on Tuesday night, the Lords' Amendments to the Central London Railway Bill were considered and agreed to, and the Bill ordered for third reading.

Institution of Mechanical Engineers.—Among the works inspected by this Institution during its visit to Liverpool was the Liverpool Electric Supply Company's Works. This Company has now three central stations in operation.

The Utilisation of Water-power.—According to the *Elektrotechnischer Anzeiger*, the right to use a 60 H.P. water-fall, has been purchased by the town of Erding, in Bavaria, with the object of running a central station for electric lighting.

Glasgow.—Wednesday of this week was the last day for receiving applications for the new post of electric lighting engineer to the Corporation of Glasgow; and on that day there had been received somewhere about 50 such applications.

Stoke-on-Trent.—At the last meeting of the Town Council the Town Clerk was instructed to take steps to promote a Bill in Parliament enabling the Corporation to erect new gas works, and to supply electrical energy for public or private purposes.

The Late Mr. Willoughby Smith.—With reference to our note of last week regarding the funeral of Mr. Willoughby Smith, we are asked to mention that, in addition to the many friends named, the funeral was attended by over 100 of the staff and workmen of the firm of Messrs. Elliott Brothers.

Rule of Thumb.—A foreign observer defines the rule of thumb thus:—"You lift up a foot rule, place your thumb at zero, and move it along inch by inch until you think it is time to stop, a process known as 'thinking what to do' by some of the members of the engineering trade." It is a dangerous practice for amateurs.

The "Amber."—The Committee of the Royal Humane Society have conferred the medal for saving life on Mr. Robert Greey, commander of the Eastern Telegraph Company's steamship "Amber," for, "by presence of mind and good organisation and arrangements at the time, being the means of saving a number of lives on the occasion of the wreck of the 'Utopia.'"

Dublin.—Within the next four or five months some of the chief streets of Dublin are expected to be illuminated by electricity. The foundations of the central station buildings have been, by a piece of good luck, most admirably chosen, being on solid rock. The first streets to be lit up will be O'Connell-street, Westmoreland-street, College-green, Grafton-street, Dame-street, Parliament-street, Capel-street, Mary-street, Henry-street, College-street, and D'Olier-street.

Chicago Exhibition.—On Monday the Lord Mayor entertained the Chicago Commissioners at luncheon at the Mansion House.—On Tuesday the Commissioners waited upon Lord Cross, Secretary of State for India, and expressed their urgent

Digitized by Google

desire that the Indian Empire should be adequately represented. Lord Cross promised to communicate with the Viceroy on the subject. In the afternoon the Commissioners entertained a distinguished company at luncheon at the Savoy Hotel.

An Aluminium Steamboat.—An aluminium steamboat is now running on the Lake of Zürich. The boat weighs only about half a ton, viz., about half the weight of an ordinary boat of the same size. It was built at the works of Messrs. Escher Wyss and Co., of Zürich, the metal having been furnished by the Aluminium Works of Schaffhausen. The boat carries eight persons, and, with a 2 H.P. petroleum engine, easily makes six miles an hour.

York.—At the last meeting of the Streets and Buildings Committee of the City Council a report was received from Mr. Crompton, electrical adviser to the Corporation, relative to the projected introduction of the electric light. After the report had been fully discussed, the Electric Lighting Sub-Committee were instructed to visit Bradford and Newcastle, with the object of informing themselves as to the relative advantages of the high and low tension systems.

Bristol.—Last week the Electric Lighting Committee of the Town Council held a meeting for the purpose of receiving tenders for the preliminary works in connection with the electric lighting central station, but found that they had been practically boycotted by the trade. Instead of offers to undertake the work, they received a long list of objections to the provisions contained in the contract. The Committee appointed two members to confer with two representatives of the Master Builders' Association.

Thunderstorms.—A severe thunderstorm visited the south of England on Monday last. At the village of Lacy Green, near Princes Risborough, Bucks, while a flower show was in full progress, a heavy thunderstorm came on. Nine men were under a tree watching the operations of drawing a hive, when a flash of lightning struck the tree. Three of the men were killed, and three others were greatly injured.—At Lewes the race stand telegraph office was struck by lightning, set on fire, and destroyed.

Street Transformers.—The London Electric Supply Corporation recently gave notice to the London County Council of their intention to construct a street box in Coventry-street. The Company proposed to construct a pit, 5ft. square and 6ft. deep, with a cover in the footway about 2½ft. square, and to place two transformers therein, a cellar which had hitherto been used for this purpose being no longer available. The Highways Committee were of an opinion that such an interference with the public thoroughfares should not be sanctioned, and recommended the Council not to approve of the works.

Electric Haulage in Mines.—An electric haulage plant put in by Messrs. Crompton and Co. was inaugurated with some ceremony last week at Abercanaid, South Wales. The plant consists of compound condensing Marshall engine, and a 100 H.P., 500 volt, Crompton compound dynamo. From the generator sheathed cables are led under the road down the pit shaft, to a 50 H.P. motor situated about 800 yards from the pit bottom. This motor is series-wound, and runs at 800 revolutions. The power is transmitted from the motor by ropes to an intermediate shaft, to which the drums are geared by pinion wheels.

Engineering Department, Cambridge University.—Mr. W. E. Dalby, B.Sc. (Lond.), and Mr. C. G. Lamb, B.Sc. (Lond.), have been appointed Demonstrators in the Engineering Department of Cambridge University, under Prof Ewing. We understand that Mr. Lamb, who was a distinguished student and collaborateur of Prof. Ayrton's at the Central Institution, has been appointed with a special view to the development of teaching in applied electricity. The engineering laboratory, which is now taking shape, will include electrical engineering as one of its features.

Atmospheric Electricity.—Meteorological observatories are generally ill adapted, by reason of dust and smoke, for observations on atmospheric electricity; and, with the view of inciting private individuals to such work, Herren Elster and Geitel, of Wolfenbüttel, have lately issued a *brochure*, in which they indicate the ends to be sought and the instrumental means. Three things demand attention: first, systematic observation and measurement of electricity in the open air at different times in the day, humidity and air-temperature being determined at the same time; second, measurement of the fall of potential with a clear sky; and third, measurement of the fall of potential and its change of sign during rain, &c. The instruments and methods recommended are such as present little difficulty for private persons.

Electric Traction at Bremen.—The Bremen Strassenbahn Gesellschaft has contracted with the Thomson-Houston International Electric Company for the electrical equipment of two-thirds of their Bremen system. The line that was in operation last summer at the Exhibition is to be retained, and a further line of four miles is to be equipped with six motor cars and as many tow-cars as may be required. The Bremen Company proposes to work their system by electricity as soon as the first portion is ready. The Bremen Strassenbahn Gesellschaft is the first tramway company in Europe to purchase outright an electric tramway. It will be remembered that an electric line was run very successfully by the Bremen Tramway in connection with the Thomson-Houston International Electric Company last summer. From June 22nd to October 15th, 1890, 586,518 passengers were carried.

Cable and Land Line Interruptions and Repairs.—

Meteorological Telegrams.—The Pacific Postal Telegraph Company lately had a gathering of some 500 guests at the opening of a new telegraph office in San Francisco. After shortly describing the various instruments, the superintendent said he was often asked how long it took to telegraph to different places and get a reply. He would, therefore, now send telegrams to Portland, New York, Washington, Seattle, Tacoma, Canso (Nova Scotia), and London, inquiring about the weather. The first reply came from Portland in 3 minutes, "Weather fine"; the next from New York in 3 minutes 10 seconds, "Misty and warm"; Washington in 3 minutes 11 seconds, "Misty and warm"; Seattle in 3 minutes 21 seconds, "Misty and calm"; Tacoma in 3 minutes 28 seconds, "Misty, cool, and calm"; Canso (Nova Scotia) in 4 minutes 20 seconds, "Cold and misty"; while the answer "Misty and cold" came from London in 6 minutes 22 seconds.

A Combined Passenger and Freight Electric Tramway.—During the latter part of April a narrow-gauge electric railway, connecting the towns of Sissach and Gelterkinden, in Switzerland, was opened to traffic. The road is intended for both passenger and freight service, and accordingly differs in several respects from the various electric roads designed simply for passenger transportation. Its gauge is one metre, and its total length a little over two miles. For two-thirds of its length the road runs along the highway between the two towns; for the remainder of the distance a special roadbed had to be laid down. Power is supplied by a turbine plant located about half a mile from Sissach, and the dynamo, which is of the two-pole type, furnishes a current of 50 amperes at 500 volts. The current reaches the motor through an overhead line, the rails being used for the return circuit. The locomotive has two motors working independent axles through gearing, which reduces the revolutions of the axles to quarter of those of the motor shafts, which make 480 revolutions per minute. The speed ranges from 6¼ to 11¾ miles per hour.

Digitized by Google

Insulating Compositions.—Patents for insulating compositions are being taken out very freely just at present. Thus, in patent 11,130 (1890), it is proposed to saturate fibrous substances with a drying oil (preferably linseed oil, previously partially oxidised by heating for some hours with litharge or other suitable oxidising agent), and then drying. This process being gone through again and again until the substance has increased at least 50 per cent. in weight. Amalgamating rolls running at a high speed are then brought into play, until a smooth and homogeneous mass is obtained. Some 25 per cent. of gutta-percha or india-rubber is then added, and the mass subjected to the action of amalgamating rolls until it is capable of being formed into a block or rolled out into thin sheets. The fibrous substance may be wood fibre, hemp, flax, jute, cotton, or silk. The following recipe is given in patent 12,013 (1890):—Sulphur, 7lb.; clean pipe-clay, 1½lb.; slate dust, 1½lb.; paraffin wax, 2oz. The pipe-clay and the slate dust are to be thoroughly mixed by grinding under heat, the paraffin wax being then admixed, and the combination worked up to a paste. It is then, after exposure to become dry and hard, ground into a powder, and the sulphur mixed therewith.

Personal.—We have received from Messrs. William Notman and Son, of Montreal, a remarkably fine specimen of the photographic art in Canada in the shape of an excellent likeness of Mr. Frederic Newton Gisborne, the energetic and well known General Superintendent of Government Telegraphs for the Dominion of Canada.—Mr. J. F. Albright, Managing Director of Crompton and Co. (Limited), has just returned after a very successful tour round the world. He started originally with the Iron and Steel Institute for the United States, and then went to Australia to look after the business of the Crompton Electric Supply Company of Australia. After spending some months in various parts of Australia, he went to Ceylon, and from thence to Calcutta. After this he proceeded to Colombo and Mauritius, *en route* for Durban. Making this his headquarters, he went up country to Pretoria, where his Company is about to carry out the lighting of the town.—Mr. C. J. Robertson, who in 1887 installed and has since then superintended the glow lamp factory of the firm of J. Bondewijnse, Middelburg, Holland, has severed his connection therewith, and is now partner in, and Managing Director of, the firm of Latzko and Scharf, glow lamp manufacturers, Vienna.

Gas Engines and Electric Light Installations.—"Having to inspect an arc and incandescent installation at Lille, supplied with current from a dynamo driven by a gas engine, I was able," says M. Witz, in a recent note in the *Comptes Rendus*, "to compare the quantity of gas consumed in this manner with that previously consumed by the lamps and regenerative burners employed in the illumination of the same locality. Some 16 arcs and 71 16 c.p. glow lamps replaced six powerful double regenerating See lamps, 91 ordinary, and 19 batswing burners. The electric lamps gave 15 per cent. more light than the gas lamps, a fact I was able to ascertain by comparative measurements of the illumination of the floor surface, and, in addition, they lit up a few places where there had not previously been any gas lamps. Now, things being so, the gas engine only consumed 21,500 litres (752 cubic feet) per hour, whilst the gas lamps consumed 26,500 litres (927 cubic feet). Thus, when we employ gas as the motive power for driving a dynamo supplying current to electric lamps we consume 17 per cent. less gas than we should if we burnt the gas at the burners, and we obtain much more light."

A Thousand Horse-Power Dynamo.—A somewhat peculiar dynamo for metallurgical work has recently been completed for the Willson Aluminium Company, of New-York. The machine is unusual, not only in size but in general construction, being a decided return to the early Gramme type. The frame of the machine consists of two massive castings, with salient pole pieces having wrought-iron cores both above and below the armature. The armature itself is 24in. in diameter, and 47in. long, and is formed upon a 5in. hammered steel shaft, resting in composition bearings 15in. long. The armature weighs 6,163 pounds, while the frame contains 11,000 pounds of castings and 7,000 of solid forgings. As the machine stands, with its present pulley, it weighs a little less than 30,000 pounds. The armature is a Gramme ring, with conductors formed of solid drawn copper, with a cross section of three square inches; the bars upon the periphery are rigidly bolted in place, and insulated from each other. The brushes are made to bear directly upon the armature. The designer estimates that the machine will have an output of 750,000 watts, if necessary. During tests recently made no heavy current was drawn from the machine, but when running on open circuit the heating of the armature was said to be so slight as to render it evident that Foucault currents and hysteresis were not formidable factors in its general efficiency, a rather surprising result with solid bar conductors.

The Capacity and Self-Induction of Overhead Telegraph Lines.—In a recent note in the *Comptes Rendus*, M. Massin calls attention to the lack of data with regard to the capacity and self-induction of overhead telegraph lines, caused by the difficulty of making the necessary measurements owing to the proximity of "live" wires. M. Massin, however, found means for obtaining these data for three circuits. A line, 18 kilometres long; iron wire, 3mm. in diameter; two wires about 40 centimetres apart, and 4·5 metres from the ground. B line, 50 kilometres. C line, 50 kilometres; copper wire 2·5mm. in diameter; two wires about 50 centimetres apart, and 5·5 metres from the ground. The following results were obtained:—

Line.	Kilometric capacity in microfarads with respect to earth.	Ditto of the looped wires.
A	·0097	·0070
B	·0099	·0069
C	·0092	·0065

The two wires have, therefore, when looped, seven-tenths the capacity of either separately. On underground lines the capacity is exactly halved. The coefficients of self-induction per kilometre of looped wire were found to be as follows:—Line A, ·0121 henrys; line B, ·0129 henrys; line C, ·0025 henrys.

The London County Council and Electric Lighting.—In the report of the London County Council for the year ending March 31, 1891, it is stated that a meter-testing station, with the necessary appliances, has been established by the Council at Nos. 42 and 43, Cranbourne-street, and an inspector has been appointed. A person has also been selected to act as caretaker of the station and to assist the inspector. The rent value of the premises, which are the property of the Council, is £240 a year; £717 has been expended in necessary alterations and repairs to fit them for the purposes of an electric meter-testing station; and the amount expended up to the present time for the apparatus required for testing is £1,012. It is expected that the station will shortly be in full working order. The Council has, since the date of the last annual report, received and dealt with 123 notices, many of which referred to works extending over large areas; and each of these has been separately considered, and, where necessary, special conditions have been attached to the Council's consent to such works. The Council has, during the year, sanctioned the laying of no less than 137½ miles of mains in streets and roads, in addition to innumerable service lines to particular consumers. Of these mains, 86½ miles were for currents of high tension and 51 miles were for currents of low tension. The Council has in all cases required that the mains should be laid under the footways wherever it was found practicable to do so, and that the covers of the street-boxes should consist of iron frames filled in with material to suit the paving. In consequence of an accident to two persons, in November last, through high-tension mains having, on account of defective insulation, come in contact with the cover of a street-box, the Council has, after communication with the Board of Trade, required in cases where high-tension mains are used, that each of the street-boxes shall be provided with an inner as well as an outer cover, the two to be insulated from each other as far as practicable, and that the outer cover shall be efficiently connected to earth, or that other adequate precautions shall be taken to prevent risk of accident through defective insulation. An official is employed to inspect the works of the companies in the public streets in order to see that the requirements of the Council are complied with.

ELECTROMAGNETIC THEORY.—XIII.

BY OLIVER HEAVISIDE.

(*Continued from page 296*).

§ 73. We may now consider the practical meaning of the stress whose relation to the electric and magnetic forces has, under certain suppositions, been formularised. Go back to the foundation of electromagnetic theory, viz., the mechanical forces experienced by electrically charged bodies, by conductors supporting currents, and by magnets, intrinsic or induced. It is by observation of these forces in the first place, followed by the induction of the laws they obey, and then by deductive work, that the carving out of space into tubes of force follows; and now, further, we see that the localisation of the stored energies, according to the square of the electric and magnetic force respectively, combined with the two circuital laws, leads definitely to a stress existing in the electromagnetic field, which is the natural concomitant of the stored energy, and which is the immediate cause of the mechanical forces observed in certain cases. But the theory of the stress goes so far beyond experimental knowledge in some respects, although agreeing with it in others, that we could only expect it to be true if the theoretical foundations were also rigidly true in all respects. Such is not the case, however. To begin with, the way of expressing the action of ordinary matter merely by altering the values of the two ether constants, and by a fresh property, that of conductivity, is extremely bald. It is, indeed, surprising what a variety of phenomena is explained by so crude a method.

The objection is sometimes made against some modern theoretical developments that they are complicated. Considered as an argument, the objection is valueless, and only worthy of superficial minds. Whatever do they expect? Do they not know that experimental knowledge, even as at present existent, shows that the theory of electromagnetism, when matter is present, must, to be comprehensive, be something far more (instead of less) complicated than theory as now developed? The latter is, as it were, merely a rough sketch of a most elaborate subject, only small parts of which can be seen at one time.

In the next place, even if we take the stated influence of matter on the ether as sufficient for the purposes of a rough sketch, the theory of the stress should, except in certain relatively simple cases, be received with much caution. Why this should be so will be apparent on examining the manner in which the stress has been obtained from the circuital laws. If we investigate the subject statically, and, starting from certain mechanical forces regarded as known, endeavour to arrive at a stress which shall explain those forces, we shall find that the problem is essentially an indeterminate one. All sorts of stress functions may be made up which are precisely equivalent in their effects in the gross, that is, as regards translating or rotating solid bodies placed in an electric or magnetic field. To remove this indeterminateness a dynamical method must be adopted, wherein what goes on in the unit volume whilst its electric and magnetic states are changing, and the matter concerned is itself in motion, are considered. If our system of connections is dynamically complete and consistent, and is such that the flux of energy can be traced, then a determinate stress comes out, as we have found. The method is, at any rate, a correct one, however the results may require to be modified by alterations in the data. Besides that, the distribution of energy (electric and magnetic) in bodies is in some cases open to question; and a really speculative datum is that concerning the motion of the ether as controlled by the motion of matter. Now, this datum appears to be one which is essential to the dynamical method; the only alternative is the statical and quite indeterminate method. Our attitude towards the general application of the special form of the stress theory obtained should, therefore, be one of scientific scepticism. This should, however, be carefully distinguished from an obstinate prejudice founded upon ignorance, such as is displayed by some anti-Maxwellians, even towards parts of Maxwell's theory which have received experimental demonstration.

The stress theory can, nevertheless, sometimes be received with considerable confidence, if not absolute certainty. The simplest case is that of ordinary electrostatics.

§ 74. Let there be no magnetic force at all, and the electric force be quite steady, and the medium be at rest, and there be no impressed forces. These limitations bring the circuital laws down to

$$0 = k\mathbf{E}, \quad \ldots\ldots \quad (1)$$

$$-\operatorname{curl}\mathbf{E} = 0; \quad \ldots\ldots \quad (2)$$

that is, there must be no conduction current anywhere, and the voltage in any circuit must be zero. The first condition (1) implies that there is no electric force in conductors. We may, therefore, divide space into conducting and non-conducting regions, and our electric field is entirely confined to the latter. The second condition (2) implies tangential continuity of **E** at the boundary of the non-conductor, so that as there is no **E** in the other or conducting side, there must be no tangential **E** on the non-conducting side. The lines of force, therefore terminate perpendicularly on the conducting matter. Whether the conductors are also dielectrics or not is quite immaterial. The displacement also terminates normally on the conducting surface in the usual case of isotropy. Thus D, the tensor of **D**, measures the surface density of electrification, when the positive direction of **D** is from the conductor to the insulator. But in general it is the normal component of **D**, that is **DN**, where **N** is the unit normal vector, that measures the density of the electrification. Besides this, there may be interior electrification of the non-conductor, its volume density being measured by the divergence of the displacement. The arrangement of the electric force, so that the circuital voltage shall be zero throughout the non-conductor, and give the proper internal electrification, and the charges on the conductors, is uniquely determinate.

We have thus the ordinary case of a number of charged conductors in air, with the difference that the air, or parts thereof, may be replaced by matter of different permittivity. It is also to be noted that one non-conducting region which is entirely separated from another by conducting matter may be taken by itself, and all the rest ignored.

Now, first without replacing the air by matter of different permittivity, we see that there are two entirely different ways of considering the mutual actions of the conductors. The old way is analogous to Newton's way of expressing the fact of gravitation. We may say that any element of electrification ρ repels any other ρ' with a force

$$\rho\rho'/4\pi cr^2$$

if r be the distance between the two charges, and that the resultant of all such forces makes up the real forcive.

In the other way, appropriate to the philosophy of Faraday, as developed by Maxwell, these forces acting at a distance are mathematical abstractions only, and have no real existence. What is real is a stress in the electric field, of a peculiar nature, being a tension of amount U parallel to **E**, combined with an equal lateral pressure, and it is the action of this stress that causes the electrified conductors to move, or strains them, according to the way they are supported, when by constraints they cannot appreciably move.

Since the electric force is normal to the conducting surfaces, the stress vector is entirely a normal pull of amount U per unit area, and the motions or tendencies to move of the conductors are perfectly accounted for by this pull. They do not move because of electrical forces acting at a distance across the air, but because they are subjected to moving force on the spot by the stress terminating upon them.

Thus a charged soap-bubble is subjected to an external radial tension, and therefore expands; and so, no doubt, does a charged metal sphere to some small extent. The parallel plates of a condenser are pulled together. When they are very large compared with their distance apart, the force on either is

$$\tfrac{1}{2}\,\mathrm{E}\,\mathrm{D} \times \text{area},$$

$$= \tfrac{1}{2}\,\mathrm{E} \times \text{charge}.$$

Here E is the transverse voltage divided by the distance be-

Digitized by Google

tween the plates, so that, if the plates be connected to a constant source of voltage, the attraction varies inversely as the square of the distance between them; whereas, if the plates be insulated and their charges constant, the attraction is the same at any distance sufficiently small compared with the size of the plates.

But by sufficiently separating the plates, or by using smaller plates, the displacement, which was formerly almost entirely between them will spread out, and will terminate in appreciable amount upon the sides remote from one another. By the pull on the remote sides thus produced the attraction will be lessened, and the further the plates are separated the more displacement goes to their backs, and the less is the attraction. When the distance is great enough it tends to be simply the attraction between two point charges. Thus the attraction between two distant oppositely charged conducting spheres, which varies closely as the inverse square of the distance, depends entirely upon the slight departure from uniformity of distribution of the electrification over their surfaces, whereby the normal pull on either is made a little greater on the side next the other than on the remote side. Also, the inverse square law itself, which is exactly true for point charges, is merely the ultimate limit of this operation.

Some attacks have been made on the law of inverse squares, especially in its magnetic aspect. But these attacks appear to have been founded upon misapprehension. The law is true, and always will be.

§ 75. In the above electrostatic application of the stress, it will be observed that the tension alone comes into play, at least explicitly, owing to the tubes of displacement terminating perpendicularly on the conductors. Thus each tube may be compared with a rope in a state of tension, pulling whatever its ends may be attached to. But the lateral pressure is needed to keep the medium itself in equilibrium, so that the only places where translational force arises from the stress is where there is electrification. The mechanical force is

$$\mathbf{F} = \mathbf{E}\,\mathrm{div}\,\mathbf{D} = \mathbf{E}\rho \quad . \quad . \quad . \quad . \quad . \quad (3)$$

per unit volume. This is the force on volume electrification, and is the result of the differential action of the stress round about the electrification, as in the case of the inverse square law between point charges, lately mentioned. The corresponding surface force is

$$\mathbf{F} = \tfrac{1}{2}\,\mathbf{E}.\mathbf{DN} = \mathbf{N}U \quad . \quad . \quad . \quad . \quad , \quad (4)$$

per unit area. Now, here **DN** is the surface equivalent of div **D**, so there is at first sight a discrepancy between the expressions for the force per unit volume (3), and per unit area (4), on bodily and surface electrification. How the coefficient $\frac{1}{2}$ comes in may be seen by taking the limiting form of the previous expression. Let there be a thin skin of electrification, of amount σ per unit area; **E** falling off from **E** outside to 0 inside the skin. Evidently the mean **E** is $\frac{1}{2}$**E**, so that the total force on unit area of the skin obtained by summation of the forces on the volume electrification in the skin, is not $\mathbf{E}\sigma$, but $\frac{1}{2}\mathbf{E}\sigma$. This is merely a mathematical harmonisation. From the point of view of the stress the difficulty does not present itself.

The harmonisation is simply evident when the layer is of uniform density, for the electric force will then fall off in intensity uniformly. It might, however, be suspected that, perhaps, the result would not come out quite the same if we assumed any other law of distribution, and kept to it in proceeding to the limit by making the skin infinitely thin. But a cursory examination will show that it is all right; for if **E** is the electric force within the layer, the electrification density will be $c\,(dE/dx)$ and the translational force will be $c\mathbf{E}\,(dE/dx)$ per unit volume, if x is measured perpendicularly to the skin's surfaces. Integrate through the skin, and the result is

$$F = \tfrac{1}{2}\,cE_1^2 - \tfrac{1}{2}\,cE_2^2 = U_1 - U_2,$$

where the suffixes refer to the value just outside the skin, on its two sides. In the present case the second term U_2 is zero (within the conductor), so that the result is the single normal pull of the tension on the non-conducting side.

§ 76. In this connection the old question of the depth of the layer of electrification on a conducting surface crops up. Has it any depth at all, and, if so, how much? The question is not so superficial as it looks, and the answer thereto lies in the application thereof. If a powerful mental microscope be applied to magnify the molecules and produce evident heterogeneity, the surface of a conductor would become indefinite; and unless the molecules were found to be very closely packed, it is evident that the displacement in the ether outside the conductor would not terminate entirely upon those molecules which happen to be most superficially situated, but that a portion of the displacement would go deeper and in sensible amount reach molecules beneath the first set, and an insensible amount might penetrate through many layers. Thus in a molecular theory the depth of the layer of electrification has meaning, and could be roughly estimated.

But the case is entirely different in a theory which deliberately ignores molecules, and assumes continuity of structure. A conductor is then a conductor all through, and not a heterogeneous mixture; and the surface of a conductor is an unbroken surface. The electrification on it is therefore surface electrification, and has no depth. For it to be otherwise is simply to make nonsense. It is desirable to be consistent in working out a theory, for the sake of distinctness of ideas; if, then, we wish to give depth to surface electrification, and still keep in harmony with Maxwell's theory, we must change our way of regarding a conductor, and bring in heterogeneity. Each view is true, in its own way; but as in the mathematical theory continuity of structure is tacitly assumed, we have a simultaneous evanescence of one dimension in the distribution of electrification.

The same question occurs in another form in the estimation of bodily electrification, when the meaning of volume density of electrification is considered. When air is electrified, it is probable that the electrification is carried upon the foreign particles suspended in the air, and it may be partly upon the air molecules themselves. In either case it is ultimately surface electrification, and quite discontinuous. But, merely for the sake of facility of working, it is desirable to ignore all the discontinuity, and assume a continuous and practically equivalent distribution of bodily electrification. Thus, as previously we saw surface density to be a kind of volume density, so now we see that volume density is a kind of surface density. When, therefore, we say that the translational force per unit volume is $\mathbf{E}\rho$, where **E** is the electric force and ρ the volume density of electrification, we really mean that $\mathbf{E}\rho$ is the average, obtained by summation, of the translational forces on the multitudinous electrified particles, every one of these forces being itself a differential effect, as before seen, viz., the resultant of the unequal pulls on different parts of a particle exerted by the electric stress.

As ether has some of the properties of matter, and as electrification is found in association with matter, it is possible, however improbable, that ether itself may become electrified. But of this nothing is known. Nor, more importantly, is it understood why the electric stress appears to act differently on positive and on negatively electrified matter. But, if we begin to talk about what is not understood, we enter illimitable regions. Men who are engaged in expounding practical problems sometimes make the boast that they take and discuss things as they are, not as they might be. There is a sound of specious plausibility here, which is grateful and comforting; but, as a matter of plain fact, questions of physics never are theorised upon as they are, but always as they might be. It is a necessity to limit the field of inquiry, for to take things as they are, or as they seem to be, would lead at once to a complete tangle. For the problem, as it presents itself in reality, there is always substituted a far simpler one, containing certain features of the real one emphasised, as it were, and others altogether omitted. The juveniles, who take things as they are, do not do it; they only think so. They may strain out a few gnats successfully, but swallow, quite unawares, all the camels in Arabia. But the principle and practice of limitation and substitution is the same all over; in politics, for instance, where a fictitious British Constitution does brave duty, as a scarecrow, and in other useful ways.

PRACTICAL ELECTRO-MAGNETIC UNITS.

BY PROF. JOHN PERRY, F.R.S.

SIR: This note was written some years ago, and has been brought forward at various meetings of the British Association Committee on Electrical Standards. The author, to quote his own words, sees so many disadvantages as well as advantages in the system proposed that he begs that the note may be published and discussed by practical men before any steps are taken by the Committee. I should be glad if, in accordance with his wishes, you could insert it in *The Electrician*.—Yours faithfully,

R. T. GLAZEBROOK,
Secretary Electrical Standards Committee of the British Association.

Men who use the ohm, ampere, and volt in their electric calculations object to the conversion of these to C.-G.-S. units when making calculations on the magnetic circuit of the dynamo-machine or of transformers and other electro-magnetic contrivances. It results that new and ill-defined systems of units are getting into use. There are "Kapp" lines of magnetic force to the square inch, for example; many scientific men, acquainted with workshop methods, are already using C.-G.-S. lines per square inch.

It is with great diffidence that I make the following suggestions. When my students make calculations on the mechanical design of electric machines they use the inch as the unit of length, and the weight of one pound in London, as the unit of force. When they make calculations on the electric and magnetic circuits of the same machines they use 1cm. as the unit of length, and the watt as the unit of power. I have found that they do not object to these systems, and, with all due deference to members of the Committee who would insist on the general use of C.-G.-S. units even in mechanical engineering, I beg to say that the inch and pound must continue to be used by my students in their machine design,* and if I make any alteration it will rather be to use 1in. as my unit of measurement in making electro-magnetic calculations, than to use C.-G.-S. units in my practical mechanical engineering work. In what follows I will assume that practical men do not object to the use of the centimetre as a unit of length in making electro-magnetic calculations.

At present:—

I. A wire 1cm. long, moving with a velocity of 1cm. per second across unit (C.-G.-S.) field, generates the unit E.M.F. or 10^{-8} volt.

II. If a wire moving across unit field at 1cm. per second is conveying unit current (10 amperes), the power used (or developed) per 1cm. of its length is one erg per second (or 10^{-7} watts).

The integral of the magneto-motive force all round any elementary solenoid in a magnetic circuit is obtained by dividing the current turns (the unit current turn is 10 ampere turns) by 4π. We see, then, that in dealing with the magnetic circuit of a dynamo machine, and in dealing with transformers, in dealing with the induction produced by currents or with electromotive forces produced by induction, whether by movements of coils in magnetic fields or by variable magnetic fields, or by both together, we find at present, that if the ohm, ampere, volt, and watt are our electric units, then $4\pi/10$ or 10^8, or $4\pi \times 10^{-9}$, enters into most of the mathematical expressions, either as a multiplier or divisor. Just at present, the calculations involve other complications, because the true ohm, ampere, and volt are not in practical use.

I would suggest that the practical unit of magnetic flux (or induction or force), be 10^8 C.-G.-S. units, and that it receive a name. That the magnetic permeability of air shall no longer be assumed to be unity, but, in the practical system of measurement, be tabulated like the permeability of any other substance; —the permeability of air will be $4\pi \times 10^{-9}$, and that in future no substance shall have unit permeability. That the unit of total magnetomotive force in a magnetic circuit be 1 ampere turn. The unit of magnetomotive force gradient would be 1 ampere turn per centimetre. It will follow that:—

I. A wire one centimetre long, moving at 1cm. per second across unit field, generates an E.M.F. of 1 volt.

II. If a wire 1cm. long conveys 1 ampere, the power used (or developed) in moving it across the unit field at 1cm. per second is 1 watt.

III. A magnetomotive gradient of one ampere turn per centimetre produces unit induction (magnetic flux or force) per square centimetre if the permeability is 1.

IV. Change of induction (magnetic flux or force) at the rate of one unit per second produces 1 volt per turn of wire.

If it were allowable to use 1in. as the unit of length, and this would delight every electrical engineer in English-speaking countries, we can, by altering the above units, have all our rules quite simple, such as:—

I. A wire 1in. long, moving with a velocity of 1in. per second across unit-field (per square inch) generates the E.M.F. of 1 volt.

II. If a wire moving across unit-field at 1in. per second is conveying 1 ampere, the power used or developed per inch of its length is 1 watt.

III. The integral of the magnetomotive force all round any elementary solenoid in a magnetic circuit is exactly the number of ampere turns.

IV. Change of induction (magnetic flux) at the rate of one unit per second produces 1 volt per turn of wire.

* No man can think and design in two distinct sets of units. The mechanical engineer must either use the units so universally employed in workshops and engineering societies, or else the C.-G.-S. units. He cannot habitually use both. When a student enters workshops he is already frightfully handicapped by the mere fact that he has been to college, for there is still a great prejudice among practical engineers against education and "book knowledge." The professors who talk so glibly about the absurdity of teaching students in the ordinary units, and who insist on C.-G.-S. units, have no conception of the martyrdom to which they would devote a poor apprentice, who will in any case find himself in a sufficiently difficult position when he enters the shops. I do not deny that French is a more beautiful language than Chinese, but if I were sending a man to China to spend his life among Chinamen, I would not insist on his having a knowledge of French, and I would especially object to his being taught to ridicule and altogether neglect the Chinese language.

NOTES ON PERMANENT MAGNETS.—III.*

BY PROF. SILVANUS P. THOMPSON, F.R.S.

Methods of Magnetising.—The ancient methods of magnetising, including "single-touch," "double-touch," "divided-touch," "circular touch," in all their varieties may be dismissed as obsolete. The only methods needing attention are those based upon the use of electric currents. Arago discovered this way in 1820, and magnetised steel needles by inserting them within a spiral coil connected to a voltaic battery. Elias, of Haarlem, in 1844, proposed a useful variation of this process. Instead of winding the wire in a long tubular spiral, he coiled it in a compact ring of many layers, which could be slipped loosely over the piece of steel which was to be magnetised, and then moved along it from end to end, so as to bring every part successively into an intense magnetic field. In 1846, Böttger suggested a modification for special application to horse-shoe magnets, consisting of two coils oppositely wound, to be slipped over the two polar ends simultaneously. Sinsteden used, for magnetising horse-shoe forms, a powerful two-pole electro-magnet, against the polar ends of which the steel horse-shoe was placed, and while thus *in situ*, stroked the horse-shoe in the direction from bend to poles with an armature of iron resting across the two limbs. Van der Willigen, in his remarkable treatise† on the Haarlem magnets forged by Van Wetteren, describes the method used for these famous magnets. The steel horse-shoe is placed with its poles against the pole-pieces of a Ruhmkorff's electro-magnet, and the current from ten or twenty Bunsen cells is then turned on and off three or four times. The current being cut off, the horse-shoe is then raised into a vertical position, and the keeper is slid across its poles

* Parts I. and II., *The Electrician*, July 3 and 10.

† Van der Willigen. *Sur le Magnétisme des Aimants artificiels.* (Archives du Musée Teyler, Haarlem, Vol. IV., 1878.)

Digitized by Google

before these are removed from contact with the electro-magnet. The magnet is then in a super-saturated state, holding on to its keeper with a pull about 30 per cent. greater than the permanent pull which it will exhibit. For larger magnets, Van der Willigen made a simultaneous use of the Ruhmkorff electro-magnet as described, and of an Elias's ring, which he slid to and fro from one end to the other of the horse-shoe, from 20 to 100 times, whilst the electro-magnet was also in action.

For small bar magnets and compass-needles it suffices to draw them over the poles of a large electro-magnet, each extremity of the piece of steel being finally touched against the pole of opposite kind, and pulled off normally. For straight bars of considerable size, Van der Willigen used the same electro-magnet, adjusting the distances between the polar faces to correspond to the bar to be magnetised, and then applied the same process as for horse-shoes, but, of course, without applying a keeper.

One process, known as Hoffer's method, consists in stroking the steel horse-shoe from the poles to the bend with an iron rod laid across the limbs, whilst it is in contact with the poles of another previously-magnetised horse-shoe. Van der Willigen, who examined this method, found it faulty and even harmful. It set up inequalities in the distribution of the magnetism, and diminished the effective power of magnets previously magnetised as described above.

Another process, which has been suggested at various times as an improvement on the ordinary processes, is to subject the magnet to powerful magnetising forces during the act of hardening. Robinson placed the steel bars red hot against the poles of a strong magnet, and in this position applied cold water to the bar. Holtz says that thick steel bars so magnetised during sudden cooling are twice as powerful as those magnetised in the cold; and that thin bars are three times as powerful. Aimé and Hamann have also advocated this method; which, however, does not seem to have any real advantages.

Moser, in 1838, made a comparative trial of various methods, as applied to a parallelopipedal steel rod weighing 12 ounces. He measured the degree of magnetisation by the method of oscillations, observing the time required for one complete swing. From the duration of the oscillation the relative strengths are calculated. The results of eight methods, each better than the preceding, are given as follows :—

—	Time of one swing. (sec.)	Relative strength.
1. Knight's method of "divided-stroke," using two permanent magnets; 20 strokes on one side of rod only	22·13	1
2. Same, repeated on all four sides	14·87	2·21
3. Same, repeated with masses of iron laid under each end of the bar	14·63	2·29
4. Same, repeated while bar placed on top of a reversed steel magnet	12·13	3·33
5. Mitchell's method of "double-stroke," using two separate steel bar magnets	11·13	3·95
6. Same, using a steel horse-shoe	10·19	4·71
7. Aepinus' method of "circular-stroke," using same horse-shoe magnet	8·75	6·39
8. With an electro-magnet: rod laid on two iron pole pieces on the poles of the electro-magnet, and while here stroked with steel horse-shoe; the current of the electro-magnet then turned off, and rod then lifted off	8·0	7·62

These experiments leave no doubt as to the superiority of the modern method over the ancient ones.

Constancy of Magnets.—It by no means follows that the magnet which shows the greatest amount of permanent magnetism will be the most constant in its retention of the same. Magnets lose their magnetism from many causes, such as accidental shocks, contacts with other magnets or pieces of iron, changes of temperature, slow annealing of the steel, and the like. The relation of these influences to the quality and temper of the steel, and to the dimensions of the magnet, are not very well known, but some information exists.

Gray,* using glass-hard magnets, found the percentage of loss of magnetism due to a small demagnetising force (that of unit field) to vary widely for magnets of different lengths. A bar (10 diameters long lost 0·8 per cent.; one 20 diameters long lost 0·6 per cent.; 40 diameters long, 0·5 per cent.; whilst one 100 diameters long lost about 0·44 per cent.

Bosanquet† using a considerable number of magnets made (on February 8th, 1885) from the best cast steel, as hard as they could be made, found the following fall in magnetic moments :—

February 18.....12,539	March 15 11,767
March 3.....11,822	April 6 11,620
September 18.....11 119	

Lamont‡ made an investigation, lasting eleven years, as to the constancy of the magnets used in the Observatory at Munich for the daily magnetic measurements. These magnets had already been repeatedly alternately immersed in warm and cold water, but had not attained by this process a state of constancy, as the following figures show. The losses are given in decimal parts of the whole magnetic moment :—

——	1848.	1849.	——	1848.	1849.
January	0·0000	0·0000	July	0·0028	0·0016
February.....	0·0003	0·0001	August	0·0032	0·0022
March	0·0003	0·0002	September ...	0·0028	0·0022
April	0·0008	0·0005	October	0·0017	0·0013
May	0·0014	0·0007	November ...	0·0009	0·0007
June	0·0022	0·0011	December ...	0·0005	0·0001

The total decrease in various years, also in terms of the whole magnetic moment as unity, was as follows :

1847	0·0174	1853	0·0099
1848	0·0169	1854	0·0103
1849	0·0103	1855	0·0081
1850	0·0091	1856	0·0099
1851	0·0113	1857	0·0071
1852	0·0079	1858	0·0063

According to Barus,§ mean atmospheric temperature, acting on freshly quenched steel for a period of *years*, produces a diminution of hardness (with consequent loss of permanent magnetism) about equal to that which would be caused by the action of a temperature of 100°C. acting for a similar period of *hours*.

Some persons have sought to explain the slow decay of magnetism by reference to chemical changes of the surface due to oxidation, moisture, &c., and have proposed to prevent such decay by gilding, silvering, or lacquering the surface of the magnet. Such remedies are entirely ineffectual, and the supposition on which they are based is erroneous.

Cheesman observed the percentage loss of magnetism caused by percussion, the magnets being allowed to fall from a height, with the following results :—

Brand and temper.	Height of fall in metres.	Percentage loss of magnetism.
Steel wire, soft	1·5	30
,, ,, mechanically hardened	2·0	44
,, ,, ,, ,,	3·0	57
Steel rod, mechanically hardened	2·0	52
,, ,, ,, ,,	7 times, do.	81
Iron wire, mechanically hardened	2·0	84
,, ,, ,, ,,	3 times, do.	95
,, ,, soft	2·0	83
,, ,, ,,	3·0	99
Iron rod, soft	2·0	97
Steel wire, glass hard	3·0	6
,, ,, ,,	3·0	4

W. Brown,* using magnets made from silver steel, all 10 centimetres long, endeavoured to find a relation between the temper of the magnets and the percentage loss of magnetism due to percussion after the magnets had been laid aside for various periods of times. His results are embodied in the following table, from which it will be seen that the glass-hard temper appears to be the most constant in this respect. It is less certainly shown that long magnets are more constant than short ones.

Temper.	Diameter ratio $\frac{\ell}{\delta}$.	Specific magnetisation σ.	Loss per cent. due to percussion after lying aside for				
			1 hr.	20 hrs.	44 hrs.	1 mth.	3 mths.
Glass-hard...	33	41	1·98	2·0	1·95	1·04	0·8
„ „	50	45	2·96	3·2	1·48	1·00	0·0
Yellow	33	44	6·03	6·1	4·8	5·4	6·2
„	50	46	4·0	3·5	3·76	2·6	4·0
Blue	33	54	11·8	10 8	9·71	11·8	7·5
„	50	71	8·2	8·2	8·18	7·5	8·7

Strouhal and Barus, who have made so many researches upon the physical properties of steel, have examined the question of magnetic constancy in relation to form, temper, and exposure to fluctuations of temperature. They found that a glass-hard magnet, 119 diameters long, lost 30 per cent. of its magnetism when heated for six hours in steam at 100°C, but the same magnet, when re-magnetised, and again heated in steam, now only lost 5·3 per cent. The loss of magnetism on the first heating was found to vary in magnets of different lengths.

A magnet of 119 diameters' length lost 30 per cent.
„ 108 „ „ „ 28 „
„ 35 „ „ „ 49 „
„ 14 „ „ „ 67 „

In every case after protracted heating in steam, a condition was attained in which neither the specific magnetisation nor the specific resistance (*i.e.*, the hardness as measured electrically) showed any appreciable further change. These investigators came to the conclusion that magnets so treated possess a special fixidity; and resist not only changes of temperature but mechanical shock, better than magnets prepared in any other way. As an example, they took a short magnet 2·5 centims. long, 0 4 centims. wide, and 0·3 centims. thick. This was boiled in water for four hours: then magnetised and kept two hours longer in steam. Its magnetic moment was then observed, after which it was laid on a wooden log, and violently beaten 50 times, both lengthways and sideways, with another mass of wood. It then showed a diminution of only $\frac{1}{500}$; and after a repetition of the beating only showed a loss of about $\frac{1}{400}$. In another experiment a tubular steel magnet was made glass-hard, magnetised, then heated for 30 hours in steam, re-magnetised and heated for 10 hours more in steam. This magnet when allowed to fall 10 times, on its ends, from a height of 1·5 meters, showed a permanent diminution of only $\frac{1}{4756}$ of its magnetism. It is accordingly recommended that all magnets for use in magnetic observations should be prepared as follows:—*Make the magnets glass-hard: then place in steam at 100° for 20 or 30 hours, or longer for very massive magnets. Then magnetise as fully as possible and then heat again for five (or more) hours in steam.* Such magnets will then be as constant as they can be made.

In quite another way Mr. G. Hookham† has sought to obtain magnets of constant power, for use in his electrical meters. A number of bar-magnets of tungsten steel are fitted into cast iron pole-pieces which nearly meet, so constituting a nearly-closed circuit. After these are fitted on, a magnetising current is sent round the bar-magnets to saturate them as fully as can be done. They are then mechanically hammered, and a weak de-magnetising current is sent through the coils, reducing the magnetism by about 10 per cent. Then for many months the magnet will show no tendency whatever to lose; indeed, it may slightly gain.

THE FRENCH MEDITERRANEAN CABLES.

The following is a translation from *Le Petit Marseillais* of July 13th. Cable-laying is, in these days, such a matter of routine that the difficulties it presented less than half a century ago may be worth recalling:—

The Chamber is about to vote a grant for the two new telegraph cables between Marseilles and the African coast—one from Marseilles to Oran and the other from Marseilles to Tunis. These new lines will increase to seven the number of the submarine wires which connect the metropolis with our great trans-Mediterranean colony, all of which land at Marseilles.

The first attempt took place in 1854. We had not the boldness then to undertake long distance lines, and it was therefore resolved to carry the line *via* Corsica and Sardinia, so as to have to submerge but relatively short lengths of cable—that is to say, Spezia-Corsica, Corsica-Sardinia, and Sardinia-Bona. The two first sections of the cable were laid without difficulty. The protective sheathing consisted of six iron wires ·008m. = in diameter. The weight of the cable was 5 kilogrammes per metre, an enormous weight necessitated by the heavy iron sheathing. It was next attempted to submerge the third portion between Cagliari and Bona, a distance of 200 kilometres; so that the weight of the cable was nearly 12,000 tons. The depth of the sea at one part of the track is from 2,800 to 3,200 metres. On arriving at the middle of the course where the greatest depths exist, the cable, dragged by its own weight, ran out with extreme rapidity, the breaks being powerless to hold it, and broke.

The second attempt was not more successful; the cable being paid out more rapidly than had been expected it was found too short, and it became necessary to stop laying when over a depth of 400 fathoms, and the ship did not possess buoys to enable the cable to be recovered and relaid. This was so much cable thrown into the sea as a pure loss. The two first sections of the cable worked on and off until 1863.

In 1857 the work of laying the third section was undertaken for the third time. On this occasion the dimensions were reduced, and consequently the weight of the cable, which had four conductors, was less. Each of these conductors consisted of four fine copper wires, and formed a spiral, covered with two layers of gutta-percha. These cores were placed together, and surrounded with a covering of hemp forming a bed for the 18 iron wires ·003m. = in diameter. For the shore ends the 18 iron wires were replaced by 12 galvanised wires ·005m. = in diameter. The cable was submerged between Cape du Garde, near Bona, and Cape Teulada, Sardinia. The work, commenced on September 7, 1857, at 8 p.m., owing to the calm weather, was finished next day at 10 p.m. When the ship was still 20 kilometres from the coast of Sardinia, the failure which characterised the second expedition was almost reproduced; the cable was too short, and it was necessary to join on a length of lighter cable, which was replaced a month afterwards by one of the same type as that of the rest of the line. During the laying it was necessary to stop two or three times to repair broken external wires. The cable running out with a speed much greater than that of the ship, the length submerged exceeded by about 40 per cent. the distance run by the vessel. This determined the engineers to change the route, and the cable was landed at Cape Teulada, in place of Cape Spartiventa as had been decided. The cable worked for about two years. The second cable was laid in 1861. It was composed of two sections, one from Port Vendres to Mahon, 418 kilometres, and the other from Mahon to Algiers, 426 kilometres. It only lasted one year.

The third cable was laid in 1864. On this occasion it was believed that every precaution had been taken, and none doubted a successful result. A foreign manufacturer had been chosen, and the cable had been constructed on a new model, which would not, it was said, give rise to any mishap. The cable was to be laid between Carthagena and Oran, and had been ordered from Messrs. Siemens, the manufacture being specially inspected by an engineer of the French Administration. A ship, the "Tenth December," had been bought expressly for the purpose of laying, and the then Director-General of French Telegraphs wished to preside himself at the installation of the new submarine line. The cable was composed of a copper conductor, surrounded by three layers of gutta-percha. Upon the gutta-percha were laid in opposite directions two layers of hemp, covered with a copper band, so laid on that one turn covered half of the previous turn. The total length was 300 kilometres, and the weight 200 kilogrammes per kilometre. The laying took place without serious accident, but the line only worked for a few hours, the cable breaking a few kilometres from the Spanish coast. Not discouraged, in 1865 the fourth cable was laid between Marsala, Italy, Biserta, and Tunis. It worked just two years. The fifth was laid between Bona and Marseilles by an English company in August, 1870; it is still working, as are also the four others which were subsequently laid in 1871, 1879, and 1880.

For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements should be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL PREPAID ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1891 Edition, published on the 23rd February, 1891, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with well-written Biographical Notices of leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1891 should be ordered at once. Price 5s., post free 5s. 9d. Abroad postage extra. Prospectuses free.

ELECTRICAL BOOKS AND PUBLICATIONS

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. Vol. I. Price 7s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Vol. I. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

Several Further Volumes in Active Preparation.

NOW READY, IN TWO VOLUMES.

POLYTECHNICS AND TECHNICAL INSTITUTES.

The demand for technical education is being actively met in London by the establishment of carefully devised polytechnics and technical institutes. We use the term "demand" in its economic, rather than its literal sense, for one of the chief difficulties in dealing with this important matter is that the persons for whom these institutions are founded are unable, if only on account of their youth, to define or even to express their needs. A praiseworthy attempt was made by the establishment of the Science and Art Department to supply something of the kind, but, instead of making an endeavour to find out what was wanted, the promoters assumed that nothing could be better than the best, and so overshot the mark, and have failed to reach those classes whose requirements are now being studied and provided for. The Science and Art Department, in spite of its mischievous system of payment by results, has done very good work, as is shown by the report which was presented to Parliament a few days ago, and for the sake of this work, and of its value to the country, we are reluctant to criticise it; but, knowing how much an eager learner will make of the smallest facilities for scientific study, we are inclined to attribute a large share of the success to the students themselves, who have risen above the cramming and the examination papers, and have acquired a large amount of useful and thorough science.

Digitized by Google

The City and Guilds of London Institute are doing work of immense value, and they not only reach the artisan classes and the apprentices, but carefully lay out a programme having some regard for their actual requirements. But they cannot help doing higher work at the same time, and there is a strong temptation to develop this at the expense of the strictly technical teaching. A difficulty of a similar character has been met with in the building of industrial dwellings. Philanthropists, shocked at the dirt, squalor, and overcrowding in the slums, raised large blocks which they imagined to be excellently suited for the poorest classes, who, it was thought, would speedily flock to them. But the so called sub-professional class were more ready to occupy them, and the dwellers in the slums were found not only to be unwilling to change their mode of life, but to be unconscious of some of its worst evils. No one grudged the use of this accommodation by clerks and governesses, but until closer attention and further experience showed how these buildings should be constructed, the misery which originally excited the philanthropy was not touched.

A priori reasoning is as likely to miss the mark in the matter of technical education, as it is in physical science. If the premises be true, and the reasoning be accurate, some real result will be reached; but it may not be the one desired. The method of experiment, nearly always the more costly, is undoubtedly more sure. Such experiments have been made, and a study of their results is very interesting. A most important example is to be found at the Polytechnic in Regent-street, which, begun in 1873, was transferred to its present quarters in 1882. In that year Mr. BESANT'S "All Sorts and Conditions of Men" was published, and everyone knows how the ideal People's Palace was soon realised with most of its pleasant details in the Mile End-road. For various reasons, it was soon found that the leading principle of recreation was apparently impracticable, and was probably before its time. A large investment was made in bricks and mortar, and such an investment, instead of yielding interest, entails a considerable cost for up-keep. Endowment was either forgotten or it was imagined that the scheme would pay its own way. When serious difficulties arose, the Drapers' Company and the Charity Commissioners came to the rescue, and it was recognised that, while the East Londoner's "capacity for innocent enjoyment" had not been clearly estimated, there was no doubt that the work-a-day departments in which book-keeping and shorthand were taught, were not only thoroughly appreciated, but were nearly, if not altogether, self-supporting. This result is instructive, and the details of the experience which such important experiments provide have not been lost sight of in the movement for establishing polytechnics and technical institutes in the more crowded parts of London. It is clearly recognised, in the first place, that, as with the highest branches of learning, education cannot be self-supporting, but must receive external assistance. The scope of the work has in several cases, and we hope will in others, be strictly limited to the classes for whom it is intended. Thus, we understand that at the People's Palace a condition for receiving a lad for training as a mechanic is that his parents do not earn more than £200 a year. Many persons will object to such a limitation, but the case is very similar to that of a hospital, which is not intended for, and is justified in rejecting, those who are able to command the services o a doctor. But such limitations are, to a certain extent, artificial, and the true way to reach and to retain the young artisan is to discover, by most careful observation, his exact requirements and those of the class to which he belongs. A scholarship by which, as by a stepping-stone, some exceptionally brilliant student may be passed on to a higher institution, will not necessarily tempt either the teacher or his class to aim too high, and need not in any way introduce the very inexpedient system of payment by results.

Having set on foot a course, or a number of courses, of technical study and training, whether for boys and girls between their schooling and their trade, or for apprentices after their work, recreation naturally follows, and a systematic and well-organised department is to be found in connection with all the polytechnics, though assuming different orders of importance in various localities.

If the complicated difficulties of piece-work could be overcome, and each artisan, after a good training at a technical institution, could, as *The Times* of Monday says, come to love excellence for its own sake, and be proud of his power of producing it, there would be but little difficulty about long hours, and there would, if he desired it, be plenty of time for recreation. By the better training which is now being provided, the quality of the work done should constantly improve, and the revival of the element of personal pride of the worker in his own handiwork may reasonably be looked for; a pride which is stamped on the best workmanship of to-day, but which was far more prevalent and characteristic before the days of trades unions. A more noble ideal than is taught in Hyde Park would be a trades union in which every member must have passed through a technical institute, and must after he has served his time, show, and afterwards maintain, a certain proficiency in his craft.

THE HISTORICAL DEVELOPMENT OF THE INDUCTION COIL AND TRANSFORMER.

BY DR. J. A. FLEMING, M.A.

(Continued from page 302.)

§ 15. **Foucault's Experiments with Two Coils.**—In the *Comtes Rendus* for 1856 (Vol. XLII., p. 215), Foucault describes an interesting experiment which he made with two Ruhmkorff induction coils. He desired to obtain long sparks by adding together the potential of two induction coils. With this object he joined the primary circuits of two similar coils in parallel, and operated them by the current from one and the same battery. Under these circumstances the contact breakers did not vibrate in step, and the secondary spark length, resulting from joining the two secondary circuits in series in the proper way, was not the sum of the lengths of the separate secondary sparks. He discovered an ingenious way of making the contact breakers keep in step. This was effected by joining a piece of wire across from the end of one primary coil to the similar end of the other, this junction being effected between the contact breaker and the beginning of the primary coil. When this was done each hammer kept the other in step with itself, and, on joining up the secondary circuits in series in the proper manner, he obtained a secondary spark double in length (viz., 18 or 20 mm.) of that of each coil separately.

§ 16. **Stöhrer's Induction Coil.**—In 1854 Emil Stöhrer directed his attention to the improvement of the induction coil,* and produced a form of coil which is represented in Fig. 23. The instrument consisted of a primary wire and core of divided soft iron arranged in a vertical position, the iron wires being of 1mm. diameter, and standing loosely in a cylinder of wood so that they could be removed one by one if desired. The iron wires were varnished with shellac. The primary coil consisted of six layers of double covered wire 1mm. in diameter, the height of the whole spiral being 20 centimetres, and its diameter over all 50mm. The secondary coil consisted of three independent coils wound

* See *Poggendorff's Annalen*, May, 1856; also *Phil. Mag.*, 1857, Vol. XIII., 4th series, p. 55.

Digitized by Google

on separate bobbins made of varnished paper with cheeks of pear-tree wood. The wire was insulated with silk and well varnished, and insulated with a mixture of wax and resin. Stöhrer employed an independent electro-magnetic contact breaker, and a condenser of which the dielectric consisted of waxed cloth. He obtained good secondary sparks 12 or 14 "lines" in length. He tried producing, as Sinsteden had suggested, an arc light between coke points by means of the secondary discharges, but he was not aware of the previous results of Callan or of Page in this respect, and his coil evidently furnished too small a "quantity" of current to enable him to obtain an arc.

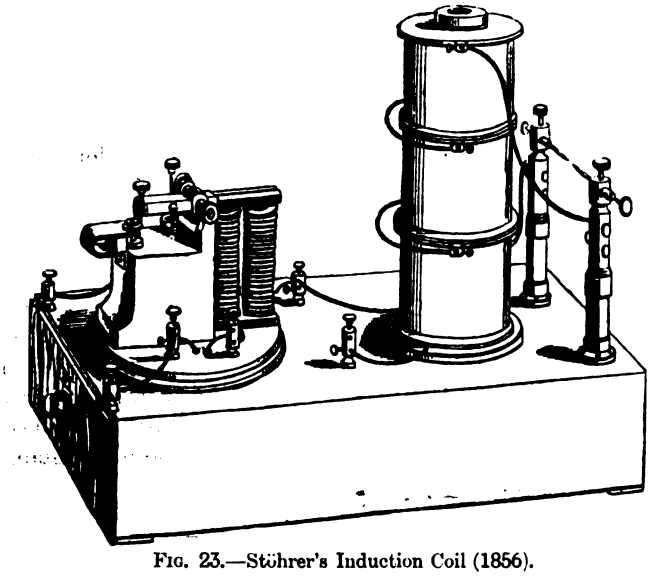

FIG. 23.—Stöhrer's Induction Coil (1856).

§ 17. **J. N. Hearder's Induction Coils.**—Mr. J. N. Hearder, of Plymouth, began, in December, 1855, the construction of induction coils, and his Papers describing his work are to be found in the *Philosophical Magazine* for November and December, 1856 (4th series, Vol. XII., p. 377).* Hearder had his attention drawn to the subject by the Paper of Grove in 1855, to which reference has been made already, on the employment of a Leyden jar in connection with the secondary circuit, and this Paper stimulated him to examine the construction of Ruhmkorff's induction coil. After many experiments he was successful in producing a coil for which he obtained a silver medal from the Royal Cornwall Polytechnic. It appears that up to the time of Hearder's experiments he (Hearder) had not, apparently, seen any one of Ruhmkorff's induction coils capable of giving a greater length of secondary spark than three-quarters of an inch. Hearder adopted sheet gutta-percha as his insulating material for the secondary coil, and he describes the chief differences between his own and Ruhmkorff's coil as follows:—He says (*Phil. Mag.*, Vol. XIV., 4th series, 1857) that Ruhmkorff's secondary wire was insulated with cotton, whilst he used silk-covered wire. Ruhmkorff employed shellaced paper between the layers of the secondary coil, whilst he used sheet gutta-percha or thin vulcanised sheet india-rubber. He also claims that he improved the iron core by using smaller iron wires than Ruhmkorff, and that, in place of oiled silk for the condenser dielectric, he substituted vulcanised india-rubber, gutta-percha, or varnished cartridge paper. He also states that he improved the contact breaker by using a stiffer spring, the rate of vibration of which he could alter, within certain limits, at pleasure, by means of a screw.

Hearder noted particularly the limitation imposed by the tendency to discharge from layer to layer of the secondary coil over the ends of the layers of insulator, and he prevented this by extending the sheet gutta-percha placed between the several layers of wire a good way beyond the wire windings, so that the discharge would have to take a longer path through air to get round. A considerable controversy sprang up between Mr. J. N. Hearder and another improver of the induction coil, Mr. C. A. Bentley, as to who was the first to suggest these modifications, and was continued with some bitterness between them (see *Phil. Mag.*, Vol. XIII., 1856, p. 325). Bentley's description of his coil is to be found in the *Philosophical Magazine* for 1856 (Vol. XII., 4th series, p. 319). He constructed a coil capable of giving secondary sparks two inches long in air when the primary current was produced by four or five Grove's cells. Bentley also adopted sheet gutta-percha for the insulation of the various layers of the secondary coil, but whether before or after Hearder it is difficult to say. He employed an electro-magnetic break having a very stiff spring to the hammer, the time of vibration of which he could vary at pleasure. He used also a condenser made of tinfoil and varnished paper.

Hearder constructed about this time a coil some 12 inches in length, in which the secondary circuit had a length of three miles, and from which he obtained secondary sparks about three inches in length. He noted that if the discharge was taken between fine platinum terminals not more than 0·5 inch apart, the negative terminal became white hot very soon, and began to melt. He made many experiments on discharges in air and in vacuo between terminals of different forms.*

Hearder published a Paper in the *Philosophical Magazine* for 1857 (Vol. XIII., p. 325), in which he makes many observations on the heating power of the secondary discharge, both when the terminals were connected to a Leyden jar in the manner described by Grove, and when they were not. He found that whereas the simple secondary current could not, under certain circumstances, heat a few inches of platinum wire red hot, the mere interposition of a Leyden jar across the secondary terminals caused the platinum wire to be heated to redness, or to be fused, thus showing an increase in the quantity of each discharge.

Bentley asserted that he had independently adopted these same improvements as Hearder, and that, by following this mode of construction, Mr. Ladd had obtained sparks 4½ inches long. The points at issue between these inventors are not very important except as showing that several minds had addressed themselves to improving Ruhmkorff's coil, and that the causes limiting the sparking distance were gradually being generally understood.

§ 18. **Ritchie's Induction Coils.**—Mr. E. S. Ritchie, of Boston, U.S.A., began apparently to study the construction of the induction coil in or about 1857, and, probably, not knowing what had been done by Poggendorff, he again brought forward the suggestion of insulating the secondary coil vertically instead of horizontally. A Paper by Ritchie is to be found in *Silliman's American Journal of Science* for November, 1857 (Vol. XXIV., p. 45). In this Paper, Ritchie enumerates the causes of the difficulties met with by Stöhrer and Hearder in lengthening the secondary spark beyond three inches, and proceeds to describe his own improvements. Ritchie wound the secondary wire on a glass tube, beginning near one end and winding the wire in a sort of very steep cone (*see* Fig. 24). When this cone of wire was wound on, a *washer* or disc of vulcanised rubber was slipped on and cemented with beeswax and resin, and the end of the wire passed down and insulated with a strip of rubber, and then another cone of wire built up until the whole tube was wound full of coils, insulated from each other with washers or discs of sheet rubber. With a helix so made of 7,000ft. of wire Ritchie obtained a secondary spark of 2¼ inches, and with 30,000ft. of wire a spark of six inches. He supplied the above coils with condensers, having respectively 30 and 75ft. of coated surface, the insulator being thin sheet gutta-percha. He found that it was very important to get high insulation between the primary and the secondary coils, and that it was necessary to overlay the glass tube on which the secondary was wound with many sheets of gutta-percha tissue. In 1859 Ritchie sent to Franee, by MacCulock, a coil made in the above way, which gave secondary sparks 35 centimetres in length, which astonished the French savants, they, as Du Moncel says, not knowing nor caring to know the results of the previous work of M. Jean. A recent coil, made about 1860 by Ritchie, is figured by Du Moncel in

* It is stated in Noad's *Manual of Electricity*, Part II., that Hearder began his work on induction coils in 1846, but this is incorrect.

* See *Phil. Mag.*, Vol. XII., 4th series, 1856, pp. 377 and 443.

Digitized by Google

his book on the Induction Apparatus of Ruhmkorff, and is shown in Fig. 25. The coil was 120 centimetres in length, and contained 52 kilograms of wire, and weighed in all 112 kilograms. The bobbin was composed of two separable portions, and, in fact, was two distinct coils. The core was a bundle of iron wires each one millimetre in diameter. The primary coil was 60 metres long, and constructed of wire five millimetres in diameter. The secondary coil was 71,200 metres, or nearly 45 miles in length, and constructed of wire ·18 millimetre in diameter. It was made of the purest copper, covered with silk, and wound in a series of flat helices of one thickness of wire, the different spirals being insulated with paraffined paper.

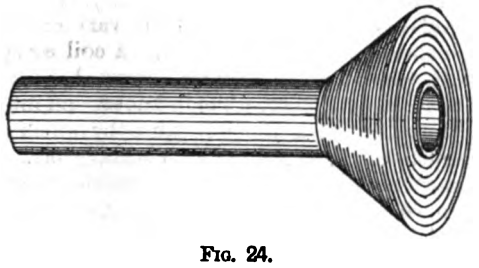

Fig. 24.

The insulation between the primary and secondary coils was separated by a glass tube, and layers of vulcanised caoutchouc placed over it. The condenser consisted of sheets of tinfoil of 30 square decimetres in area, insulated with oiled silk, and arranged so that more or less of the surface could be utilised. The interruptor was a hammer-break, actuated by an electromagnet separate from the coil. The length of each section of the bobbin was 33 centimetres, and the external diameter of the coil 22·8 centimetres. With the currents from three large bichromate cells the secondary sparks were 53 centimetres in length.

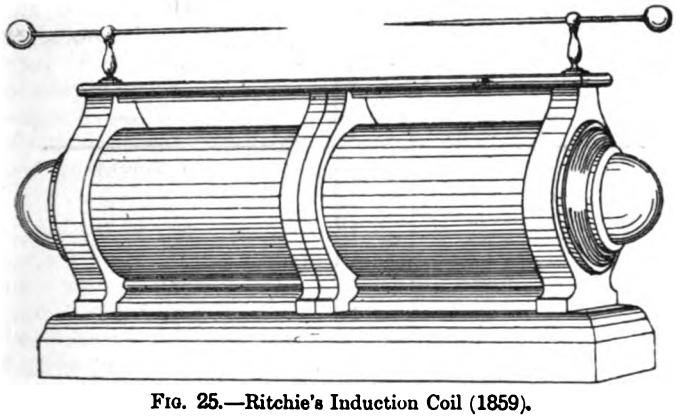

Fig. 25.—Ritchie's Induction Coil (1859).

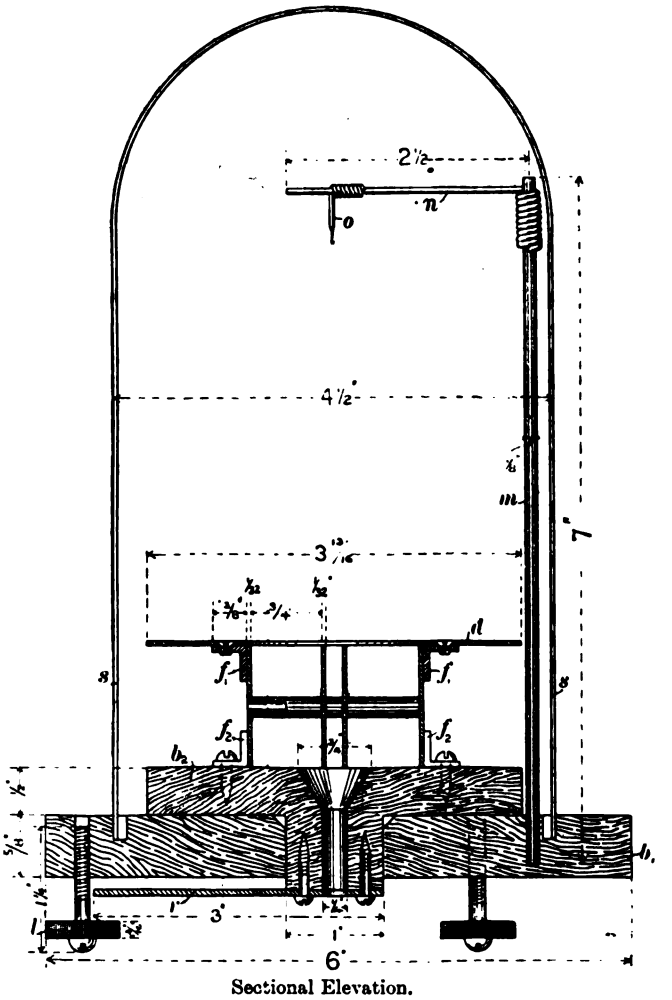
§ 19. Mr. Gassiott's Large Induction Coil.—In 1858, Ritchie constructed, to the order of Mr. John P. Gassiott, a large induction coil, which is thus described by Mr. Gassiott in the *Philosophical Magazine* for 1858 (Vol. XV., 4th series, p. 466): "The primary coil is of wire of No. 9 gauge, the helix in three layers and 15in. in length, taking altogether 150ft. of wire. The iron core is 18in. in length and about 1¾in. in diameter, of annealed iron wires, No. 16 gauge, annealed with the very greatest care, having been a fortnight in cooling. The primary wire has a cover of gutta-percha, one-tenth of an inch in thickness; over this a glass tube. The secondary helix is divided into three bundles, each five inches in length, wound on cylinders of gutta-percha, the total length of secondary wire being 73,650ft., or 14 miles." The secondary wire was insulated and wound vertically, that is, in separate flat helices. The condenser consisted of varnished tissue paper, three layers of each sheet between every sheet of tinfoil, and there were three condensers which could be employed, of 50, 100, and 150 square feet of coated surface respectively. The coil would give 12½in. sparks. The interruptor was a ratchet break worked by hand, which enabled various rates of interruption to be applied. This coil was used by Mr. Gassiott in his researches on electrical discharge in vacuo, and gave very fine effects.

(To be continued.)

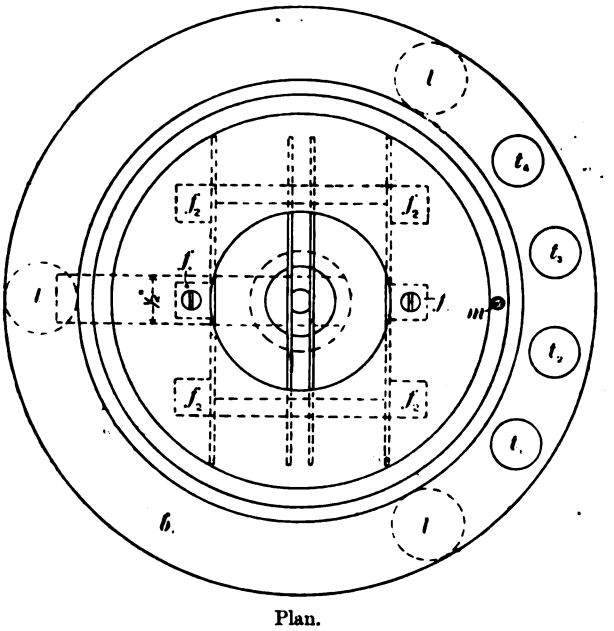
ELECTRICAL INSTRUMENT MAKING.—III.

SUSPENDED NEEDLE GALVANOMETER.

The galvanometer to be described in the present article will be of use in many cases where the extreme delicacy of a reflecting galvanometer is not required, but a mirror may be employed with this instrument in some cases, such as balance tests with a zero method.



Sectional Elevation.



Plan.

Fig. 1.

The base of this instrument is in two parts; the lower part, *b*, is 6in. in diameter and ⅝in. thick; there is a hole through

Digitized by Google

its centre 1in. in diameter; around this is a concentric groove, into which the glass shade, *s*, of the instrument fits. This groove must be capable of taking a shade 4½in. in external diameter, but should be made wide (⅛in.), so that a smaller shade may be used in case this size is not to be readily procured. If the shade is a loose fit, a few little pieces of wash-leather should be fixed round its edge. The groove should be about ¼in. deep. On the underside of the base b_1 are three levelling screws, *l*, l_1, *l*. These consist simply of 1¼ No. 12 brass screws, with flanges $\frac{3}{16}$in. thick and 1in. to 1¼in. diameter, soldered to them close up to the heads; the rims of these flanges should be milled. The slots in the screwheads should be filled up with solder, and the screwheads smoothed up with fine emery paper. The coils of the instrument are carried on a revolving base b_2; this is shown 3$\frac{3}{16}$in. diameter and ½in. thick. On its underside is a central projection, 1in. in diameter and ⅜in. deep, which passes through the central hole in b_1; great care must be taken in making these fit well; b_2 should be able to turn sweetly and easily in b_1, but at the same time there should be no side-play, the rubbing surfaces of both b_1 and b_2 should be made quite smooth with

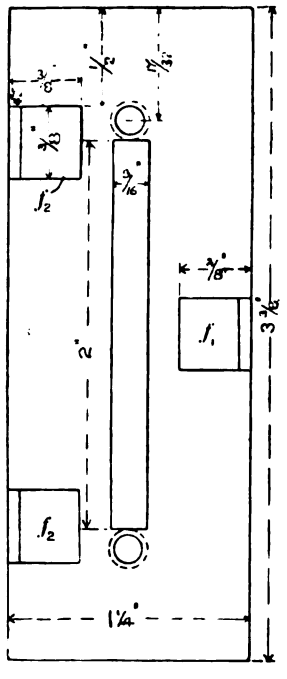


Fig. 2.

fine glass-paper, and before the instrument is finally put together, they should be rubbed with plumbago, and *not* varnished. The exposed surface of the wood should, of course, be varnished or French polished, not so much for the sake of appearance as for enabling it to be kept clean. Through the centre of b_2 is a funnel-shaped hole, through which the connections pass to the terminals *t*; screwed on to the bottom of the projecting centre of b_2 is a strip of brass, *r*, 3in. long, ½in. wide, and about $\frac{1}{16}$in. thick, by means of which the revolving base may be turned round without removing the shade. The bobbins for the coils of this instrument (Fig. 2) are constructed in the same manner as of the galvanometer last described. Their dimensions, however, are different, the length being 3⅜in.; height, 1¼in; width of coils inside cheeks, ¾in.; space between inner cheeks, $\frac{3}{16}$in.; width of slots, $\frac{3}{16}$in.; length of slots, 2in.; distance from centre of rivetting wire to end of cheek, $\frac{19}{32}$in. There are six lugs, similar to those described in the preceding article; the two top ones, f_1, hold the dial d_1, while the coils are fixed to b_2 by means of the four lower lugs f_2, the holding being effected by means of ½in. No. 6 round-headed screws. The dial of this instrument is also similar to that of the pivoted galvanometer (*The Electrician*, June 26th), its outer diameter being 3$\frac{13}{16}$in., and that of the central opening 1$\frac{13}{16}$in. The four ends of the coils should be soldered to four pieces of flexible wire cord, which should pass through the central hole in b_2. The joints, after having been carefully insulated, should be pulled into the wide part of the hole, and the flexible cords, where they come out from the opposite end of the hole, should be firmly wedged in position (so that they cannot possibly twist when b_2 is turned round). Their other ends are connected to the terminals. The ends of one coil should be connected to terminals t_1 and t_3, and the ends of the other to terminals t_2 and t_4, so that when terminals t_2 and t_3 are joined across, the two coils will act together in series, and when t_1 t_2 and t_3 t_4 are joined across respectively the coils will be acting together in parallel.

The gibbet for the suspension of the needle system may be constructed in the following homely fashion:—A piece of No. 9 S.W.G. brass wire, *m*, is straightened and fixed vertically in b_1. A piece of No. 16 S.W.G. brass wire *n*, 2½in. of which is made quite straight, is coiled into a spiral of eight or ten convolutions, which slides fairly tight upon *m*. A similar spiral, *o*, of No. 18 S.W.G. wire which slides tight upon *n* is about ⅜in. long, and is filed to a long fine point, which is bent round into the form of a hook; into this hook the silk fibre by which the needle system is suspended; is cemented with sealing-wax. It will be seen at a glance that this arrangement enables the position of the needle to be adjusted in any direction, vertically or horizontally.

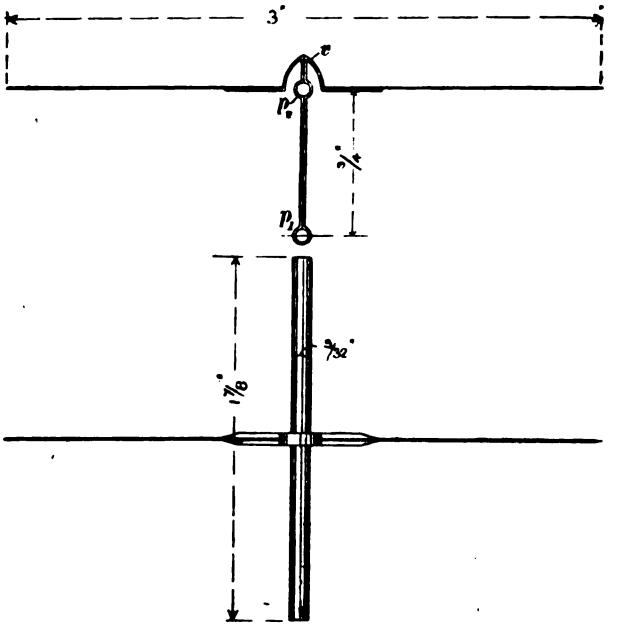

Fig. 3.

The needle system has two needles of round steel, $\frac{3}{32}$in. in diameter by 1$\frac{7}{8}$in. long; these are suspended in a stirrup made as shown in Fig. 3. A piece of very thin brass or copper strip, 3in. long and ⅛in. wide, is doubled to form a circular loop, p_1; this is to hold the lower needle. The two sides are then whipped together with silk for a distance of about ⅝in., when they again separate and form a loop, p^2, through which the upper needle is to pass. The centres of the two loops should be ¾in. apart. The two ends of the strip are whipped together again for about $\frac{3}{16}$in., when they separate, being bent downwards and outwards on opposite sides of the needle, as shown in Fig. 3. To the wings thus formed pointers of glass should be fixed with sealing-wax. Glass tube may be drawn down very fine by heating it to redness over a spirit lamp, and pulling the ends sharply apart. With a little practice, very fine and straight pointers may be made in this way. The ends of the pointers should be dipped into ink, which will flow up into them owing to capillary action. The pointers must be, of course, set exactly at right angles to the needles, a bit of fine brass or copper wire is passed under the wings at *r*, and is twisted into a hook; to this the silk fibre is fixed with sealing-wax.

To suspend the needle system, place two drops of sealing-wax on a piece of white paper about 8in. apart. Then persuade one end of a piece of single silk cocoon fibre to rest on one of the drops of wax, and as soon as it does so touch it with a hot wire to make the sealing-wax stick to it. The fibre should then be

Digitized by Google

stretched over the other drop of sealing-wax and stuck to it in the same manner. The silk should be a little slack when the paper is flat. The hook *o*, having been previously armed with a minute drop of sealing-wax, is hooked on to the silk fibre in such a manner that the fibre passes round it twice; it is then touched with the hot wire so as to fix the fibre. The hook of the needle system is fixed in the same manner, at a point about 4in. from *o*. The outer ends of the fibre are then cut away close to the hooks, and the whole hung up by the needle system, so that hook *o* is capable of turning freely. It should be left in this position for a day or so, in order that the twist may be taken out of the fibre. The needle system may then be placed within the coils of the galvanometer, and the spiral *o* slipped on to *n*, which has previously been lowered. The arm *n* should only be raised when the instrument is in use.

THE FRANKFORT EXHIBITION.—V.

(FROM OUR SPECIAL CORRESPONDENT.)

In the hall allotted to scientific and surgical apparatus Siemens and Halske occupy a large space, and have set up a laboratory where the instruments are shown in use. Here are to be seen all the well-known measuring instruments for which the firm is renowned. Amongst the exhibits attention may be called to a modification of Thomson's double bridge, enabling one to measure resistances from a tenth of an ohm to a microhm. The laboratory apparatus includes a selenium-photometer, and an electric pyrometer, for measuring temperatures up to 800°C.

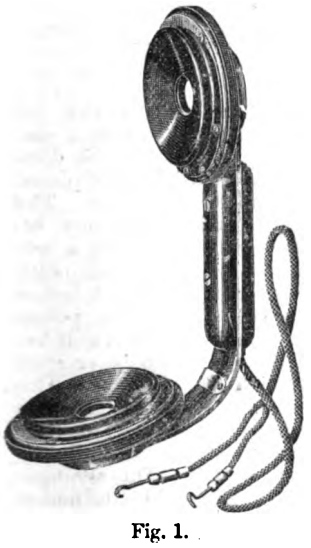

Fig. 1.

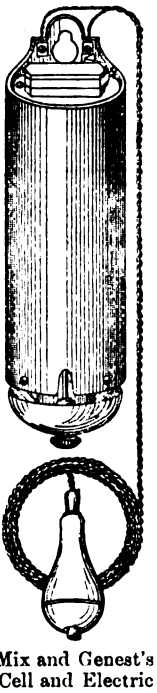

FIG. 3.—Mix and Genest's combined Dry Cell and Electric Bell.

In the Telegraph and Telephone Hall the firm of Mix and Genest, of Berlin, have an interesting collection. The most prominent object is their multiple switchboard for 6,000 subscribers. A practical idea which has been well carried out by this firm is their portable telephone, consisting of a spoon-shaped telephone and a microphone in one instrument, united by a handle (Fig. 1). The apparatus is provided with an ornamental stand for office and indoor work, and an oak case for work in the field, &c. (Fig. 2). The instrument is well adapted for military purposes. The case comprises a microtelephone with lever for closing the microphone battery, the induction coil of the microphone in connection with a "Neef" hammer serving to produce alternating currents of sufficient strength to call up the telephone at the far end, and two small dry cells. Another compact device exhibited by Messrs. Mix and Genest is a combined dry cell (Klingel) and electric bell (Fig. 3).

Work on the line for the electric transmission of power from Lauffen, on the Neckar, to Frankfort is in full swing, and a number of workmen are busy, under the instructions of the German Post Office and the Wurtemburg telegraph officials, in erecting the posts, fixing the insulators, and running the wire. This work, as well as that of installing the machines, will be completed by the middle of August. The Imperial Chancellor

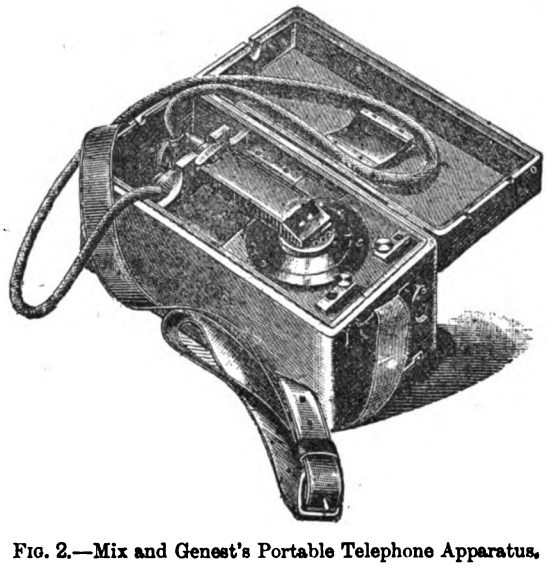

FIG. 2.—Mix and Genest's Portable Telephone Apparatus.

has appointed Prof. von Helmholtz, President of the Committee, to watch and report on this undertaking, which Committee consists of Drs. Löwenherz, Lummer, and Brodhun. Profs. Dietrich (Stuttgart) and Weber (Zurich) are also to report on the work for their respective Governments.

THE ELECTRIC TRANSMISSION OF POWER.*

BY GISBERT KAPP.

LECTURE II.—*Fundamental Principles.*

(Continued from page 310.)

The fundamental principle on which the electric transmission of power depends is that peculiar, and, I might almost say, mysterious interaction between magnets and currents, which we comprise under the name electro-magnetic induction; but more particularly two special cases of electro-magnetic induction, the one discovered by Oersted and the other by Faraday. Oersted discovered that, under certain conditions, a compass needle is deflected by an electric current, and Faraday discovered that relative motion between a magnet and a magnet and a closed conductor will, under certain conditions, produce a current of short duration in the conductor. Oersted's effect is a permanent one; the needle remains deflected as long as the current flows. Faraday's effect is transient; the current flows, not as long as the magnet is present, but only during the time that it takes to change the relative position of magnet and closed conductor.

It is clear that in Oersted's experiment the movement of the needle is due to the action of a mechanical force between the magnet and the coil. In Faraday's experiment the transient current must be caused by a transient electromotive force, and this, in its turn, is caused by the relative movement between the coil and magnet. The modern method of explaining these things is based on the conception of magnetic lines of force, and the looping of these lines with the wire coil through which the current flows. The whole subject has been so admirably laid before this Society in the Cantor Lectures on the Dynamo, which Prof. S. P. Thompson delivered here in 1882, that I need not occupy time by going over the same ground again, but may take it for granted that you are familiar with the lines of force theory. In modern language, we

* Cantor Lectures delivered before the Society of Arts, February, 1891

Digitized by Google

may therefore explain the two fundamental phenomena somewhat as follows :—

1. The looping of a current with magnetic lines of force sets up a mechanical force between the conductor and magnet (or its equivalent).

2. Relative movement between a magnet (or its equivalent) and a wire coil sets up in the latter an electromotive force.

It follows immediately from these two propositions that looping and movement combined will require the expenditure of power, or yield power, accordingly as the movement is opposed to, or in the direction of, the mechanical force produced by the looping. In other words, that we can, by these simple means, convert mechanical into electrical power, or electrical into mechanical power. If we carry out both processes at the same time, that is, if we combine Faraday's with Oersted's experiment, we require, of course, a pair of wires between the two converting instruments. In Faraday's experiment, if we thrust the steel magnet into the wire coil, we expend mechanical power, which is converted into the electrical power represented by a current flowing under a certain, though in this case very small, potential difference. The power represented by

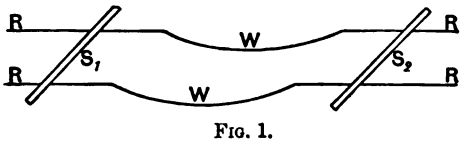

FIG. 1.

this current is again reconverted in Oersted's experiment into mechanical power, which is used to produce the deflection of the magnet. The total amount of power thus transmitted from one place to another is, of course, exceedingly small, but the same principle, applied on a larger scale, effects the transmission of many horse-powers, and it will be my task to show you how this is done in practice.

Before entering upon this subject, I must explain an expression used in stating the fundamental principles on which the electric transmission of power is based. I said that we require a coil and a magnet "or its equivalent." The equivalent of a magnet is, as you know, a coil through which a current flows, and the experiments ought, therefore, also to succeed if instead of the magnet we use such a coil. In practical work we use neither a steel magnet nor a coil alone, but a combination of a coil with an iron core, constituting what is known as an electro-magnet.

You know that, according to our modern conception of magnetic fields, there emanates from each pole of a magnet a certain flow of lines of force ; and when we thrust a magnet into a coil we cause the individual wires of the coil to cut through the lines of force. The quicker the movement, that is to say, the more lines of force are cut by each wire in unit time, the greater is the E.M.F. produced ; and the more wires are contained in the coil, the greater is the E.M.F. produced, since the E.M.F. impulses of the different

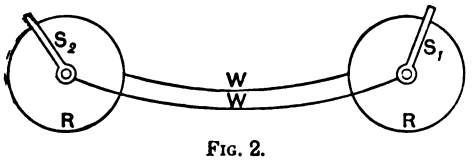

FIG. 2.

convolutions are added. It is also easily seen by experiment that the stronger the magnet the greater will be the E.M.F. ; so that we find that the E.M.F. is proportional to the product of strength of field, speed of cutting, and length of conductor. Denoting these quantities respectively by H, v, and l, the E.M.F. produced is in C.G.S. units $H\ v\ l$, and remembering that a hundred million C.G.S. units of E.M.F. are equivalent to one volt, we have the E.M.F. in volts given by the expression

$$\text{Volts} = H\ v\ l\ 10^{-8}.$$

In this formula the strength of field is given in lines per square centimetre, and speed and length are given in centimetres.

The mechanical force experienced by a conductor in the neighbourhood of a magnet pole is, according to our modern views, due to the fact that the conductor is laid across the lines of force emanating from the magnet pole. The force in dynes is given by the product, $H\ c\ l$, c being the current. Since there are 981,000 dynes required to represent the force of one kilogramme, and since the C.-G.-S. unit of current is 10 amperes, we have the force produced by a current of c amperes—

$$\text{Kilogrammes} = \frac{H\ c\ l}{9{,}810{,}000}.$$

These are the two fundamental equations required in the design of plant for the electric transmission of power. Now let us see what is the most simple kind of plant we could possibly employ. At the generating station we require a conductor cutting lines of force ; this conductor must be joined by wires with a similar conductor at the receiving station. The second conductor is also laid across lines of force, so that when a current passes it will be acted upon by a mechanical force displacing it parallel to itself and doing work. The arrangement here described is shown in Fig. 1, where the lines R represent fixed, horizontal, parallel rails, across which are laid sliding rails or sliders, S_1, S_2. Imagine the magnetic lines of force passing vertically between the fixed rails, then, if we displace the slider S_1, an electromotive force will be set up in it, causing a current to flow through the connecting wires, W, and the slider S_2 at the receiving station. The slider S_2 is supposed to be laid across lines of force, and will, therefore, be acted upon by a mechanical force. Thus, power may be electrically transmitted from the slider S_1 to the slider S_2. It will immediately occur to you that the experiment I have here illustrated could easily be tried by means of any railway. The fixed conductors and connecting wires would be the rails ; the generating slider would be a crowbar thrown across them, and hauled along by a train ; and the lines of force would be supplied by the vertical component of terrestrial magnetism. At another part of the railway— possibly miles away —another crowbar thrown across the rails should then be set in motion, by the current passing through it. Theoretically, such an arrangement represents correctly enough the electric transmission of power ; but I need hardly tell you that it would not work in practice. If you apply the E.M.F. formula I have given to this case, you will find that, even if the slider is hauled along at the speed of an express train, there will only be generated about the one-thousandth part of a volt, the reason being that the magnetic field provided for us by nature is so extremely weak. If we could apply an artificial magnetic field of the strength generally employed in dynamo machines—that is, about 10,000 times as strong as the vertical component of terrestrial magnetism—then we could get

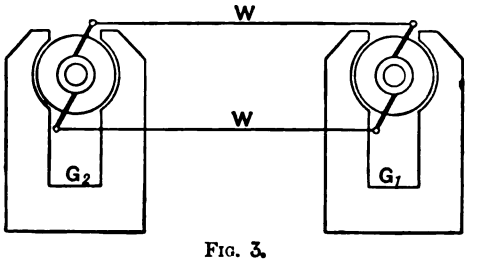

FIG. 3.

about 10 volts in our slider. Now, it is obvious that we cannot spread so strong a field over miles of railway ; and we must, therefore, alter our arrangement. This may be done as indicated in Fig. 2, where one of the rails has been replaced by a centre contact, and the other by a circular conductor. The slider, instead of being moved parallel to itself, must now revolve round the centre contact, which can easily be done by a belt and pulley. We have thus arrived at what is known as a non-polar dynamo. But even this arrangement, although very much better than the progressive slider, is not of practical value for power transmission, because the E.M.F. of non-polar dynamos is still too low. It is only a few volts, whereas we require hundreds, or even thousands, of volts to carry the current to any distance. The obvious remedy is to use a large number of revolving sliders, so connected that the E.M.F. generated in each shall be added ; in other words, instead of a non-polar dynamo, we must use an ordinary continuous current dynamo, wound for high E.M.F. This arrangement is shown in Fig. 3, where G_1 is the generator and G_2 the motor or receiving dynamo. If you connect their brushes, as shown in the diagram, and rotate the armature of the generator, a current flows through it, the line wires W, and through the armature of the motor, and exerts upon the latter a mechanical force, tending to produce rotation and give off mechanical power. I am able to show you this experimentally, by means of two dynamos connected, as shown in Fig. 3.

The Machines Employed in Power Transmission.

This experiment has shown how power may be transmitted electrically. Let us now consider somewhat more in detail the different parts of the transmitting plant. At one end of the line of transmission we have the generating dynamo, at the other we have the motor dynamo, and then we have the line itself, consisting of two wires insulated from each other and from earth. You will readily see that although for the convenience of experimental illustration I have placed the generator and motor close together, this proximity was not an essential condition of the experiment. The motor might have been placed in another room, or in a different part of London, and still the experiment would have succeeded, provided I had used sufficiently stout and well-insulated connecting wires. But then you could not have had

Digitized by Google

ocular demonstration of the fact that movement of the generator armature is closely followed by a corresponding movement of the motor armature.

A full treatment of my subject would, of course, include a complete investigation of the dynamo, but this I shall not attempt. In the first place there is no time for it, and in the second place it is hardly necessary, since you are all more or less acquainted with these machines. I shall, therefore, not occupy time by giving mathematical proofs for the few formulæ I shall have to use, but assume that they are familiar to you. They are as follows :—

$$\text{Volts} \ldots\ldots \ldots = H\,v\,l\,10^{-8}$$
$$\text{Kilogrammes} \ldots = H\,c\,l$$
$$\overline{9{,}810{,}000}$$

C Total current through armature ; c, current through single armature conductor.

e_a E.M.F. in armature in volts.

τ Number of active conductors counted all round armature.

p Number of pairs of poles ($p=1$ in a two-pole machine).

n Speed in revolutions per minute.

F Total induction in C.-G.-S. lines.

Z ,, ,, English lines.

Electromotive force

$$e_a = F\tau\frac{n}{60}10^{-8}$$
$$e_a = Z\tau n\,10^{-6}$$

for two-pole machines.

$$e_a = pF\tau\frac{n}{60}10^{-1}$$
$$e_a = pZ\tau n\,10^{-6}$$

for multipolar machines with series-wound armature.

Torque.....

Kilogramme-metres $= 1{\cdot}615\,F\tau C\,10^{-10}$
Foot-pounds $= 7{\cdot}05\,Z\tau C\,10^{-6}$

for two-pole machines.

Kilogramme-metres $= 3{\cdot}23\,F\tau cp10^{-10}$
Foot-pounds $= 14{\cdot}10\,Z\tau cp10^{-6}$

for multipolar machines.

In analysing these formulæ you will observe a curious parallelism. The symbols for field strength and total number of active armature wires occur in either group, but the current occurs only in the group giving torque, or mechanical turning effort, and the speed occurs only in the group giving E.M.F. Now, if you multiply any of the torque formulæ with the speed you get on the left—mechanical power ; and on the right the product of electromotive force, multiplied with current and a constant, or, in other words, electrical power ; by working this out in figures, you will find that mechanical energy expressed in horse-power is equal to watts divided by 746, the well-known equation for converting mechanical into electric power.

The formulæ are equally applicable to cylinder armatures wound gramme fashion and to drum armatures, provided we count not turns of wire but active conductors over the whole circumference of the armature. As regards two-pole machines, the formulæ are the same as found in every text-book on dynamos, but as regards multipolar machines, a little explanation is required, both as to the winding and as to the advantage or otherwise of using more than one pair of poles. To make the explanation clear, I must refer for a moment to the ordinary method of drum winding for two-pole armatures. When such a winding is illustrated in a text-book, the author takes care to show only very few conductors, for the simple reason that the diagram would be one unintelligible maze of lines if it were drawn so as to represent an armature as really made. To get over this difficulty I employ, instead of a diagram, a tabular statement of the winding such as you see on the wall. This particular table represents the winding of a drum armature having 100 active conductors.

Drum Winding.

The figures at the top of the vertical columns indicate the direction of winding, supposing the winder looks at the armature end on. The letter D signifies a wire, wound down or away from him ; and the letter U a wire wound up or towards him. The letters F and B, placed between the others, denote the front and back connections respectively. In modern machines these connections are not made of flexible wire, but are separate pieces, specially made to shape, and are generally of larger section than the conductor, so as to reduce the resistance of the armature as much as possible. One form of connector is on the table, both in pieces and built up. By referring to the winding-table, you will see that every wire is numbered ; and thus we can see at a glance how the ends of each wire are connected. The table on the wall refers to a two-pole machine, that on the slip in your hands to an eight-pole machine, wound so as to obtain the E.M.F. of the four pairs of poles in series. The printed table, giving the eight-pole winding, is almost self-explanatory ; but, to assist you in understanding the winding of these multipolar machines generally, I had this model prepared, showing a few of the conductors of a six-pole armature. This method of winding has been invented by Messrs. Scott and Paris, patents 4,683 and 6,261 of 1874. There are no internal cross-connections, the ends of the conductors being joined simply by connecting segments of the kind I have just shown you ; but with this difference, that each segment, instead of embracing half a circle, embraces only one-sixth of a circle. The winding goes in zig-zag, so to speak, round the armature, returning to the second wire in front or behind the previous starting-point. There are thus only two brushes required. The winding tables show, also, very clearly how the E.M.F. increases from wire to wire, and that the greatest difference of potential occurs between neighbouring wires at the diameter of commutation. The difference of potential between neighbouring connector segments is, however, limited to the E.M.F. due to the two conductors. The winding is used for machines intended to give high-pressure currents, such as are required in power transmission. When low-pressure and large currents are required, the winding is altered, so as to form overlapping loops on the armature, and for intermediate electromotive forces a combination of both methods can be used. But as these windings have no immediate importance for power-transmission, I shall not detain you with a description of them.

Now, as to the advantage of multipolar machines, such as the one which I illustrated on the screen. The field magnets are arranged perfectly symmetrical round the armature ; and thus the one-sided magnetic pull, consequent upon the employment of a single pair of horse-shoe magnets, is avoided. There is very little magnetic leakage, the machine being what is known as iron-clad ; and, as I have already shown, the E.M.F. is equivalent to that of several smaller machines, coupled in series. The internal diameter of the armature is very large, affording plenty of space for the ingress and egress of air ; and the weight of the machine is less than that of an equivalent two-pole machine. The most important advantage, however, is the

Digitized by Google

small armature reaction. Experience with large two-pole machines has shown that there is a limit to the size above which such machines are satisfactory. This limit depends, of course, on the speed and voltage, as well as on the output; but, roughly speaking, we may take it that, for moderately high voltage, and an output above 100 H.P., the multipolar machine is preferable; and we find, accordingly, that, for the transmission of large powers, multipolar machines are, as a rule, employed.

I have hitherto not made any distinction between motors and generators, because the difference between them is almost negligible. There are certain secondary effects which may be a little greater in one machine than in the other; but these are of so little importance that it will not be worth while to devote any time to their consideration. As a rule, a good generator makes a good motor. All we require to do is to set the brushes a little forward of the neutral line in the former, and a little back from that line in the latter. Now let us see what it is we must naturally aim at in putting up a transmission plant. At the generating end of the line we want as high an E.M.F. as we can get, because a high E.M.F. means large power and small percentage loss due to line resistance. At the motor end we want as large a torque or statical effort as possible, combined with a certain speed. But a glance at the formulæ will show that it is impossible to get speed without also getting E.M.F., which, in the case of the motor, must oppose the current, and thus the current actually flowing through the motor is that due to the difference between the E.M.F. of the generator and the counter E.M F. of the motor. This difference, divided by the total resistance of the circuit, gives the current.

The electrical power developed in the generator is the product of this current, and the E.M.F. in its armature. The electrical power converted by the motor is the product of the same current and the counter E.M.F. of its armature. It therefore follows that the electrical efficiency of the whole system is given by the ratio between the generator and motor E.M.F. The more nearly alike these two are, that is to say, the less E.M.F. lost in resistance, the greater will be the electric efficiency. Now, the smaller the current the less E.M.F. is lost in resistance; but to get power with a small current we must work at high pressure, and we thus find that, from the point of view of electrical efficiency only, the higher the voltage the better. There are, however, other things to be considered besides electrical efficiency, and if we take due account of these we find that for every case there is one particular voltage at which it is best to work.

Upon this subject I shall enter presently, but, before doing so, I must place before you some points in connection with the regulation of speed and power in transmission plants. Unless we can control the speed, and regulate the power given out at the receiving end of the line, the most perfect motor or the most efficient system is useless. Fortunately, however, electricity is not only a powerful transmitting agent, but also one that can be easily controlled, and my next task is to show you how this control is effected.

(To be continued.)

THE INCANDESCENT LAMP INDUSTRY.*

BY FRANK GÉRALDY.

The Chamber of Deputies, during the sitting of July 6th, voted a duty of 500 francs per 100 kilogrammes on all incandescent lamps entering France. M. Georges Berger spoke vigorously in favour of this tax being still higher, and he has been reproached both for his speech and for his vote. M. Berger has taken up the position of freetrader; he is president of the League for Defending Raw Materials. There was, therefore, something inconsistent on his part in demanding protection. This is true enough, but what will you? M. Berger has only acted in the same way as have several of his colleagues placed in the same situation, who have imitated La Fontaine's dog, which unable to protect his master's dinner resigned himself to eating his share. They saw very plainly that the Chamber was bent on ultra-protection, and although combating this bad policy they were afraid lest they should be betrayed into leaving their constituents unprotected in the midst of universal protection. I do not know if this was tactically good. Many industries which rely implicitly on protection will be greatly disillusioned when they come to enjoy it. It would perhaps have been better to have adhered to one's principles. The incandescent lamp industry in particular will, I think, gain but little by the duty just voted.

The incandescent lamp market has altered enormously during the last four years. Lamps were then commonly quoted at 5 francs, 4 francs and 4 francs 50 centimes being considered as reduced prices. It was felt that a reduction was sure to come, but it was not foreseen that it would come so quickly, and that it would be so large. To-day, incandescent lamps can be had for 2 francs 50 centimes, or 2 francs, and even less.

* From *La Lumière Électrique.*

Labour, as we know, enters largely into the manufacture of an incandescent lamp, and it was natural that the industry should at first take root in countries where labour was cheap, and the electrical industry, at the same time, sufficiently developed. Such countries were Germany and the neighbouring States. But once the reduction had begun, once it was seen that it was possible to manufacture more cheaply, it was pretty certain that France would take the field; and there are to-day French firms with a large turnout which are doing well, and which are not beaten by foreign producers. Hence, following the well-known law, prices no longer depend on external, but on internal, competition. Since the firms in question have succeeded in competing with the foreigner, it is evident that the cost of production is not sensibly higher than it is abroad. Moreover, cheapness is not everything; the quality of a lamp is naturally not without importance. Among the very cheap foreign lamps which flooded the market there were inferior ones, short lived, and burning with irregular brightness. People soon got disgusted, and took to lamps somewhat dearer, but much superior.

This seems to me to be the key of the position. It is impossible to return to former prices; they are low and will remain so. The protection granted amounts to about ·175fr. per lamp, and will not, I think, be sufficient to exclude foreign lamps. If it does succeed in doing so, French lamps will multiply, and home competition will bring down prices to the same level, because, after all is said and done, it is a possible price, and one which a large, well-organised industry should be contented with. The key to success will be the quality of the produc-. By quality I mean the general properties of a lamp, regular voltage, whiteness of light, long life, ease of fixing, strong construction, and other like essentials. Other more special qualities, such as satisfy the taste and requirements of the consumer, have to be aimed at. The public, indeed, has begun to have some taste in electric lighting matters. Only a little time ago it accepted all that was given it; great choice was not, indeed, then possible; to-day the public has seen, compared, and has its preferences. Certain styles of lamp, certain arrangements of filament, are in request. In Paris, at the present moment, fashion seems to favour looped filaments, and the look of the simple horse-shoe shape is considered cold. Lamps, the filaments of which are closely coiled, emitting light from a more restricted centre, and appearing more brilliant, are preferred, and, generally speaking, small-sized lamps are wanted.

Taste is also changing with regard to candle-power. Ten candle-power lamps were at first almost the only type asked for, because one such lamp naturally replaced a gas burner. Now people are beginning to take lamps of 16 c.p., and more, which is a good thing, because these lamps are in reality better and more efficient than the smaller units. The art of manufacture should be sufficiently flexible to be able to lend itself not only to meeting the present demands of the public, but probable developments. Future requirements, I repeat, ought to be foreseen.

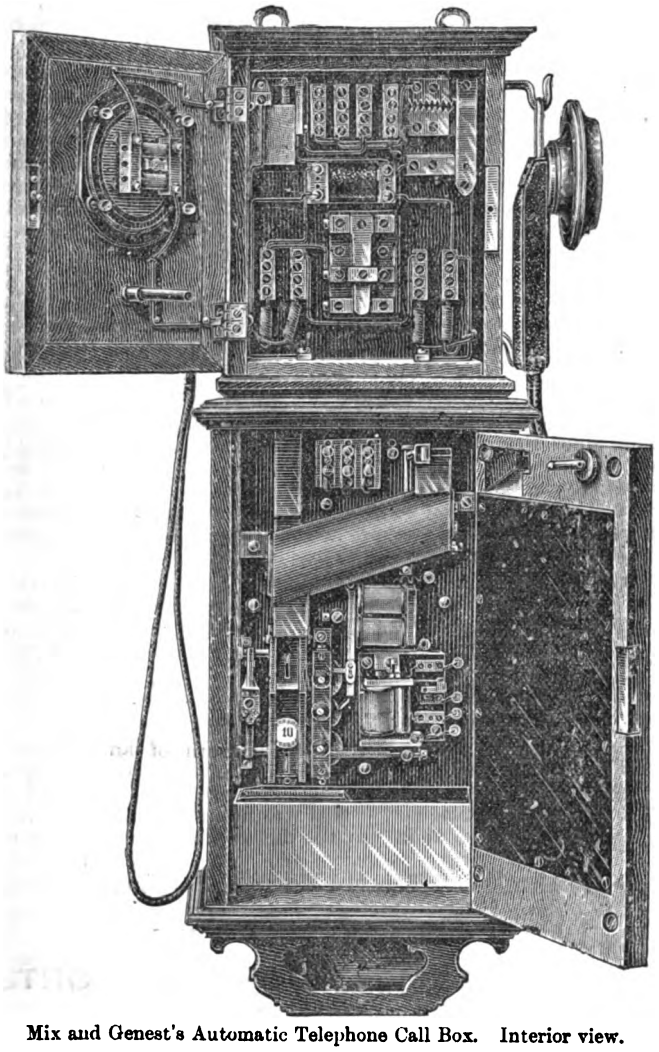
Up till now all improvements in lamps (but few in number, by-the-way) have only had for object increased strength and durability, and but little attention has been given to the lamp as a piece of machinery, that is to say, to its consumption of energy. All 10 c.p. lamps are from this point of view much the same, and consume about 4 watts per candle. I do not overlook the statements of many manufacturers that they have attained better results, and, as a matter of fact, when it is a question of a few lamps, one can obtain without much difficulty lamps which take 3·5 watts, and even less (I am talking of 100-volt lamps), but if we take a large supply we revert to the 4 watts indicated above. The fact is, lamp makers have not as yet succeeded in reducing the energy consumed without at the same time shortening the life; an important factor, owing to the high price of the lamp, and the manufacturer has been afraid to displease the consumer by sacrificing durability. But the simplest calculation shows that, taking into consideration the usual price of electricity in Paris (the light and cost being the same), a lamp taking, for example, 30 watts, and lasting 500 hours, would be appreciably more economical than one taking 40 watts, and burning 1,000 hours. It is somewhat difficult, it is true, to make good 10 c.p. lamps, running at 100 volts and taking 30 watts, even with short life; the economy that it has been found possible to effect up to the present is the least possible, and it is to be feared that it has not been apparent enough to be appreciated by the consumer. It must be admitted that the supply companies have not up to the present pushed the matter. As they supply energy by meter, it would seem as if they had no interest in doing so, and that so far as they are concerned it would be better to use lamps consuming much more current. If this idea is traced to its origin, and found to have any weight, it is not to be doubted that after some time the intelligent interest of the company will be found to be identical with that of the consumer. After all is said and done, it is the consumer who has to be satisfied, and this object will be attained by giving him more light at less cost. The need for light, like other wants, is not limited. At any rate, with all our methods of lighting, we are very far from equalling the

Digitized by Google

brightness of daytime which might be assigned as a limit. The more we give, the more will be taken. Supply companies need not fear, therefore, to see their receipts diminish if more efficient lamps are used. On the contrary, it is almost certain that they have in this a good way of increasing their revenue. In any case, it is one of the chief conditions of superiority for a lamp maker. I do not ignore the practical difficulties to be encountered, but they are by no means insuperable, and I am of opinion that in the present state of the market success is to be attained in this way.

THE MIX AND GENEST AUTOMATIC TELEPHONE CALL BOX.

The idea of an automatic telephone call box on the "nickel in the slot" principle is a very fascinating one to the playful public and ingenious inventor, and no doubt if a cheap and reliable instrument were forthcoming, and the inertia of the telephone interests



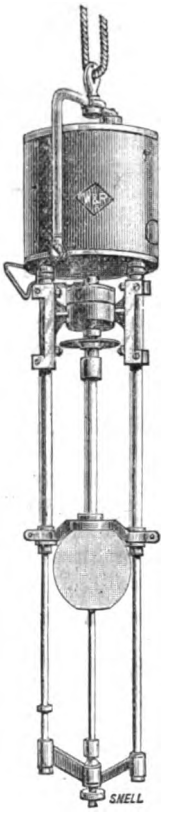
Mix and Genest's Automatic Telephone Call Box. Interior view.

could be overcome, there would be a large field for such a contrivance. At present, the same heavy annual rental has to be paid by a subscriber who only uses his telephone once or twice a day and by a stockbroker whose daily "calls" are incessant. A more equitable, and, probably, a more profitable system to the Companies would be to make a small annual charge for each telephone installed, and to tax each conversation. By this means a larger, but less talkative and discontented, *clientèle* would be obtained; and if the automatic principle were employed, a book-keeping staff of impossible dimensions would not be required.

The well-known firm of Mix and Genest, of Berlin, are now having an automatic call box tested, which they claim solves the question. The internal arrangement of the apparatus is shown in the accompanying figure. Upon a coin being inserted into the slot, it passes through the usual testing arrangement. Should it fail to pass this test, it is rejected; but, if it proves satisfactory, it passes on, and rings up the exchange. If the caller is informed that the desired connection cannot be made, he has only to press a white stud, and the coin is released, and falls to the refunding box. Should, however, the required connection be made at the exchange, the current which then passes causes the coin to fall into a groove, where it remains until the signal at close of the conversation is given, when it is released by a magnet, and allowed to fall to the cash-box, pressing *en route* a lever, which breaks all contacts. Should, however, the closing signal be omitted, it is obvious that the coin will remain in what may be termed the "talking position." In order to prevent loss from this cause, a lever is provided, by means of which an armature is moved, as if electrically, upon insertion of the next coin, and the one remaining in the instrument falls to the cash-box before the other has passed through the testing arrangement.

THE MIDGET ARC LAMP

Messrs. Woodhouse and Rawson are introducing a small arc lamp which burns in a very satisfactory manner, and, if it is found that it does not need much cleaning, should be very useful for lighting shops, &c. Instead of endeavouring to simplify the mechanism, as has been done in several small arc lamps, the feed is given by clockwork, and a pendulum escapement is controlled by a pair of differential coils. The lamps can be wound for running in series or in parallel, or with alternating currents. The lower carbon holder gives the feed, and is hung by a chain, which is released by the clockwork, and passes through and is protected by side tubes, in which the rods supporting the lower carbon slide freely. The arc is struck by a short magnet



on the upper carbon holder. The lamp takes a current of 5 amperes, and requires 45 volts. The candle-power is said to be 250, but, on making inquiries, we learn that Messrs. Woodhouse and Rawson have not yet made photometric measurements. We are also informed that 11mm. cored carbons are used for the upper, and 7mm. solid for the lower, and that they last for six hours. The 45 volts recommended should give a fairly long arc, and when a clear view of the crater is thus obtained there should be no difficulty in getting one candle-power per watt in a small lamp. A feature of the Midget Arc Lamp is a globe of only 3in. diameter. The effect is good, but we are inclined to attribute a good deal to the novelty, for with ordinary 10-ampere lamps it is well known that the public think much more of a lamp if it has a 20in. globe than if a 12in. one is provided. We cannot understand why a small globe prevents "any depth of shadow," and minimises any complaint which may be urged against the inequality of the distribution of the light." The economy, light for light, over ordinary glow lamps is so great that these little arcs, which are too small to be offensive, shou'd meet with great success.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 18, 1891.

The Edison Lamp Case.—The event of the present week is the decision of Judge Wallace, of the United States Circuit Court, in the incandescent lamp suit. This was announced last Tuesday, and was of a character to spread consternation among the lamp manufacturers, and to surprise all but the most sanguine of Edison's supporters. It virtually amounted to a declaration that Thomas A. Edison was the real inventor of the incandescent lamp, and was entitled to protection in his rights of invention, even to the extent of monopoly. From beginning to end the case has been a singular one; Edison's moral rights were apparently much stronger than his legal ones, so that it seemed almost impossible that the patent under which suit was brought could be sustained broadly; nevertheless, it has been, though in a somewhat illogical manner. Edison unquestionably introduced the use of carbon conductors having a considerably greater resistance than any that has previously been employed for incandescent lamps. The result was an immediate change in general practice, so that all the lamps made to-day are in this respect close imitations of the Edison construction. This was not, however, the real point at issue in the suit, for, granting Edison's priority in the use of high resistance carbon filaments, the real point to be decided was, first, whether this change in practice involved patentable novelty; and, second, whether it was covered by the famous second claim on which the decision turned. In Judge Wallace's opinion, as rendered, the first question was almost neglected, the evidence being brushed aside almost as if it had not existed. The second question was answered in the affirmative, in spite of a considerable amount of evidence brought to show that at the time of the application such a construction of the claim was not contemplated. Of the usefulness of Edison's construction there is no question, but this is a very different thing from affirming its patentability under the laws. The ground apparently taken by the Judge was that, in view of the importance of Edison's work, he should be given full rights in the matter, despite the technical points that could be raised. The attack upon the patent was purely technical in its character; the defence, for the most part, general. The Sawyer-Man Company is, of course, the one [most affected] by the decision. The Thomson-Houston Company, now working under royalty to the Sawyer-Man patents, might be able to transfer its allegiance to the Edison Company without any considerable loss. The ultimate result may be to throw the manufacture of lamps either wholly into the hands of the Edison Company, or into the hands of two or three prominent manufacturers. An appeal is, of course, pending.

Electric Traction at Boston.—Several electric railways are under construction just now, and a large amount of comfort may be gained by the friends of electric traction from the contemplation of recent reports from the West End Railway of Boston, Mass. During the month of May last the electric cars on this system ran 376,321 miles, at a cost for total operating expenses of $84,163. The total expenses per mile run were 22·36 cents; the earnings per mile run, 38·43 cents, and the net earnings, 16·07 cents. The horse cars on the system ran 1,940,683 miles, at a cost for total operating expenses of $269,556; they earned per mile run, 34·22 cents, and cost for expenses per mile run, 24·62 cents; giving net earnings of 9·06 cents per mile. These are instructive figures, and are on a sufficiently large scale to be worthy of considerable confidence. The West End service covers about 18,000,000 car miles per year, and from the data just given it is evident that the change from horses to electricity is more than worth the extra expenditure for plant.

BOOKS, &c., RECEIVED.

"The Arithmetic of Electricity." By Dr. T. O'Connor Sloane. (London: E. and F. N. Spon.)

"The Arithmetic of Electrical Measurements." By W. R. P. Hobbs. New edition. (London: Thomas Murby.)

TRADE NOTES AND NOTICES.

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all, Vol. I., 20; Vol. II., 18), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

TENDERS INVITED.—It will be seen by our advertisement columns that the Southampton Harbour Board invite tenders for lighting the Royal Pier by electricity, and forproviding and fixing two electrical cranes on the Town Quay. Plans may be seen at the office of the engineer, Mr. J. G. W. Aldridge, 9, Victoria-street, London, S.W., from whom specifications and forms of tender may also be obtained. Tenders are to be delivered at the offices of the Harbour Board, Town Quay, Southampton, not later than Monday, August 24th.

———Tenders are invited, up to August 7th, for the erection of plant for the electric lighting of the town of Cuenca (Spain).

———Tenders are invited by the municipality of Zanora (Spain) for the erection and working, for a period of 25 years, of a plant for lighting the town by electricity. Tenders will be received up to August 15th, and a deposit of £100 will be required.

ADMIRALTY CONTRACT FOR ASBESTOS GOODS.—The United Asbestos Company (Limited) has, for the seventh time, secured the contract for the supply of all kinds of Asbestos goods required for use in Her Majesty's Navy, during the ensuing twelve months. The contract includes the supply of the following brands of the United Company's well-known manufactures:—"Victor" block packing (square and round), hard spun yarn packing, "Victor" metallic sheeting, tape, rings, ovals, &c., for steam, manhole, mudhole, hydraulic, and other joints; pure tape and cloth for pipe and boiler covering and other purposes; millboard and sundries.

THE ELECTRICAL ACCESSORIES COMPANY.—We are informed that this Company is now in course of reconstruction, ample capital having been provided to enable the Company to increase its manufacturing capacity.

KIRKALDY'S LIVE STEAM FEED WATER HEATERS.—Some experiments on a paddle steamer were recently recorded in the *Engineer*, which show that under certain circumstances live steam may be used with advantage for heating feed water. The use of hot feed for preventing unequal expansion is obvious, but it is not clear how any economy of fuel can be expected. The experiments, however, showed a higher boiler pressure and increased speed of the engines, while the firemen appeared to be less pressed.

THE RECHNIEWSKI DYNAMO.—Messrs. E. L. Berry, Harrison and Co., of Lyric Chambers, Whitcomb-street, W.C., have been appointed sole agents for the Rechniewski machine which obtained the only gold medal for dynamos at the Paris International Exhibition, 1889. It has been much talked of on the Continent, and is now for the first time introduced to the home trade. A pamphlet and price list has been framed for general information.

SMITH'S PATENT AIR CUSHION EAR PAD.—This handy little invention is for use with an ordinary telephone. The elastic cylindrical part of the ear pad is stretched over the mouth of an ordinary telephone receiver, so that the inflated part forms a ring. When the telephone is in use the inflated ring beds against the user's head, and forms a perfect sound chamber. These pads are 4s. per pair, and are sold by Mr. Mogridge, New Inn, Hall-street, Oxford.

COMPANIES' MEETINGS & REPORTS.

Globe Telegraph and Trust Company (Limited).

The eighteenth ordinary general meeting of the Globe Telegraph and Trust Company (Limited) was held on Tuesday, at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. William Payton) having read the notice calling the meeting, and the minutes of the last general meeting, the report of the Directors was taken as read.

The CHAIRMAN: Before I ask you to pass the resolution approving of the report, I will make a statement giving you some idea of the working of the Trust during the last 12 months. During the existence of the Company the dividend on the ordinary shares has been progressive. It has never fallen below 2⅜ per cent. That was in 1887, which was the time of the fierce Atlantic competition. Since that date the dividend has been augmented to 3½ per cent. in 1888, 4⅝ per cent. in 1889, 5 per cent. in 1890, and I am pleased to say that, though we do not propose a large addition this year, still, it is an addition, as we propose to declare to-day a dividend of 5¼ per cent. This shows, as I have said, a gradual and steady increase. The average dividend paid since the commencement of the Company in 1874 is £4. 7s. 1d. per cent. on the ordinary shares and 6 per cent. on the preference shares, and these, taken in conjunction, give a uniform dividend throughout our working period of 18 years of £5.3s.6d. per cent., which would seem to show that the investment is a steady, pro-

Digitized by Google

gressive, and good one. The Company's holding in the Eastern Telegraph Company, of close upon £1,000,000 of stock is one element of prosperity. They give us on our investment price £6. 7s. 2d. per cent. The Eastern Extension Company, in which we have again a very large holding—something like £560,000—give us £6. 16s. 5d. per cent., which you will observe is also a very good investment. These two items in our accounts give us a stamina which enables us to keep up our ordinary dividend and to slowly increase it. The Anglo-American Company, in which we hold over £1,000,000—namely £1,117,354—yields us only £3. 0s. 4d. per cent.; and the Direct Company, in which we hold £198,900, gives us a return of £6. 2s. 11d. per cent. The Anglo is the weak element in the Trust at the present moment, but I think there is a possibility of improving that investment, and probably by the time I have the pleasure of meeting you again, if I am spared for another year, I shall have the satisfaction, I think, of showing you an improvement in that respect. At all events, we never cease to think as to the best way that we can increase the value of your property and augment your dividend. All the other securities, with the exception of some minor items enable us to maintain our dividend. The Brazilian Submarine Company's shares cost us par, and pay us, on the £254,870 of stock which we hold, at the rate of £8. 10s. per cent. You will, therefore, see that we have some good things if we have some things that are not so good, and we have some things which are very good indeed, qualifying the difference in other respects. The report is full and explicit, but as regards the money received from the German Government, re-investment has been made in 1,850 shares in the Western Union Telegraph Company, and 2,050 shares in the American Cable Company. In mentioning these two investments I may say that we have always tried to give rather an international character to our investments; and as I have had the opportunity of seeing something of the American system of telegraphy—more particularly the Western Union—I am quite satisfied that their property is a most valuable one. It would probably have been better, in regard to the cables they have now in hand, if they had let this matter alone, and have kept to the land system; but they guarantee the property that we have in their submarine cable 5 per cent., and my impression is that no better guarantee or safer investment can be found. In regard to their own property, it covers an enormous area, and it is a prosperous and successful Company, and must continue to be so, because telegraphy is one of those introductions into more modern life and civilisation which must go forward. It cannot go back, for there is a demand for it; and as the world grows, so will the telegraphic interest increase. We have a small loss in exchange on the money we have invested in this particular way. The great bulk of this money came to us from the German Government. The par value of the money paid in Berlin is subject to exchange here, as you know, and that amount we have lost. The amount which it cost to bring this money home was about £1,100, but we added that to the value of the property, and it does not in any way interfere with our capital. We debited this loss to the cost of our new investments, treating it purely, on the advice of your auditors and accountants, as a capital item. There is the more reason for this course, because the securities hitherto realised by the action of the German Government have produced more than they cost, and the market value of the securities now held exceeds the aggregate cost appearing on our present balance-sheet. If we take the statement of the shares held, shown on page 6 of the accounts, and take the cost at the lowest market price, and then, again, at the highest market price, and thereafter strike an average, we shall find a mean rise in value on our stocks of £343,738. I want to draw your attention more particularly to this point. We have a large interest in the Anglo-American Company, the Eastern Company, the Eastern Extension Company, and in the Brazilian Companies; but taking all our stocks, good and bad together—taking the whole thing—we show a profit upon them at the present day of something like £343,738. There could be nothing more satisfactory than that, in my opinion; and it enables us to go on steadily. We have no reserve fund. We give you all we get, and the success of the other companies is very important to us. We are large shareholders in all these companies, and we naturally keep ourselves in touch with them, so that we are a strength to them if they are strong and good in their management, and we make them weak if we find that they are not managing as they ought to do. You will, therefore, understand that the Globe Company has considerable control over the companies now in existence; but those companies are well managed, and are successful. The Anglo-American Company gives us a low dividend, but, as I have said, it may be possible to improve the investment we have in the Anglo and the Direct Companies, and I hope when I meet you again that I shall be able to draw your attention to this subject. We should have had a full Board here to-day if Mr. Ford had been present. Mr. Ford is one of our early colleagues. He has always taken a deep interest in the undertaking, but, unfortunately for us, he has passed through that terrible scourge of influenza, and somehow or other it is clinging to him in such a way as to unfit him from being here to-day. I express my regret personally at this, and I am sure that you will all join with me, and sympathise with Mr. Ford in his absence. The Globe Company was instituted, as you know, to yield an average return by spreading the risk over a number of investments. For instance, a man holding Anglo-American stock, if he had not taken Globe stock, would now be receiving about 3 per cent. instead of 5¼ per cent., which he will now receive from the Globe Company. A great number of Anglo shareholders came into the Globe, and this has been the result to them. This is one of those things which probably you may not have sufficiently thought about—which may not have occurred to those who make their own averages. The Globe Company has made the average for them in many cases, and I think you will admit to-day that you are benefited by the Globe doing so instead of making your average for yourselves. We meet only once a year, and really it is very difficult to make up a speech which will interest you beyond giving you these simple facts. We confine ourselves, probably, more to the facts of the thing than to the sentiment which we might introduce, but this I must say, that while I would like to see a larger gathering of our constituents, yet that their absence shows the confidence which they have in us. We have a great many shareholders.

The SECRETARY: Eight thousand five hundred.

The CHAIRMAN: We have 8,500 shareholders in the Company, and I think you will admit that the confidence of that large body must be very great indeed to-day when they are represented by such a small number as we now see here. While I should like to see a larger number of shareholders present, I have the satisfaction of knowing that they trust us. When a company is prosperous, it does not require much talking from a Chairman but when a company is in difficulties a any given Chairman might have a greatdeal to do in order to make black appear white, and white appear black. We have nothing of this kind in this Company. Our task is to tell you exactly how the business is going on, and that you may feel when you retire from this meeting that the investment which you have made in this Company is in good hands, and that the chances are above the average of your receiving your dividends regularly, and probably of having them increased if slowly. I will now move the following resolution:—

"That the report and accounts for the year ended July 18, 1891, submitted to this meeting be, and they are hereby, received and adopted, and that a dividend be now declared, payable on and after this day of 3s. per share on the preference shares, less income tax, and of 4s. 6d. per share on the ordinary shares, income tax having already been deducted, making, with previous payments, a total dividend for the year of 6 per cent. on the preference shares, less income tax, and of 5¼ per cent. net on the ordinary shares."

That is the resolution which I now move.

The Marquis of TWEEDDALE: I beg to second the resolution.

The CHAIRMAN invited discussion, but no shareholder rising to address the meeting, he put the resolution in the usual way, and it was declared carried unanimously.

On the motion of the CHAIRMAN, seconded by Sir JAMES ANDERSON, the Marquis of Tweeddale was re-elected to his seat at the Board, as was also Mr. James Pender, on the motion of the CHAIRMAN, seconded by Sir HENRY D. GOOCH, Bart.

Mr. C. BURT then proposed the re-election of the auditors, Mr. John George Griffiths (of the firm of Messrs. Deloitte, Dever, Griffiths, and Co.) and Mr. Wm. Griffith, B.A.

Mr. JOSEPH KING seconded the motion, which was unanimously adopted.

Mr. W. GRIFFITH, in acknowledging his re-election, said that he could speak confidently as to the state of the book-keeping and as to the securities. Everything was in good order, and he thought they had strong grounds for hope in the future.

The CHAIRMAN having intimated that that closed the business of the meeting,

Mr. GRIFFITH proposed a vote of thanks to the Chairman and the Directors. There was, he said, no need for him to say much in support of the vote. They had themselves witnessed the urbanity and the ability of the Chairman; and it was a very strong argument in favour of the management that out of 8,500 shareholders there should be so few present. The public reputation of Sir John Pender was great, and was not confined to England, but extended over Greece, Portugal, Spain, and all the other countries which had loaded him with honours—honours not equal to those which had been conferred on their Chairman by her Majesty, but certainly honours which showed the esteem in which Sir John was held throughout the world. He was sure that few had done so much for commerce as their Chairman and those who had brought before the world the astonishing and most useful discovery of the telegraph; and they all knew what a leading part Sir John Pender had taken in the institution of telegraphy and its subsequent improvement, both in the Atlantic and the East. It was a subject of great congratulation to the shareholders to have a gentleman at their head who stood so high in the public estimation, and whose character was so calculated to improve the position which their stock held in the market.

Mr. KING seconded the resolution, which was unanimously adopted.

The CHAIRMAN: On behalf of my colleagues and myself I beg to return you thanks. It is in one way very pleasant to hear Mr. Griffith speak as he has just done, because he knows thoroughly the root and growth of this telegraph system. Only the other day he was for some hours down in the strong room examining our securities, and I think that those securities must have left a very good impression upon Mr. Griffith's mind. I think we are indebted to the real soundness of the Company's investments for the very pleasant and complimentary remarks Mr. Griffith has made. You know that he can say some very hard things. I have heard him do so, and say them in a manner which makes them felt by those to whom they are addressed. At the same time he can say some kind things, and he can do so speaking from the best authority—his own knowledge of our affairs—and we accept with the greatest pleasure the kind remarks he has made to-day. On behalf of my colleagues and myself I thank you for this renewed expression of your confidence, and you may rest satisfied that as long as these gentlemen sit on this side of the table your interests will always be their first consideration.

The proceedings then terminated.

The Telephone Company of Austria (Limited).

The eighth ordinary general meeting of this Company was held yesterday, at the offices, 53, New Broad street, E.C., Mr. Henry Grōwing, Chairman of the Company, presiding.

The SECRETARY (Mr. Richard Rodgers) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, the figures, which you will have seen

Digitized by Google

in the balance sheet, showed that the profits were again ample to pay the 5 per cent. interest on our debentures, and the 6 per cent. dividend to which the holders of the preference shares are entitled. After providing for these charges the balance is left of £4,485. 18s. 9d., which, under ordinary circumstances, would go as dividend to the ordinary shares. The state of prosperity of the Company as a company is, therefore, undoubted, and I will now proceed to the paragraph which refers to this surplus, and at the same time to the Company's future. It is as follows:—"In view of the expiration, in October next, of the Company's concessions, negotiations with the Austrian Government as to the future of the Company have been in progress for a considerable time past. These negotiations are now approaching their final stage, and the result will be brought to the knowledge of the shareholders without delay, Under these circumstances your Board do not recommend at present the payment of any dividend on the ordinary shares." Since this report was issued these negotiations has advanced a step further, and a telegram appeared in one of our leading morning papers on Tuesday last, dated Vienna, Sunday night. This telegram gives the position so accurately, that we can hardly doubt that the information was supplied from official sources. The Board, therefore, feel called upon to enter into this question more fully than they would otherwise have done pending the negotiations. The facts as stated are, as I have said, correct, but the expression used that we demanded compensation to the extent of £160,000, is misleading, unless it is added that we demand this compensation in return for a very heavy capital outlay amounting to about £100,000, in constructing, equipping, and bringing to their present state of perfection the eight exchanges which we possess in the Austrian Empire, and for the goodwill of the business built up during the last 10 years. The telegram might also have added that it was under the most trying circumstances that this business was created, and that all the energy, resources, and perseverance at the command of the Board were required to produce the results attained. These results were well known both to the proprietors and to the Austrian Government, to whom we are now paying some £3,000 per annum in royalties alone, not to mention a large amount in rates and taxes, while our revenue, as the result of our large capital expenditure, shows a net profit of some £9,000, or, not deducting the royalties, £12,000 per annum. This large and prosperous undertaking the Government now wishes to take over, and, according to our reading of the purchase clause in the concessions—a reading which is shared by one of the most eminent lawyers in Vienna—the basis for fixing the purchase price is, among other stipulations, the amount of net revenue of the year preceding the purchase. The Government, however, interprets the purchase clause differently, and insists that it only applies during the continuance of the concessions, and not after the latter have come to an end, namely, on the 14th October next, the argument being that, as the Company would have to stop business on the 14th October, the revenue then ceases, and cannot consequently be taken as a basis. Such is the present legal aspect of the matter, but we have it from the present Minister of Commerce himself that the question will also be viewed by him from an equitable point of view; and we are certain that His Excellency will be the first to admit that a concession for so short a term as 10 years cannot possibly give to those who work it an opportunity of recouping themselves out of profit for any of their outlay. His Excellency will also admit that this new and extremely valuable means of communication, as introduced by us into the Austrian Empire, has met not only with the strong support of the public, but the very fact of its having met a public necessity, and, at the same time, created a new and ever increasing revenue to the State, has determined the Government to acquire it of the State. I may here say that neither money nor pains have been spared to make the service one of the best, if not the best, in Europe, and that the authorities themselves have really expressed their satisfaction to us on the subject, and commended us in an official document, as recently as January last, for the loyalty with which we have served both the public and the State. I may also add that to construct and equip afresh what we have constructed and equipped in the eight towns would cost the Government not less than the sum we are asking for, not to mention that it would take at least three to five years to get the whole of the exchanges into such perfect working as they are now. Our demand, therefore, is not unreasonable. Under these circumstances, your Board refuse to believe that the Austrian Government will deal otherwise than honourably and equitably with us, and that this opinion also prevails in influential quarters in Vienna was shown by the concluding words of the speech of Dr. Russ, when reporting on behalf of the Budget Committee on the advisability of the State purchase of the telephone nets. The following is a translation of the words:—"I am of opinion that private capital, invested in good faith, and honestly employed, should experience no damage through the acquisition by the State." We are most ably represented in Vienna by Dr. Weissel and Mr. R. Howard Krause, but in order to give every support to the negotiations they have been carrying on, three of your Directors have recently visited Vienna in order to lend their personal aid towards a satisfactory settlement. Since then the Government have made an actual offer, which, however, is unacceptable, and some of your Board have, therefore, determined to again proceed to Vienna in order to facilitate an understanding. You will gather from these observations that nothing will be omitted on our part to conduct this difficult business in the most friendly manner possible, for the Government can have no possible reason for frightening English capital and enterprise out of Austria. On the contrary, we look to the Government for the protection of English capital legitimately employed, and it is to be hoped that it will be protected from all such undeserved attacks. He concluded by moving the adoption of the report and accounts.

Mr. C. L. W. FITZGERALD seconded the motion, which was carried unanimously.

On the motion of Mr. FITZGERALD, seconded by a SHAREHOLDER, Mr. Grëwing was unanimously re-elected to his seat at the Board.

The auditors, Messrs. Deloitte, Dever, Griffiths, and Co. were also re-appointed on the motion of Mr. VANZELLER, seconded by a SHAREHOLDER.

Mr. A. H. BAKER proposed, and Mr. VANZELLER seconded, a vote of thanks to the Chairman and Directors, and the former having briefly acknowledged it, the proceedings terminated.

Telephone Company of Ireland (Limited).

The twelfth ordinary general meeting of this Company was held on Wednesday at the offices of the Company, Commercial-buildings, Dame-street, Dublin, under the presidency of Alderman Dillon.

The SECRETARY (Mr. W. F. Bottomley) having read the notice convening the meeting,

The CHAIRMAN moved the adoption of the report, which will be found below. He said the report showed satisfactory progress in the Company's business, and in telephoning generally. They had had an increase in subscription of about 15 per cent. on the year ended, notwithstanding the serious accident which disrupted traffic for a considerable time at the end of last year. It was satisfactory to say that the expenses occasioned by the accident had been defrayed without resorting to capital. They expected, however, this year they would make a considerable step in advance by the opening of the exchange between Dublin and Belfast. This they anticipated would be completed before October 1st. As arranged, the tariff from Dublin to Belfast would be fixed at 1s. for a message lasting for three minutes—that was, that a person communicating with Belfast now could send a telegram which would cost 6d. per twelve words and receive a reply costing 6d. more for twelve words—1s. in all. By the telephone he would have an opportunity of exchanging for the same price of 1s. his views with his correspondent in Belfast to the extent (if he talked fast enough) of something like 300 words. That they considered to be a very important development. The tariff from Dublin to towns inside their own district, which included the county of Louth, and therefore the towns of Dundalk and Drogheda, would be only 6d.—that was 3d. for a message each way. Of course, one could not predict what might result from the opening up of such a new system as that; but if one was to judge by the number of telegraphic messages which were exchanged between Dublin and Belfast, and between the intermediate towns, the results now would be very satisfactory to the Company for the small amount of capital which had had to be made. They had been able to arrange, as the report showed the shareholders, for working capital for this development and for the general business of the Company, on satisfactory terms. He did not know that there was anything else in the report which called for any comment. Their accounts they considered showed very satisfactory results of the working, and they hoped they would meet with the approbation of the shareholders,

Mr. ARTHUR DUDGEON seconded the motion.

Mr. HUMPHREYS asked for some information with regard to the dividend on the preference shares, which he said was half a year in arrears.

The CHAIRMAN: It is hardly fair to say they are in arrear. The dividend warrants will be issued this week.

Mr. HUMPHREYS: But with respect to the dividend that will accrue next month?

The CHAIRMAN said the account clearly showed that it would be paid, because they had an earning power of more than twice the preference dividend, but they had considered at present that while this Company was in a transition state, as, owing to circumstances known to the world in reference to patents, it undoubtedly is, they considered it better to pay the whole preference dividend at the end of the next six months. They were going to pay the dividend in arrears now, and the year's dividend at the end of the year.

The resolution was carried.

The CHAIRMAN moved that Mr. Gilbert Cockburn be elected a Director of the Company, which was seconded by Mr. DUDGEON, and carried.

Mr. JAMES EVANS moved that Mr. J. M. Kean be appointed one of the auditors, and that the joint remuneration for the auditors appointed by the Company and by the National Telephone Company be fixed at 50 guineas per annum.

Mr. HUMPHREYS seconded the motion, which was adopted, and the meeting terminated

---

The following is an abstract of the report of the Directors of this Company for the year ending December 31st last:—

The number of wires, exchange and private, under rental upon December 31, 1889, was 1,309. On December 31, 1890, the number was 1,473, being an increase of 164 for the year. In the month of November last a very severe snowstorm caused a partial breakdown of the Company's system in Dublin. The exceptional damage caused by this snowstorm was due entirely to a very humid state of the atmosphere, coinciding with a temperature just over freezing point, against the consequences of which it is impossible to provide; the aqueous vapours congealing rapidly around the wires, increasing their weight, and ultimately breaking them. This unfavourable combination of extreme humidity with freezing point fortunately occurs only at very long intervals, the last occasion having been in the year 1885, when it was confined to the district lying along the south side of the Bay of Dublin, and the damage was then localised to the Kingstown and other lines in that direction. The entire cost of making good the damage has been debited to the reserve fund, which was established for the specific purpose of providing against any such contingency, and the opportunity was taken to replace nearly the whole of the old iron wires with wires of silicium-bronze, the cost thereof being also debited to

Digitized by Google

the reserve fund. The damage was not wholly repaired during the year 1890, but the balance of the cost appears in the supplemental accounts.

In their report presented to the shareholders upon April 26, 1890, the Directors stated that additional capital was required for the extension of the business of the Company, and for the establishment of the proposed through trunk line connection between the telephone exchanges of Dublin and Belfast. It was also stated that for the purpose of providing the additional capital required, 10,000 new Five per Cent. Preference Shares were offered to the shareholders in proportion to their respective holdings; also that the subscriptions to these new shares had not been sufficient for the purposes required (1,407 shares only out of the total of 10,000 offered having been applied for), and the Directors were then authorised to issue Five per Cent. Debentures to the extent of £10,000, part of an aggregate of £25,000. These debentures were also offered to the shareholders, but up to February, 1891, 29 debentures (£2,900) only had been taken. It, therefore, became necessary for the Directors, acting under the powers conferred upon them by the resolution authorising the issue of the said debentures, to place privately a sufficient amount to meet the requirements of capital expenditure. Accordingly, the shareholders having been informed of the circumstances by circular letter, dated 25th May last, the necessary authority was given to the Directors, at an extraordinary general meeting held upon the 2nd June, to make a further issue of debentures for £12,100, bringing the total, including the £2,900 previously issued, to £15,000. These debentures for £12,100 produced, after payment of commission, &c., a net sum of £10,995. The Company, having thus been placed in possession of the requisite funds, are now, in conjunction with the National Telephone Company (Limited), proceeding as rapidly as possible with the erection of the trunk lines, not only to connect the telephone exchanges of Dublin and Belfast, but also to afford telephonic conveniences to the intermediate towns. It is expected that the lines will be open to the public on October 1st next.

One of the principal master patents expired in December, 1890, a second patent expires at the end of this month, but the National Telephone Company claim that other patents do not expire till 1893. This Company is entitled to a reduction of the instrument royalties as these respective patents expire, commencing from December last, and, in accordance with the terms of the agreement between the United Telephone Company and this Company, the amount of such reduction will be settled by arbitration. The accounts now submitted are, therefore, subject to adjustment, according to the decision of the arbitrator. So soon as the last of the patents expires, and the Company is entirely freed from payment of the royalties for the use of the instruments, it is proposed to reduce the tariff. It may reasonably be anticipated, however, that in a very short time after such reduction the revenue will be sensibly increased, and the Company's business largely developed, in consequence of the adoption of such lower tariff.

In view of the increase in the number of subscribers, and in the number of calls, and of the large increase it is expected will accrue from the connection of the telephonic exchanges of Dublin, Belfast, and intermediate towns, together with the establishment of new exchanges on the northern lines, it will be necessary to entirely re model the Dublin centre. For this purpose a convenient site has been obtained, upon favourable terms, from the Corporation of Dublin; and within the current year plans will be matured to afford the necessary accommodation. In these circumstances, it is essential that the Directors should retain in hand sufficient funds to prosecute the business to meet current demands from the public; and in view of the expiration of the patents, and having regard to the transition state in which the Company is consequently placed, it is considered that the best interests of the shareholders will be studied by expending, as far as possible, current revenue upon the necessary works to further develop the Company's business. For obvious reasons it is undesirable to attempt to place additional capital at the moment. The balance to credit of the revenue account is ample to pay not only the entire preference dividend, but would enable the ordinary shareholders to receive a considerable sum as dividend upon their shares, but it should be unnecessary to point out to the ordinary shareholders that their interests are best conserved by an increase in the gross and net revenue, and by the avoidance of the issue of additional capital upon terms other than those which are justified by the soundness of the Company's business. It is, therefore, proposed to pay only the preference dividend for the year ended December 31, 1890, and, after making the usual provision for the reserve fund, to carry forward the balance. It is anticipated that by adopting this course, with the marked improvement which may reasonably be expected in the Company's business in the next year, the Directors may be enabled to place the remainder of the preference shares at par, and thus permit of the debentures being paid off, and the capital account being placed upon a more satisfactory footing.

It will be observed that the amount standing to the credit of the net revenue account as upon December 31, 1890, including the balance brought from last account, amounts to £4,950. 10s., against £4,459. 4s. 10d. for the year 1889. Out of this sum there has been paid an interim dividend upon the preference shares for the half-year ended June 30, 1890 (£1,137. 17s. paid in July last), leaving an available balance of £3,812. 13s., as shown in the balance-sheet, which the Directors propose to allocate as follows:—For the payment of the debenture interest, £49. 4s. 3d.; for the payment of balance dividend upon the preference shares for the second half of the year, £1,153. 1s. 8d.; and to place to the credit of the reserve fund £464. 13s. 6d. (being 10 per cent. of the net profits of the year), carrying forward the balance of £2,145. 13s. 7d. to credit of the current year.

The Directors regret to record the death of their colleague, Mr. Hermann G. Erichsen. They also regret the resignation of Mr. Robert Worthington, owing to pressure of business. Mr. Gilbert Cockburn has been elected by the Board as Director, in place of the late Mr. Erichsen, and his election is submitted to the shareholders for approval. The auditor, Mr. John M. Kean, retires at this meeting, but is eligible for re-election.

Crompton and Co. (Limited).

The third annual general meeting of the members of Crompton and Co. (Limited), was held at the City Terminus Hotel, Cannon-street, on Wednesday last, Mr. R. E. B. Crompton presiding.

The SECRETARY (Mr. Francis R. Reeves) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said: I have now to move:—

"That the Directors' report and statement of accounts for the year ending March 31, 1891, be, and the same are, received and adopted."

With respect to the statement of accounts, I think the shareholders will agree with me that the balance of net profits, £13,030, shows a satisfactory rate of increase on the balance of the previous year, and justifies the remarks which I made at last year's meeting as to the probable steady increase of the Company's business. During the year we have executed several important contracts, and our turn over has very largely increased, but, as explained last year, these large contracts were taken at fixed rates of profits, and therefore these profits, although sure ones, are necessarily not large ones, but at the same time they constitute a very safe and satisfactory feature of the Company's business, a feature which we hope to see extended during the course of the current year. Among the important orders in hand is one for the lighting of the city of Pretoria, which is the capital of the Transvaal, and in connection with this order, Mr. J. F. Albright, my co-managing Director, has recently visited South Africa, and will himself explain to you that there is every probability of our having there laid the foundation of a large business. With regard to other contracts, negotiations are in progress for very important central stations on the Continent, any one or more of which may be decided very shortly, and will result in a large increase of business. At the same time negotiations are also on foot for central stations for several important cities and towns in England and Scotland; it is, perhaps, not advisable to mention the names of these places at the present moment, but we think we stand a very fair chance of securing a considerable percentage of them, and if these are taken on the same basis as those already referred to of a fixed percentage of profits upon the actual outlay, this will secure, as I have already said, a safe and fairly remunerative profit for the shareholders. A firm like ours, which has always occupied a very leading place among the electric lighting manufacturers of the world, has necessarily to keep abreast of all the possible modern improvements; in fact, we have ourselves to be introducers of such improvements. During the past year, I am glad to tell you, we have worked hard at the subject of electric railways, and have succeeded in carrying out for the Southend Local Board an exceedingly successful example of the modern electric railway which has received the highest enconiums from everyone connected with it, the consulting engineer (Dr. John Hopkinson, F.R.S.,) to the Local Board himself stating he never passed the final certificates of any contract with so much pleasure and leaving so little to be desired. Another cognate branch of the business which we have developed during the year, at no small expense, has been the underground haulage for mines. We have carried out two very large sets of haulage with complete success, the last and most improved one having been successfully started last Friday. The results of these, however, do not show in the accounts that are now under consideration, but come into those of the current year. We are told by those who are the largest buyers of this class of machinery, viz., the colliery owners, that the success we have obtained is such that their orders alone are likely to nearly fill our order sheets. I may mention in connection with this that a very great deal of the credit of the success of this haulage plant is due to the exertions of our South Wales agent, Mr. Howell. You will observe in the report that we have expended a very considerable sum on capital account, partly in increasing our buildings at Chelmsford and fitting them up with the proper machinery and tools, but partly in fitting up our leasehold works which we have opened in London at Lillie-road. These works have been so far of great assistance to us, and enabled us to increase our output in a manner which we should be unable to do if we had not had them. Coming back to the statement of accounts, I would refer to the question of debentures. At our last meeting I informed you that we had decided to issue our second £25,000 out of the total of £50,000 of debentures, and we then offered them to our shareholders. The response was not quite so satisfactory as we expected. At the date of the report March 31st, only £31,050 had been subscribed—viz., a little over £6,000 since the meeting last year. At the present moment there are nearly £15,000 of these debentures remaining to be placed. The Directors have not in any way pushed the issue of these debentures by advertisement or otherwise; but it is really necessary that the Company should have this further additional capital, and the Directors will be glad if any of the shareholders will send in their applications so as to close the list by subscribing for the balance. The debentures, as you are aware, are amply secured, and as the total annual interest on the issue is only £2,500, and the net profits of the Company are now over £13,000, there can be little doubt that they will receive their money regularly in the future, as they have in the past. As exemplifying the advantage to the Company of having plenty of working capital at command, I may mention that last year the Directors were, enabled by careful management and prompt payment of accounts to their creditors, to secure for the Company an additional profit by extra cash discounts of a sum in excess of the total amount required for the year's interest for the whole of the debentures then issued. With regard to the distribution of the net profits, you will see that the Directors propose, after setting aside what they consider a sufficient provision for bad debts, to declare a dividend at the rate of 3s. 6d. per share, equivalent to 7 per cent. on the preference shares, and 5s. 6d. per share, making, with the previous interim dividend, a total of 8 per cent. per annum on the ordinary shares. I may say that the good

Digitized by Google

feeling, which I stated in my speech last year as existing between ourselves and our staff of workpeople, still continues to exist, and I have, on behalf of myself and the other Directors, to thank the staff for the satisfactory way in which they have worked during the past year, and I have to thank the works managers for the immense pains and trouble they have taken in promoting the working of the men's sick, recreation, and other clubs, and for the very cordial feeling which, in consequence exists between all the *employés* of the Company and the staff. I shall have pleasure in answering any questions of any of the shareholders present on any matters arising out of the report, and I will now conclude by moving the resolution mentioned, viz., that the report and statement of accounts be received and adopted. Resolutions will be proposed in regard to the appointment of new Directors, and I shall have pleasure later in referring to that subject. Mr. Albright, who has made a long business tour on behalf of the Company, only returned home two days ago, and he will be happy to give you some statement of his impressions and hopes of business resulting from his journey.

Mr. C. F. TUFNELL seconded the motion, which was carried unanimously.

The CHAIRMAN next moved :—

"*That a dividend at the rate of 7 per cent. per annum be declared and paid upon the preference shares of the Company.*"

Mr. J. F. ALBRIGHT seconded the resolution, which was agreed to *nem con.*

The CHAIRMAN moved, and Mr. PAYNE seconded, the next resolution as follows :—

"*That a dividend at the rate of 8% per annum be declared, and paid, upon the ordinary shares of the Company.*"

The motion having been carried unanimously,

The CHAIRMAN said that since the last meeting they had lost, he regretted to say, a very valuable Director, in the person of Sir Charles Grant. The Directors had appointed in his place, Mr. H. H. J. W. Drummond who, having been a considerable time on the Board, had been of great assistance to his colleagues. They had also secured the services of, another extremely valuable Director, Viscount Emlyn. He considered that the acquisition of these two gentlemen as members of the Board would give increased strength to the Company, and greatly increase the influence in the West of England. He had. therefore, much pleasure in moving :

"*That, in accordance with the 73rd clause of the Articles of Association the appointment of Mr. H. H. J. W. Drummond and Viscount Emlyn to be Directors of this Company is hereby approved and confirmed.*"

Mr. G. S. ALBRIGHT seconded the motion, which was carried unanimously.

The CHAIRMAN proposed, and Mr. PAYNE seconded, the following resolution :—

"*That Mr. Bernard Gibson be, and he is hereby, re-elected a Director of this Company.*"

The motion having been agreed to,

Mr. J. F. ALBRIGHT, in giving a brief description of his recent travels round the world in the interests of the Company, said that, the first place he visited was Canada, where he met the agents whom the Company had recently appointed there, and he had every reason to be satisfied with the agents they had selected. He believed that since his visit the orders that had been sent from Canada had been considerable. He visited the United States also, but, as they were aware, owing to the extremely high tariffs, it was almost impossible to do business there. After that he went to Australia, and saw the Company established there, and his impression was that they were in a position of being better represented in Australia than any other European firm or company. The prospect of business there was considerable. At the same time, it could only be done by people who knew the country well, and, in that respect, he had every reason to be satisfied. Then he went to India, where he was for a short time, and arranged for the representation of the Company by an old established house in Calcutta which had done more electrical work than any other firm. From India he went to Mauritius, where he found that all the work had been done, and no money to pay for it if there had been any to do. He then went on to Natal, proceeding at once to Pretoria, where he made final arrangements for lighting the City—a contract which was likely to be the means of establishing for them a very considerable and valuable business throughout South Africa. He had also made arrangements for their representation in other parts of the Transvaal, while he had had interviews with the Town Council of Durban and Cape Town, which might lead to profitable business. Having gone round the world he felt that he was now more competent to handle any matter in connection with their business in different parts of the globe.

Mr. G. S. ALBRIGHT proposed, and a SHAREHOLDER seconded, the next resolution, as follows :—

"*That Messrs. J. H. Duncan and Co. be, and are hereby, appointed auditors of the Company for the current year, at a remuneration of twenty-five guineas.*"

The motion having been carried,

A SHAREHOLDER proposed a vote of thanks to the Chairman and Directors.

The resolution was carried unanimously.

The CHAIRMAN briefly returned thanks, and expressed the hope that when he came before them next year it would be with a satisfactory result so far as the business of the Company was concerned.

The proceedings then terminated.

Manchester Edison-Swan Company (Limited).

The ninth ordinary general meeting of the proprietors of this Company was held on Wednesday, at the Victoria Hotel, Manchester. Mr. V. K. Armitage, Chairman, presided.

The CHAIRMAN, in moving the adoption of the report, which appears below, said that since their last meeting in February the Directors had tendered for one or two large installations, but seeing they would not get much out of the contracts, they had allowed the tenders to fall through, and just now they were not tendering for any large central lighting installation. The Directors had come to the conclusion that, at all events, some little of their money could be spent very well in another line of business. Mr. Williamson, their former Managing Director, had to go some 18 months ago to Australia for the benefit of his health. Some of the Directors of this Company formed a small company to establish Mr. Williamson in business in Sydney. Before he had been in Australia 12 months business increased so rapidly with him that the capital threatened to become but as a drop in the bucket compared with what was required. The Directors of the Edison Company who were not connected with the Williamson Company, and those who were, had had this subject thoroughly before them, and seeing that Mr. Williamson had got magnificent electric lighting orders on hand, and was likely to have others from Australian corporations, they resolved upon taking from the bank £2,500 which was lying idle, and purchasing with it shares in the Williamson Company. He (the Chairman) looked forward to the employment of a great deal of their money in Australia, but they might rely upon the Directors using extreme caution in all such investments. They would not send any money out there unless there was a chance of its being profitably employed. At the meeting of this Company, in February last, they were in hopes that the Corporation of Manchester were nearer than now seemed to be the case to a decision on their electric lighting order. They had obtained a Provisional Order, which rendered it necessary for them within a limited time to do a certain minimum amount of work. That time was running on, but they heard nothing clearly as to the carrying out of the Order, and he had begun to look less favourably than he once did upon their Company's chance of obtaining the Manchester Corporation's central lighting. In the meantime the Corporation had determined upon lighting with the electric light the Town Hall, which was outside the area of their compulsory order. The Company had tendered for the separate installation that was to be put into the Town Hall, and although a number of other firms had tendered for the same work, he believed they stood as well in as any of the others. He did not know whether the Corporation meant to run the installation themselves or to contract for it, but he sincerely believed the lighting of the Town Hall by electricity would be such an improvement upon the present illumination of the building that the Corporation would be encouraged to go on extending the electric light in future.

Mr. I. C. WATERHOUSE seconded the adoption of the report.

Mr. CHAS. AGNEW and Mr. BECHER took exception to the Company's money being invested in the Williamson Company, but the CHAIRMAN replied that the Directors had every reason to be convinced of the soundness of the investment, and the report was then passed.

Mr. F. B. ROSS was elected a Director, and the Directors' appointment of Mr. Fawcus as Managing Director was confirmed. The Directors' remuneration was fixed at £150, and Messrs. Jones, Crewdson, and Co. having been re-elected auditors, the meeting closed with a vote of thanks to the Chairman and Directors for their services.

The following is the Directors' report adopted at the above meeting : —

The Directors beg to submit the accompanying balance-sheet for the year ended May 30, 1891. The net profit, including last year's balance, amounts to £2,292. 10s., which it is proposed to appropriate as foliows : —

To payment of dividend at 5 per cent. per annum.	£1,000	0	0
To payment on account of 5 per cent. Cumulative preferential dividend on the "A" shares at the rate of 1¼ per cent. on £40,000 (the original capital of the Company), for the year ended May 30, 1883	500	0	0
Balance to be carried forward	792	10	0
	£2,292	10	0

If the above be approved, the dividend warrants will be issued on August 1, 1891.

Since the last general meeting the Directors have had to deplore the loss, by death, of their esteemed colleague, Mr. Edward Cross. The Directors have filled this vacancy on the Board by the election of Mr. Frederick B. Ross as a Director of the Company; Mr. W. P. James Fawcus, the Company's Manager, has been elected to fill the vacancy on the Board caused by the resignation, through ill-health, of Mr. J. R. Williamson, and the shareholders are asked to confirm his appointment as Director. Mr. Frederick B. Ross retires in accordance with the Company's Articles of Association : he is, however, eligible, and offers himself for re-election.

Anglo-American Telegraph Company (Limited).

The following is the report of the Directors of this Company, to be presented at the ordinary general half-yearly meeting of the proprietors, to be held at Winchester House, Old Broad-street, E.C., to-day (Friday), at 2 p.m. :—

The total receipts from the 1st January to the 30th June, 1891, including the estimated balance of £844. 7s. 3d. brought forward from the last account, are estimated at £139,184. 16s. 3d. This amount, however, is subject to rovision, as the lawsuit between this Company and the Paris and New York Telegraph Company is still pending. The traffic receipts

Digitized by Google

show a decrease of £8,432 as compared with the orresponding period of last year, caused in a large measure by depression of trade.

The total expenses of the half-year, including the repair of cables, &c., as shown by the revenue account, amount to £54,657. 11s. 5d.

One quarterly interim dividend of 12s. per cent. on the ordinary stock, and of £1. 4s. per cent. on the preferred stock, was paid May 1, 1891, absorbing £42,000, and a second quarterly dividend at the same rates will be paid on August 1, 1891, leaving a balance of £527. 4s. 10d. to be carried forward to the next account.

The Company's repairing s.s. "Minia" has been engaged during the past half-year in the repair of the 1873 cable, off the coast of Ireland, and of one of the cables connecting Hearts Content with Placentia, Newfoundland. The vessel was chartered to the Direct United States Cable Company on March 25th for executing repairs, the remuneration for which will be found in the revenue account.

The Company's cables and land lines are in good working order, with the exception of the North Placentia Cable, which was broken on the 4th June.

New offices have been opened in Mark-lane and Tooley-street, London, and at Bradford, Dundee, Edinburgh, Leith, Newcastle-on-Tyne, Havre and Montreal. Direct communication has also been established between the Company's offices at Brest and Havre, and the Government office at the Paris Bourse, by means of a special wire conceded to the Company by the French Government.

Progress has been made, since the last report, in the lawsuit so long pending between the Anglo Company and the Paris and New York Telegraph Company. The appeal of the Anglo Company was argued before the Council of State on May 1st, and the decision of the Council of Prefecture was reversed in this Company's favour. The case will now be heard by the Court of Appeal on the question of damages, and it is expected that judgment will be pronounced soon after the termination of the Long Vacation.

United River Plate Telephone Company (Limited).

The following report is issued by the Directors of this Company, and will be presented to the shareholders at the fifth ordinary general meeting at Winchester House, E.C., on Friday, August 7th, at 12 o'clock:—

The result of the Company's operations for the year ending March 31st last shows, after paying all working expenses abroad, debenture interest, London, and other charges, a profit of £38,480. 14s. 4d., from which is to be deducted the sum of £36,049. 0s. 8d. for loss on exchange, leaving a net profit of £2,431. 13s. 8d., to be increased by the balance of £2,373. 16s. 6d. brought forward from the previous year, to £4,805. 10s. 2d. Out of this, the Directors recommend that £768. 7s. 8d. be applied in writing off one-half of the taxes suspense account, and £2,000 be written off for bad and doubtful debts in the River Plate, and that the balance of £2,037. 2s. 6d. be carried forward to the credit of profit and loss account for the current year. As shown in the balance-sheet accompanying the report, the capital expenditure during the year amounted to £3,096. 10s. 10d., as against £12,772. 8s. in the previous twelve months.

It will be observed from the profit and loss account, that notwithstanding the revolution in July, 1890, and the continued crisis in the River Plate, which has practically stopped the Company's sales' business, the gross receipts for the year are £106,259. 19s. 8d., as compared with £108,612. 2s. 7d. in the year before. The loss on exchange, £36,049. 0s. 8d., represents nearly 12½ per cent. on the Company's paid up share capital.

The working expenses in the River Plate amount to £56,941, 1s. 9d., against £63,497. 15s. 5d. during the previous year, and the London expenses to £2,732. 14s. 9d., against £3,257. 15s. 6d. Since the close of the year the London expenses have been still further reduced by about one-third.

The Directors greatly regret the loss by death of their late colleague, Mr. John Coghlan, in September last, and that Lord Thurlow, owing to pressure of other engagements, resigned the Chairmanship in April; in the place of Mr. Coghlan, the Directors elected Mr. Unwin, on his retirement from the secretaryship in March last.

Under the Articles of Association, Mr. John Irving Courtenay and Mr. John Owen Unwin retire by rotation, and, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Brothers and Co., also retire, and offer themselves for re election.

NEW COMPANIES, STATUTORY RETURNS, &c.

GEORGE W. PRIDMORE AND COMPANY (LIMITED).—This Company was registered on July 21, 1891, with a capital of £1,000 in £5 shares, by H. H. Richardson, 2, Broad-street-buildings, E.C. The objects are: To adopt and carry into effect an agreement, dated May 18, 1891, made between G. W. Pridmore, of 110, Holyhead-road, Handsworth, of the one part, and W. Everden, of Suffolk House, Cannon-street, E.C. (as trustee for the Company) of the other part, and to carry on business as manufacturers of all kinds of lamps, and of apparatus connected with the manufacture, purification, consumption, supply and distribution of gas and electricity. Office: Suffolk House, Laurence Pountney-hill, E.C.

HOME TELEPHONE COMPANY (LIMITED).—This Company was registered on July 27, 1891, with a capital of £500, in £5 shares, by H. P. Spottiswoode, 32, Craven-street, Charing-cross. The objects are: To acquire any Letters Patent, rights, or privileges for the use, sale, or manufacture of any telephone, telegraph, electric light, electric power apparatus, or any other invention, instrument, or apparatus connected with the utilisation of electricity; to contract for the carrying on of any telegraphic, telephonic, electric light or power, or any other business; and to establish and conduct any system of telephonic or telegraphic communications, or for the transmission, storage, utilisation, or application of electricity. The regulations of Table A (First Schedule, Companies Act, 1862) mainly apply. Office: 85, Queen Victoria street, E.C.

MORECAMBE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—This Company was registered on July 27, 1891, with a capital of £15,000, divided into 14,950 ordinary and 50 founders' shares of £1 each, by J. Tilly, solicitor, Lancaster. The objects are: To acquire the rights of T. R. Andrews and T. Preece (who are the undertakers of the Morecambe Electric Light and Power Order, 1890) of and in the undertaking authorised by that Order. To become the undertakers of that Order, by adopting and carrying into effect an agreement, dated June 27, 1891, made between the above T. R. Andrews and T. Preece of the one part, and J. Jowett (for and on behalf of the Company) of the other part, and to carry on the business of electricians, mechanical and electrical engineers, manufacturers of and workers and dealers in electricity, electric motive power, and electric light for all public and private purposes. Registered without Articles of Association. Office: 18, The Crescent, Morecambe.

SOUTH BEACH LAND AND BUILDING CORPORATION (LIMITED).—This Company was registered on July 25th, with a capital of £5,000, in £5 shares, by Jordan and Sons, 120, Chancery-lane, W.C. The objects are: To acquire and develop, build on, or otherwise turn to account land at Pwllheli, in the county of Carnarvon, to construct, maintain, improve, work, and control waterworks, gasworks, roads, tramways, electric power, heat, and light, supply works, telephone works, and other conveniences of public utility, and to carry on the businesses of builders, decorators, merchants, electrical engineers, &c. Registered without Articles of Asociation. Office: Gwyddonfa, Pwllheli, North Wales.

TAYLER SMITH ELECTRIC COMPANY (LIMITED).—This Company was registered on the 21st inst., with a capital of £6,000, divided into 300 Six per Cent. Preference and 300 ordinary shares of £10 each, by Cave and Co., solicitors to the Company, 4, Fenchurch-street, E.C. The objects are: To purchase or otherwise acquire the business and goodwill of Mr. Thomas Tayler Smith, electrical engineer, of 4, Circus-place, London, E.C., and to carry on the business of electrical engineers, contractors for electric lighting, and other works connected with the use of electricity, and manufacturers of and dealers in electric plant, fittings, and apparatus. The first subscriber is the Earl of Shrewsbury and Talbot, Ingestre, Stafford, who takes one preference share. The business of the Company is to be carried on by managers, the first being T. T. Smith, of the above address, and Keppel Stephenson, of 34, Beaufort-gardens, S.W. Office: 53, South Molton-street, Oxford-street, W.

AUTOMATIC ELECTRIC RAILWAY SIGNAL COMPANY (LIMITED).—A meeting of this Company was held on July 22, 1891, for the purpose of having an account laid before them, showing the manner in which the winding up of the Company had been conducted and the property disposed of, and the same was done accordingly. Offices: 11, Rumford place, Liverpool.

BLOCKLEY ELECTRIC LIGHTING AND MANUFACTURING COMPANY (LIMITED).—The third annual return, made up to June 13th, was filed on June 20, 1891. The Company, which was registered on December 16, 1887, has a capital of £20,000, in £5 shares. 508 shares have been taken up, the full amount called upon each, and calls paid amounting to £2,540. Office: Blockley, Worcester.

CITY OF LONDON ELECTRIC LIGHTING (PIONEER) COMPANY (LIMITED).—The statutory return of this Company, made up to June 8, 1891, was filed on the 20th June. The Company, which was registered on the 5th February last, has a nominal capital of £100,000, in £50 shares; 1,000 shares have been taken up, upon each of which £25 has been called and paid. Offices: 1 and 2, Great Winchester-street, London, E.C.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—The first annual return of this Company, made up to July 1st, was filed on July 11, 1891. The Company, which was registered on May 20, 1890, has a capital of £200,000, divided into 39,900 ordinary and 100 founders' shares, of £5 each; 20,000 ordinary, and all the founders' shares have been taken up, and upon the ordinary shares £1 per share has been called and paid, while upon the founders' shares the full amount has been called and paid, the calls paid amounting to £20,500. Office: 1 and 2, Great Winchester-street, E.C.

HOUSE-TO-HOUSE ELECTRIC LIGHT SUPPLY COMPANY (LIMITED).—The annual return of this Company made up to July 3rd last, was filed on the 11th. The Company, which was registered on February 20, 1888, has a nominal capital of £350,000, divided into 100 founders', 57,900 ordinary, and 12,000 preference shares, each of £5 each. 100 founders', 8,322 ordinary, and 342 preference shares are taken up, upon each of which the full amount has been called. The calls paid amount to £38,278, considered as paid on 100 founders' and 1,000 ordinary shares, £5,500 and unpaid to £42. Office: 117, Bishopsgate-street Within, E.C.

SHROPSHIRE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The statutory return of this Company, made up to June 12, 1891, was filed on June 19th last. The Company, which was registered on January 30th last, has a nominal capital of £25,000, in £10 shares. 275 shares have been taken up, but upon these no calls have been made. The total allotment money paid amounts to £510, and unpaid to £40. Registered office, 9, The Square, Shrewsbury.

STAMFORD HILL, TOTTENHAM, AND EDMONTON ELECTRIC LIGHT AND POWER SUPPLY (LIMITED).—The following special resolution was

Digitized by Google

passed on June 3, 1891, and confirmed June 24, 1891:—"That the name of the Company be changed to the Putney and Hammersmith Electric Light and Power Supply (Limited)." The approval of the Board of Trade to the above change was granted on July 1st, and filed on July 6, 1891.

CITY NOTES, &c.

AKESTER ELECTRIC MOTOR COMPANY (LIMITED).—A meeting of the shareholders in this Company was held at the Cannon-street Hotel, on Wednesday last, but the proceedings were private.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The traffic receipts of this Company for the past week amounted to £686.

HEROLD TELEGRAPH COMPANY OF BERLIN.—At a general meeting of this Company it has been decided to increase the capital from 800,000 marks to 1,000,000 marks.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The Directors recommend a half-yearly dividend at the rate of 8 per cent. per annum.

NORTH METROPOLITAN TRAMWAYS COMPANY (LIMITED).—The Directors, in their report just issued, allude to their unsuccessful application to Parliament to amend Section 4 of the North Metropolitan Act, 1890, which gives power to the Local Authorities to give their consent for the use of electricity on the Company's lines on such terms and conditions as they might think fit. The arrangements entered into with the General Electric Power and Traction Company (Limited), however, for working the traffic on the Barking-road section are still in operation, and during the last half-year 37,767 miles have been run by electricity.

SANITAS COMPANY (LIMITED).—The Directors have declared an interim dividend at the rate of 10 per cent. per annum for the six months ended June 30th last, free of income-tax, and payable on or after September 1st next. The transfer books will be closed from August 25th to August 31st next.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The Stock Exchange Committee have ordered 5,324 additional shares, Nos. 92,048 to 97,371, of this Company to be quoted in the official list.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 690.—Vol. XXVII. FRIDAY, AUGUST 7, 1891. Price Fourpence.

NOTES.

At a special general meeting of the Institution of Electrical Engineers, which is not likely to be largely attended at so late a time of year as August 13th, the alteration of those Articles of Association which refer to the subscriptions and entrance fees will be discussed. As will be readily guessed, the alterations refer to an increase of the subscriptions; but they will only affect new members who are elected after the end of the present year. By members we include associates and students, but the Institution draws a peculiar distinction between its members proper and the other classes. Members only are invited to this meeting, although associates and students will be quite as much affected by the resolution which will be placed before it. The Institution of Civil Engineers includes as members both its associate members, its associates, and its students; but the two former classes are corporate members. The large body of associate members are entitled to all the privileges, and are not excluded from such meetings as the above, nor are they debarred from voting, or from acting as scrutineers for the ballots. The Civil Engineers hold out no inducements to the associate members to become full members by allowing the latter to control the affairs of the Institution, but make such full membership an honorary distinction.

A still more peculiar custom of the Institution of Electrical Engineers is to demand an additional entrance fee for transfer from one class to another. We do not complain so much about the fee, which is only, perhaps, a little annoying because it is so unusual, for we are fully alive to the fact that one of the chief difficulties with which the Institution has to contend is its small revenue; but why call these entrance fees? If a student does not actually enter the Institution on his election, as he does when he joins the Civil Engineers, he at least should be considered to do so when he becomes an associate. If more fees are wanted, let them be called transfer fees, for that is what they really are. We hope that there will be a rush of new members at the beginning of the next session, who will be anxious to get in before the fees are raised, and thus benefit the Institution by a material increase of numbers as well as an addition to its revenue. As it is possible that the resolution may be amended at the meeting next Thursday, we have not printed it in this issue, but hope to give it as it finally passes the meeting.

On Friday last the Barnet Local Board sealed a contract with the District Gas and Water Company for the public lighting, and so terminated the unfortunate and ill-advised attempt to light streets with glow lamps. The contractors have a distinct grievance against the Board, since the electric lighting was carried out on the understanding that assent would be given to their application for a Provisional Order. But there have been so many failures, and so many of the lamps have been below the proper candle-power, that much dissatisfaction has been caused, and, no doubt, some reasons could be put forward for the refusal to support the contractors' application for an Order. The special pleading which is sometimes used with no little ingenuity to show that lighting by glow lamps is, as a rule, as cheap as gas, cannot be applied to such a concern as the Barnet lighting. The arguments about health, cleanliness, and coolness do not apply, and we do not see how the glow lamp can compete with gas for street lighting, except under favourable conditions, and on a much more important scale than Barnet. It is far too good for such a purpose. The contractors seem to have made a final effort to run an arc lamp, but its behaviour was not satisfactory, and, on account of the breach of faith of the Board and other conditions imposed, they have not attempted to renew the contract. Contractors do not require such a warning as this to teach them that street lighting is the least profitable work that they can touch, and that glow lamps, even if properly put up, offer but little advantage for this purpose over gas, except the saving of a lamplighter.

The case of Crompton and Company *v.* Phillips raised, as Lord Justice Lindley observed in the Court of Appeal, an important question, not only to the parties but to all persons interested in electric lighting. A considerable quantity of wire was bought by the plaintiffs for out-door work in Chelmsford. It does not appear that any specification was given or guarantee asked for the actual insulation resistance, and it will be remembered that the Board of Trade rules for aerial conductors (*The Electrician*, August 29, 1890) do not require so many megohms per mile, but (§ 33) that "every high-pressure aerial conductor shall be continuously insulated with a durable and efficient material, to be approved by the Board of Trade, to a thickness of not less than one-tenth part of an inch, &c." The wire in question was described as C quality, which, as it stands, only implies that it ranks between B and D, and, therefore, while not as good as it might be, is better than some other quality which is still covered with vulcanised rubber. Whatever else quality C meant, said Lord Justice

Digitized by Google

KAY, it meant at least this—that the wire was insulated. The details of the experts' evidence were given in full in our issue of June 26th, and there it appeared that there were numerous cracks and open seams in the insulation, but in the opinion of two engineers C quality wire was suitable for house work for 100 volts. Fortunately, the jury were not asked to decide upon the kind of insulation suitable for out-door or for house work, and it is hardly likely that they would be led away to imagine that a wire which was not good enough to put up on poles was really intended, and was a proper article, to put into a house.

IT appears to us that, so long as it passes the Board of Trade, an overhead wire may have cracks at every five inches instead of every five yards, and be little the worse for them provided proper insulators are used; but we are sorry to learn that anything but a really first-rate quality of insulation should be thought "good enough" for house work. For overhead work, a fair insulation and a strong mechanical protection are needed, and the Board of Trade regulations say nothing about insulation except that which may be provided by good insulators on the posts. For indoor work, there is ample mechanical protection in the wood casing, and what is wanted is a first-class insulation which shall resist damp.

UNDER the not very appropriate title of London Day by Day, the *Daily Telegraph* inquired yesterday why electric traction is a success in America but a comparative failure in England; and puts forward the statement that experts say it is due to the conditions imposed by Parliament that electrical engineering generally has advanced in this country at such a snail's pace. We do not know who these experts may be, and cannot recall any conditions, other than the Board of Trade regulations for aerial conductors, which can be said to hamper electric traction. The reason simply appears to lie in the fact that nearly all the traction in America is done with a trolley wire, and this would not be tolerated in our streets. It is precisely the same with electric lighting. We have heard for years past, that Americans have been ahead of us in electric lighting; but it was of a quality, to put it mildly, unsuitable for this country. Electric lighting is progressing fast enough now, as fast as anyone could wish, and it is all the better for having been slow. We are confident that electric traction will come on just as surely, and with as many advantages due to maturity. The only obstacle of this kind encountered by electric traction have been the conditions imposed by Local Authorities. The Lineff closed conduit system, which was at one time very promising, appears to have suffered severely from this form of opposition.

THE sections on the influence joints in Prof. EWING'S articles on magnetism, which will be found in another column, treat of a matter which is of considerable interest to dynamo makers. The question was first raised in a Paper by Prof. EWING and Mr. LOW, at the British Association, at Manchester, in 1887 (*The Electrician*, Vol. XIX., p. 439). It was argued, during the discussion which followed that Paper, that little or no advantage could be obtained by screwing the limbs of magnets more tightly to the yoke, for the pressures required to diminish the magnetic resistance of the joint to any useful extent were far greater than could be attained in practice. Prof. EWING'S researches show very clearly the exact effect which may be expected, and the equivalent air-gap is easily calculated, and is more accurate than the addition of eight inches to the length of the bar, which was suggested in the discussion to which we have referred. It seems probable that the curvature of the line in Fig. 134, page 380, of the present issue is simply due to errors of observation, and this makes the correction a very simple one. The continuation of these articles deals with rough joints, and the effect of successive joints. A rough joint offers only slightly more resistance than a well surfaced joint, but the resistance of the former is reduced comparatively little by pressure. Engineers will, therefore, merely waste money in scraping up their joints, and may easily calculate to what extent it is worth while to avoid them by using expensive forgings.

WE present to our readers this week three articles on the poly-phase alternate current system. We have held over the abstract of VON DOLIVO-DOBROWOLSKY'S Paper for some weeks until we could give an account of a practical form of dynamo used, and this will be found in the description of the 300 H.P. Oerlikon dynamo devised by Mr. C. E. L. BROWN. In another column will be found a very useful *resumé* of the subject in the form of a translation of a Paper by M. HOSPITALIER.

Telephone Trunk Wires.—A third telephone wire is to be established between Brussels and Amiens.

The New North Sea Cable.—The laying of the new cable between Denmark and France, that is from Fanö to Calais, was successfully completed last week.

Prague.—The electric railway to the Baumgarten was opened on July 18th. The hours of running are from 6 a.m. to 9 p.m. in the summer, and from 7 a.m. to 8 p.m. in the winter.

Lynton.—The Local Board has received notice of intended application for a Provisional Order from the Devon Electric Lighting Company.

A Good Rule for Street Lighting.—According to a gas contemporary, the only rule for street lighting that operates with local authorities is to pay for gas as little as they can, and for electricity as much as they dare.

Telephonic Transmission.—On Sunday last the whole of the service at Christ Church, Birmingham, was transmitted to Kidderminster to the house of Mr. Johnston, the local manager of the National Telephone Company.

West Ham.—At the last meeting of the Town Council it was decided to employ Professor H. Robinson to inspect the district, and to advise as to the best method and approximate cost of the installation of an electric system.

Owens College, Manchester.—The Session of this College begins on the 6th October. A Special Course has been arranged on the Technical Applications of Electricity. For further particulars, see our advertisement columns.

Oxford.—Some time ago a Provisional Order was granted to the Electric Installation and Maintenance Company. Plans have now been presented to the General Purposes Committee of the Corporation. The low tension system, with sub-stations, will be employed.

Frankfort Exhibition.—Numerous favourable replies have been received in answer to the recent circular of the Electrical Trades Section suggesting that a visit should be paid to the Frankfort Exhibition in a party. There is, therefore, little doubt that the visit will take place.

Digitized by Google

The Telegraph Business at the House of Commons.—The postal business transacted at the House of Commons this Session has been exceptionally heavy, especially in the telegraph department. The number of messages despatched was 51,637; and no fewer than 17,258 were received.

"Electricity."—The latest addition to the formidable host of American electrical publications is a weekly illustrated journal entitled *Electricity*, published at Chicago. *Electricity* is to be "popular and practical as well as merely technical and theoretical," and in the first number there is certainly a judicious blending of everything electrical.

Copper.—The July statistics of the copper trade, which have been issued by Messrs. Henry R. Merton and Co., show that although the new supplies have been decidedly below the recent average the deliveries have been still smaller. They have, indeed, been absolutely less than in any month since March, 1889, and the visible stocks which have, up to the present, shown a steady diminution, have risen 1,400 tons during July.

The Post Office and the Telephones.—The Wolverhampton Chamber of Commerce lately received a communication from the Postmaster-General, stating that the Government did not contemplate immediately taking over the undertakings of the telephone companies; but were prepared to establish telephone exchanges in centres where required, and that the whole question of telephonic communication was still under consideration by the Department.

The Grassot Electrolytic Meter.—The electrolytic electricity meter devised by M. E. Grassot, has certainly the merit of originality. It consists of a silver wire 5mm. in diameter, placed in a glass tube, and dipping for a distance of about 3mm. into a solution of nitrate of silver. The silver wire is an anode to a cathode of zinc, and as it loses weight it is made to descend and pull round a drum actuating a train of clockwheels and indicating dials.

Gas and Electricity in France.—From recent accounts it appears that the consumption of gas in Paris in 1890 exceeded that in 1880 by 26·2 per cent. While the number of consumers increased 56·8 per cent., the amount per consumer diminished 19·5 per cent. The same account states that in *three* years the number of arc and glow-lamps has increased 140 and 170 per cent. respectively. The consumption of petroleum in France has increased 47 per cent. in those ten years, while that of gas, in the whole of France, has grown 62 per cent.

City and South London Electric Railway.—In view of the extension of the line from Stockwell to Clapham, for which the Company already have Parliamentary powers, they are making arrangements for a considerable extension of the generating plant at the Stockwell Station. They have placed the order with Messrs. Mather and Platt, of Manchester, for a fourth generating dynamo, similar to the three at present working the line. The dynamo is to be of the "Edison-Hopkinson" type, and to have an output of about 400 H.P. The Company have also ordered a fourth engine from Messrs. John Fowler and Company, similar to the three existing engines, and have made arrangements for an increase of their rolling stock.

The Société d'Encouragement.—The Société d'Encouragement has offered a prize, for 1893, of 3,000fr., which will be awarded to anyone discovering a substance partially, if not wholly, taking the place of gutta-percha, or to anyone who has made the most deserving contribution to the knowledge of the planting, acclimatisation, or improvements in the culture of the gutta tree. Another prize of 2,000fr. is for the best apparatus or industrial method by means of which the insulation of the different parts of an electrical plant can be measured while the full current is on. Further particulars can be obtained from the secretary of the Society, 44, Rue de Rennes, Paris, before December 1, 1892. Communications should, if possible, be in French.

The International Electric Company of Vienna.—The following particulars are given concerning this Company's central station in Vienna, which has now been running since November last. The Ganz system is employed. At the central station are six Steinmüller tubular boilers working at 150lb. pressure, and four compound engines, three of 600 H.P., and the fourth of 300. The former is coupled direct to 400 unit Zipernowsky alternators, making 125 revolutions, and the latter to a 200-unit machine, running at 170 revolutions. The excitation is effected by three 35-unit machines coupled direct to a Westinghouse engine. Three Berthoud-Borel cables capable of supplying 23,000 16 c.p. lamps start from the distributing board. The total length of conduits laid is over 20 miles. Transformers for 2, 4, and 8 units are employed, and Blathy meters are in use.

The French West Indian Cables.—Mr. W. Sharpey Seaton informs us that, on the 31st ultimo, his engineer-in-chief, Mr. Theophilus Smith, telegraphed him that the Cayenne-Viseo cable was successfully laid. This completes the system of about 2,500 nautical miles which has been laid for the Société Française des Télégraphes Sous-Marins. The first expedition was directed by Mr. Seaton in person, the second was entrusted by him to Mr. Theophilus Smith, who has been assisted by Messrs. Stallibrass, Page, Schischkar, Hall, Roussel, Fisher, Bevan, Sullivan, Spain, and other engineers and electricians, as well as by Captain Stonehouse and Mr. Dunn, the chief of the engine room. The first official message despatched was that of the Governor of Cayenne to the President of the French Republic, conveying the best wishes of the Colony for M. Carnot.

Frequency of Thunderstorms.—A German periodical gives statistics concerning the frequency of thunderstorms in various regions of the world. Java has thunderstorms on the average 97 days in the year; Sumatra, 86; Hindostan, 56; Borneo, 54; the Gold Coast, 52; Rio de Janeiro, 51; Italy, 38; West Indies, 36; South Guinea, 32; Buenos Ayres, Canada, and Austria, 23; Baden, Wurtemburg, and Hungary, 22; Silesia, Bavaria, and Belgium, 21; Holland, 18; Saxony and Brandenburg, 17; France, Austria, and South Russia, 16; Spain and Portugal, 15; Sweden and Finland, 8; England and the high Swiss mountains, 7; Norway, 4; Cairo, 3. In East Turkestan, as well as in the extreme north, there are almost no thunderstorms. The northern limits of the thunderstorms are Cape Ogle, northern part of North America, Iceland, Novaja, Semelja, and the coast of the Siberian ice sea.

The Electric Lighting Business in Paris.—Judging by the following remarks of the *Bulletin International de l'Electricité*, the electric supply business, in spite of the high price of gas, is not giving entire satisfaction to those engaged in it. "There are rumours going about with regard to the uniting under one management of several of the Paris electric lighting concessions. The individuals who are so well acquainted with the projects of the Rothschilds ought to know that they have enough to do in working the district they possess, without taking over ancient concessions of doubtful value, or promoting new concessions. There are, indeed, some who do not think the business sufficiently spoilt, and who talk of supplying the hecto-watt hour taken at the station door for 2·5 centimes. We fail to see what would be gained by a combination of the kind, either from the financiers' or the contractors' point of view. Both are wealthy, but not wealthy enough to stand the consequences of such an absurd enterprise."

Some Researches in Magnetism.—In a recent number of *Wiedemann's Annalen* Karl Frome states that some earlier experiments led him to the conclusion that the maximum value of the permanent (residual) magnetic moment P.M. attained by a body previously unmagnetised through the repeated application of the same magnetising force P, could neither be raised nor changed by the application of a force equal to or smaller than P, and acting in the same direction. Later tests, however, had convinced him that this was incorrect. The magnetised bodies consisted of bundles of iron wire, pieces of wrought iron, and mild steel. One experiment was as follows:—A piece of iron was magnetised to a constant value of P.M. by means of repeated applications of a current of one ampere and then subjected to the influence of a smaller current. In all cases the application of the weaker force due to the smaller current effected at first an increase in P.M. until it reached a maximum, and then a decrease through the original value to a negative maximum, and finally an increase again. The communication further deals with the influence the shape of an

Digitized by Google

iron core has upon the effect of small forces. Such an influence appears to exist, though its nature is not very clear.

The Taunton Exhibition.—The West of England and South Wales Electrical Exhibition opened, on Saturday last, at Taunton. It is held in the Central Station of the Taunton Electric Light Company; the yard and all available space having been covered in for the purpose. The opening ceremony took place at 3:30 p.m., when Field-Marshal Sir Lintorn Simmons, in a short speech, declared the Exhibition open. The Exhibition is not in a finished state at present. Several cases of goods have yet to be unpacked, and the stalls are not for the most part properly arranged. There are about 40 exhibitors, amongst whom are Messrs. Rashleigh Phipps and Dawson, Messrs. King, Mendham and Co., Messrs. Davis and Sons (Bath), the Blackman Ventilating Company, MM. Richard Frères, Mr. F. M. Newton (Taunton), the Keys' Electric Company, the Bath and Exeter Electric Light Companies, Messrs. Appleton, Burbey, and Williamson, the Babcock and Wilcox Company, and Messrs. Laurence, Scott and Co. One of the best and most interesting exhibits is that of Mr. F. M. Newton, who shows a "Taunton" dynamo driven by a 5 H.P. Priestman oil engine, charging a set of 34 accumulators; patent switch board hinged to a fixed ornamental post, so that wires, &c., may be examined at back, patent brush holders, &c. There is a small electric launch moored near the bridge, which will make short trips on the river. The electric "bus" has not yet commenced to run. The attendance is fairly good.

Thunderstorms.—During the past few days severe rainstorms, accompanied by thunder and lightning, have occurred all over Europe and the United Kingdom. At the beginning of the week in the course of 24 hours some half-dozen thunderstorms, of more than usual severity, occurred along the Norfolk and Suffolk coast. At Lowestoft a flash struck a house near the hospital. It cut the chimney in two, and, entering the lower room, destroyed the chimney-piece, split the fire-grate, and carried a portion of it into the centre of the room. At Gorleston the National Lifeboat house was damaged by lightning. The roof was stripped of the slates, and the glass in the windows was shattered. At Croydon a labourer and his wife were struck by lightning. The former was killed on the spot, and the woman has since died from shock to the system. On Tuesday many parts of the country were again visited by thunderstorms. Several houses were damaged and a large number of cattle killed. In Germany, during a thunderstorm on Friday last, a detachment of the First Regiment of Guards, while engaged in musketry practice at Potsdam, was struck by lightning, and four of the men were deprived of consciousness. On Monday the town of Rathenow was visited by a thunderstorm, during which the large garrison stores were struck by lightning and set on fire. The flames spread very quickly, and the entire magazine was soon reduced to ruin. On the lowest estimate there is a loss of 1,500,000 marks.

The Wurts-Winsor Lightning Guard.—The Wurts-Winsor lightning guard, says the *Electrical World* of New York, has a cylindrical air chamber of brass, each end of which is covered with a marble plate. Two discharge points on opposite sides of the air chamber, consisting of brass tubes tipped with carbon, are attached to lever arms, so as to swing freely through openings in the marble plates. Within the air chamber is a fixed carbon ball, and the two discharge points approach this ball to within one-sixteenth of an inch. The ball is earthed and the lever arms connected to the respective poles of the generator. If a lightning discharge comes in from the line a discharge takes place from the two discharge points to the carbon ball, and from thence to earth. The dynamo current then follows, causing a short circuit, and the heat produced by the arc expands the air in the chamber and drives the two discharge points out, extinguishing the arcs and rupturing the short circuit. The discharge points then swing back, and the apparatus is ready for another discharge. In testing one of these instruments the binding posts were connected to the poles of a 1,000-volt alternator, and the two air spaces were bridged over with a small strip of tinfoil. Then, by the throw of a switch, the generator was short-circuited through the lightning guard, the tinfoil was fused, the air expanded, the discharge points were forced out of the air chamber, the arcs were blown out, and the points returned to their normal positions. After several hundred such discharges the instrument is said to have shown no deterioration.

Steam-Boiler Economy.—The general subject of steam engines and boilers was recently discussed by Mr. John M'Laren, in a communication to the Federated Institute of Mining Engineers. The author remarked that Cornish or Lancashire boilers, with a heating surface of about 14 square feet per horse-power, were displacing the cruder patterns. Tubular or water-tube boilers, largely adopted on the Continent and in America, were coming into limited use in this country. Their economy, however, he thought, was doubtful; they were given to priming, and a great disparity of results has been noted in reported tests. Mr. M'Laren thinks the locomotive type of boiler unquestionably the best and most economical steam generator in practical use. These boilers require no expensive setting, and are easily looked after. They can be stayed so as to be absolutely safe at pressures up to any practical limit; they occupy the least space of any boilers in proportion to their power; and they give an extremely high evaporative duty. There is an unreasonable prejudice against these boilers in the minds of some steam users, owing to their supposed greater wear and tear, though in practice they will be found, in the end, to cost no more for repairs than Cornish or Lancashire boilers doing equal duty. The evaporative efficiency of the different types of boilers may be stated approximately as follows:—Egg-ended boilers, 4·6lb. of water per pound of fuel; Lancashire boilers, 8lb. of water per pound; tubular boilers, 7lb. to 10lb. of water per pound; locomotive type boilers, 11lb. of water per pound—all from and at 212° Fahr. According to Mr. M'Laren, the highest economy of both boiler and engine obtained in a properly authenticated experiment is 1 I.H.P. for a consumption of 1·35lb. of coal per hour, which is about 11·75 per cent. of the theoretical capability of the fuel used.

The Chicago Exhibition.—The following amusing paragraph from the *Spectator* doubtless describes the feelings of many of our readers who are endeavouring to develop the proper amount of enthusiasm about the forthcoming "World's Fair" at Chicago: "Nothing, as a rule, can be duller to think of, or to write about, than International Exhibitions. They may have their uses, but these are not apparent, and the thought of a 'World's Fair' is apt to call up sickening recollections of the blank misgivings suffered by creatures who have wandered about in worlds unrealised, and beheld, with a sentiment akin to horror, a vast welter of 'miscellaneous exhibits.' Hope springs eternal in the human breast, and people imagine that, somehow or other, their second exhibition will not be like their first, else the promoters of such infernos would long ago have been regarded and treated as *hostes humani generis*. We do not believe that there exists a human being who, if forced to speak the truth, the whole truth, and nothing but the truth, would fail to admit that the prevailing sensation experienced during the 'doing' of any particular exhibition was one of mental and physical exhaustion of the most acute kind. The trudging through endless hot and draughty sheds, mocked by the name of 'pavilions,' and lined with huge glass cases, the miserable longing for food, never satisfied till too late, and the horrible sense of intellectual repletion which gradually grows on the exhibition goer, are remembered by most people like a hideous nightmare. Yet, somehow or other, many of them fancy that it will be different next time, that they will manage better, and that at last they will contrive not merely to see, but to enjoy, the wonders of the show. Hence it happens that exhibitions are tolerated, in spite of the fact that no sane person was ever known to obtain enjoyment thereby. Though we cannot profess to feel any enthusiasm at the thought of the Chicago Exhibition, we have no hesitation in adopting the formula used by the hero of Illinois when he desired to express a general sympathy with things which he personally disliked. On such occasions Mr. Lincoln was wont to observe, that for 'those who like that sort of thing, that's just what they like.' This is exactly our feeling towards the Chicago Exhibition. As long as we can keep away ourselves, we shall find no difficulty in declaring 'that those who like that sort of thing' will find the Exhibition 'just what they like.'"

MAGNETISM IN IRON AND OTHER METALS.*—XLVI.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 325.*)

§161. **Bar and Yoke.**—In speaking of applications of the idea of the magnetic circuit, we may revert briefly to the arrangement of bar and yoke, first used by Hopkinson in experiments on susceptibility, and described above in §§ 58-59, Figs. 26 and 27. The function of the yoke is to make the bar form part of a nearly perfect magnetic circuit, of which the resistance of the bar itself is nearly the whole resistance. Let l_1 be the effective length of the bar, which is somewhat greater than its clear length within the yoke (since there is a gradual spreading out of the lines of induction when the bar penetrates the yoke), and let s_1 be the cross section of the bar. Let l_2 be the length of the return path of the lines through the yoke, and s_2 the cross section of the return path, which is the sum of the cross sections of the two sides of the yoke. Let N, as usual, be the number of turns of the magnetising coil, which is wound on the bar. Then, by the principle of the magnetic circuit,

$$4\pi C N = \text{Flux} \times \left(\frac{l_1}{\mu_1 s_1} + \frac{l_2}{\mu_2 s_2}\right),$$

$$= \mathsf{B}_1 s_1 \left(\frac{l_1}{\mu_1 s_1} + \frac{l_2}{\mu_2 s_2}\right),$$

where B_1 is the magnetic induction within the bar. The flux, $\mathsf{B}_1 s_1$, is the quantity which the ballistic test measures. The equation may be written

$$4\pi C N = \frac{\mathsf{B}_1}{\mu_1}\left(l_1 + \frac{\mu_1 s_1}{\mu_2 s_2} l_2\right).$$

Now H, the true magnetic force acting on the bar, is $\frac{\mathsf{B}_1}{\mu_1}$; hence

$$\mathsf{H} = \frac{4\pi C N}{l_1 + \frac{\mu_1 s_1}{\mu_2 s_2} l_2}.$$

The magnetic resistance of the block therefore virtually adds a small piece to the length of the rod—a piece, namely, whose length is $\frac{\mu_1 s_1}{\mu_2 s_2} l_2$, and the effect is that the actual magnetic force is equal to the force due to the magnetising solenoid $\frac{4\pi C N}{l_1}$ *minus* a small correction, the amount of which may be written thus:

$$\mathsf{H} = \frac{4\pi C N}{l_1} - \frac{\mathsf{B}_1 s_1 l_2}{\mu_2 s_2 l_1}.$$

This correction may be made insignificantly small by using for the yoke a material of the greatest possible permeability, and giving it an area of section very many times greater than that of the bar.†

The amount of the correction is not constant, even when expressed as an addition to the length of the bar, for μ_1 and μ_2 are functions of the magnetic state of the bar and yoke respectively, and bear no constant proportion to each other. In all that has been written regarding the magnetic circuit, μ has simply this meaning, that it is the ratio of the induction which happens to exist at the moment, to the magnetic force which happens to exist at the moment. The value of the correction depends, therefore, not merely on the magnetic force actually in operation, but on the previous magnetisation of the circuit. The correction may, of course, be very completely made by the graphic process which has been described, provided we have data from which to draw a curve of B and H for the material of the yoke.

We have spoken of this magnetic circuit as if it were wholly made up of the bar and the yoke. In fact, however, there is another constituent, the importance of which will be more apparent presently. This is the joint at each end of the bar; between the bar and the yoke. We shall see immediately that a joint, that is to say, a discontinuity in the substance of the magnetic circuit—even when there is no perceptible space separating the parts—interposes some resistance. Its effect is equivalent to that of a very narrow air-gap.

Acting like an air-gap, each joint in the circuit tends to shear over the curve of magnetisation, and one effect is that the residual magnetism of the circuit is reduced. This is a rather serious objection to the use of the yoke for determining the permeability of soft iron.

§162. **Magnetic Resistance of Joints.**—The fact that a joint offers magnetic resistance seems to have been first noted by J. J. Thomson and H. F. Newall, who found that when an iron bar was cut in two, and the pieces were put in contact, the susceptibility of the bar was considerably reduced.*

In the following experiments† a tolerably full examination was made of the influence of a joint in adding magnetic resistance to an iron bar, both when the surfaces of the joint were placed in simple contact, and when they were pressed close by externally applied force. The bar was a turned piece of wrought iron, 0·79 cm. in diameter, and it was tested by the ballistic method within a yoke which allowed a clear length of 12·7cms. of the bar to be exposed. Over the whole of this length a magnetising coil was uniformly wound: the magnetising forces which will be stated below are the forces due to this coil. The area of cross section which the yoke provided for the return of lines of induction outside the bar was more than one hundred times greater than the cross section of the bar; nearly the whole magnetic resistance of the circuit was, therefore, that of the bar itself, and of the joint, or joints, in it. The magnetisation of the bar was tested by observing the transient current induced in a small secondary coil, wound at the middle of the length, when the current in the magnetising coil was reversed. Successive observations were made in this way, with magnetising currents that were progressively increased, to determine in each case a curve connecting B in the bar with the magnetising force of the coil.

The bar was first tested without any cut, and then when cut in the middle into two parts, the ends of which were carefully scraped to form true planes before being put into contact. The truth of the surfaces which formed the joint was tested by comparison with a Whitworth surface-plate. Notwithstanding the closeness of contact which this procedure ensured, the joint was found to offer a very appreciable amount of resistance, as the following figures will show:—

Table XXVI.—*Influence of a smooth joint in reducing the magnetic induction in an iron bar.*

Magnetising force due to solenoid.	Magnetic Induction B.	
	Bar uncut.	Bar cut in two pieces with surfaces of the joint faced to be true planes.
4	3,950	3,000
6	6,900	5,300

§163. **Calculation of the Equivalent Air-gap.**—The influence of a joint in adding magnetic resistance may be conveniently expressed by calculating the width of an air-gap which would have the same resistance, assuming the permeability of the metal itself to be wholly unaffected by cutting. The width of the equivalent air-gap is readily found in the following way‡:—

Let H_1' be the magnetising force due to the solenoid when the bar is uncut, and H_2' the magnetising force due to the

* All rights are reserved.

† See Hopkinson, *Phil. Trans.* 1885, p. 458.

* *Proc. Camb. Phil. Soc.*, 1887.

† "On the influence of a plane of transverse section on the magnetic permeability of an iron bar (by the writer and W. Low)."—*Phil. Mag.*, Sept., 1888.

‡ In the Paper from which these experiments are quoted an erroneous procedure was followed in calculating the width of the equivalent air-gap. The error had the effect of making the gap appear to diminish in thickness as the magnetisation was strengthened. The figures given here are corrected.

Digitized by Google

solenoid when the bar is cut, both for the same value of **B**. Let l be the length of the bar, and s its area of cross section. Let x be the width of the air-gap equivalent in magnetic resistance to the joint. Then, by the principle of the magnetic circuit

$$H_1' l = \frac{B l}{\mu},$$

and

$$H_2' l = \frac{B l}{\mu} + B x.$$

Since **B** is the same in both cases, μ is the same. Hence,

$$B x = H_2' l - H_1' l,$$

and

$$x = \frac{(H_2' - H_1') l}{B}.$$

To find x, we have therefore to draw curves of **B** and H_1' and of **B** and H_2', and measure the horizontal distance from one curve to the other, that is to say, the difference of H' for the same value of **B**. The quantity $H_1' l$ is the magnetomotive force that suffices to produce the induction **B** when the bar is uncut. The quantity $(H_2' - H_1') l$ is the additional magnetomotive force that is required to force the same induction **B** through the joint.

In Fig. 134, the curves are drawn for the experiment which has just been quoted, and the values of $H_2' - H_1'$ are represented by the slightly curved line at the side of the figure. This line is not far from straight—which implies that the width of equivalent air-gap is not far from constant throughout the range of

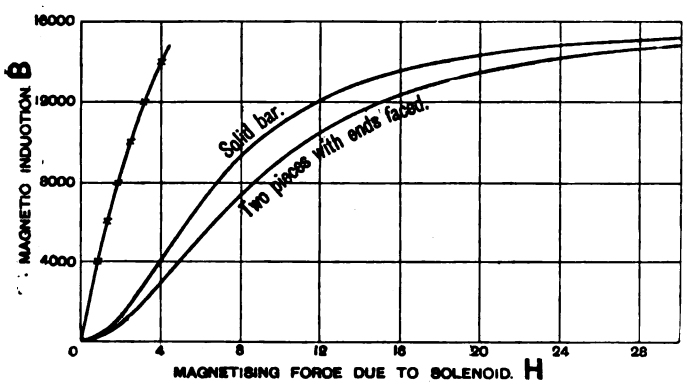

Fig. 134.—Influence of a Smooth Joint on the Magnetic Resistance of an Iron Bar

values of **B** with which the experiment deals. This curve does, indeed, incline slightly outwards at the higher values of **B**, implying a greater width of equivalent air-gap in the region of strong magnetisation; but it may be questioned whether this slight deviation from straightness may not be due to errors of observation. A very slight error in the value of **B** in one or other of the two curves would suffice to account for it; and in another precisely similar experiment, made with another bar, the line showing values of $H_2' - H_1'$ actually bends slightly *inwards* at high values of **B**. It appears, then, that the joint is equivalent, in magnetic resistance, to a narrow gap of air, the width of which is at least not far from constant. The following are the widths of this gap calculated for the experiment of Table XXVI. and Fig. 134.

B.	Width of equivalent air-gap in centimetres.
4,000	0·0026
6,000	0·0030
8,000	0·0031
10,000	0·0031
12,000	0·0035
14,000	0·0037

The corresponding quantities in another and quite independent experiment, made with a different iron bar, were:—

B.	Width of equivalent air-gap in centimetres.
6,000	0·0043
8,000	0·0041
10,000	0·0036
12,000	0·0030

In this case, as in the other, the ends of the bar after being cut were carefully brought to the condition of true planes.

We may take a width of 0·0033cms. to represent fairly the equivalent gap in the first case, and 0·0036cms. in the second. These figures agree with one another as well as the circumstances of the measurement would lead one to expect. The equivalent gap is not very wide, but it is difficult to believe that the surfaces of the metal were actually separated by even this narrow space. It seems more probable that the magnetic resistance of the joint is due in part to a diminished permeability in the metal itself at and close to each surface, and this conjecture receives some support, as may appear later, from the theory which ascribes the process of magnetisation to the arrangement of molecular groups.

§ 164. Influence of Compression on the Magnetic Resistance of a Joint.—Other experiments in the same series* were directed to examine how the magnetic resistance of a joint is affected when the surfaces are pressed into close contact. The method of the yoke was still employed; the yoke was placed so that the bar stood vertically, and compression was applied to the bar by means of a weighted lever at the top, and a stop at the bottom, as in Fig. 97, § 122. In experiments of this kind it is, of course, necessary to remember that the permeability of the metal itself is changed by compressive stress; the influence of the joint is to be tested by comparing the resistance of the cut bar under pressure with the resistance of the uncut bar under equal pressure. It was found that the effect of pressure is to lessen the magnetic resistance of the joint, so much so, indeed, that when the surfaces composing the joint are true planes, a tolerably strong compressive stress almost wholly destroys the resistance of the joint, and restores the divided bar all but perfectly to the magnetic condition of an uncut bar. This effect was produced almost completely by a stress, the intensity of which was 226 kilogrammes per square centimetre. Under this load a curve of **B** and H' taken for the cut bar was practically indistinguishable from the curve taken for the solid bar. Smaller loads only reduced the resistance of the joint without making it disappear, and a progressive reduction of the resistance could be traced as the loads were increased. The following table gives the values of **B** which were observed in an iron bar, first when solid and then when cut in two parts with faced ends, under various stresses, the magnetising force due to the solenoid being brought to the same value (5 C.-G.-S. units) in each case. This magnetising force was applied after each load had been put on.

Table XXVII.—*Influence of compressive stress in reducing the magnetic resistance of a joint.*

Stress in kilos. per sq. cm.	Magnetic Induction **B**, produced in each case by a magnetising force in the coil (H') of 5 C.-G.-S. units.	
	Before Cutting.	After Cutting.
0	5,600	4,700
56·5	5,400	4,670
113	4,700	4,200
169·5	4,050	3,800
226	3,650	3,650

Here, under the highest stress, the disappearance of the joint's resistance was complete for a magnetising force of 5 C.-G.-S., but under stronger magnetising forces it was hardly so perfect.

In connection with these results it may be noted that the magnetic traction, $\left(\frac{B^2}{8\pi}\right)$ amounting, as it does, to less than 1 kilogramme per sq. cm., when **B** is 5,000, is insignificant in comparison with the stress produced by external loading.

THE OERLIKON THREE-PHASE ALTERNATOR.

The electric transmission of power for industrial purposes has now become an every-day affair, and, owing to the distances which in the majority of cases separate the waterfalls from the places where their energy is to be utilised, high pressures are necessary. Owing to the ease with which they lend themselves to transformations of pressure, and for other reasons, alternating currents are eminently adapted to the purpose, and when these currents are of the multiphase character, satisfactory motors are also forthcoming. The Oerlikon Works, which have for long made a speciality of transmission of power installations, are about to lay down several plants on the multiphase system, devised by Mr. C. E. L. Brown.

In Fig. 1 we have a general view of a 300 H.P. Brown "multiphaser," running at 150 revolutions. The armature circuits are arranged to give three alternating currents lagging 120deg. one behind the other. Each of the three circuits of the machine is wound for a pressure of 50 volts and a current of 1,400 amperes. The current output being large, rubbing contacts have been avoided by making the armature stationary and the field-magnets revolve. The armature conductors are 29mm. in diameter, and consist of massive bars of copper, insulated inside asbestos tubes, and buried in holes punched out of the iron close to the internal periphery. Foucault currents, which would attain enormous values in such large copper conductors, if they were arranged in the ordinary way, are by this device avoided; in fact, experiments made with "buried" conductors, 50mm. in diameter, did not show that any power was lost by Foucault currents. This method of arranging the armature conductors is mechanically strong, and, as it enables asbestos to be used as an insulator, results in an armature which is absolutely incombustible. Moreover, the reduction in the air space, and the consequent improvement of the magnetic circuit, reduces the exciting current.

Corresponding to the 32 poles of the field-magnet, each circuit of the armature has 32 copper bars, connected in series by transverse pieces. There are, therefore, in all 96 (3 × 32) bars on the armature. The three circuits are joined up to each other in a manner similar to the three circuits of the Thomson-Houston arc machine. The armature core is surrounded by a cast-iron frame, and the whole can be moved along the bed-plate for cleaning and other purposes, leaving the field-magnet open to view, as shown in Fig. 2.

The exciting circuit is coiled round a sort of cast-iron pulley. Two steel rims, each armed with 16 horns forming pole-pieces, are bolted on to the pulley, one on either face, in the manner shown in detail in Figs. 3 and 4. This arrangement permits of the maximum utilisation of the magnetic flux, and both the copper and the exciting current are reduced to a minimum. The construction of a field magnet of this type is very simple, the 32-pole magnet being only in four separate parts, an inestimable advantage in a piece of moving mechanism subject to heavy stresses.

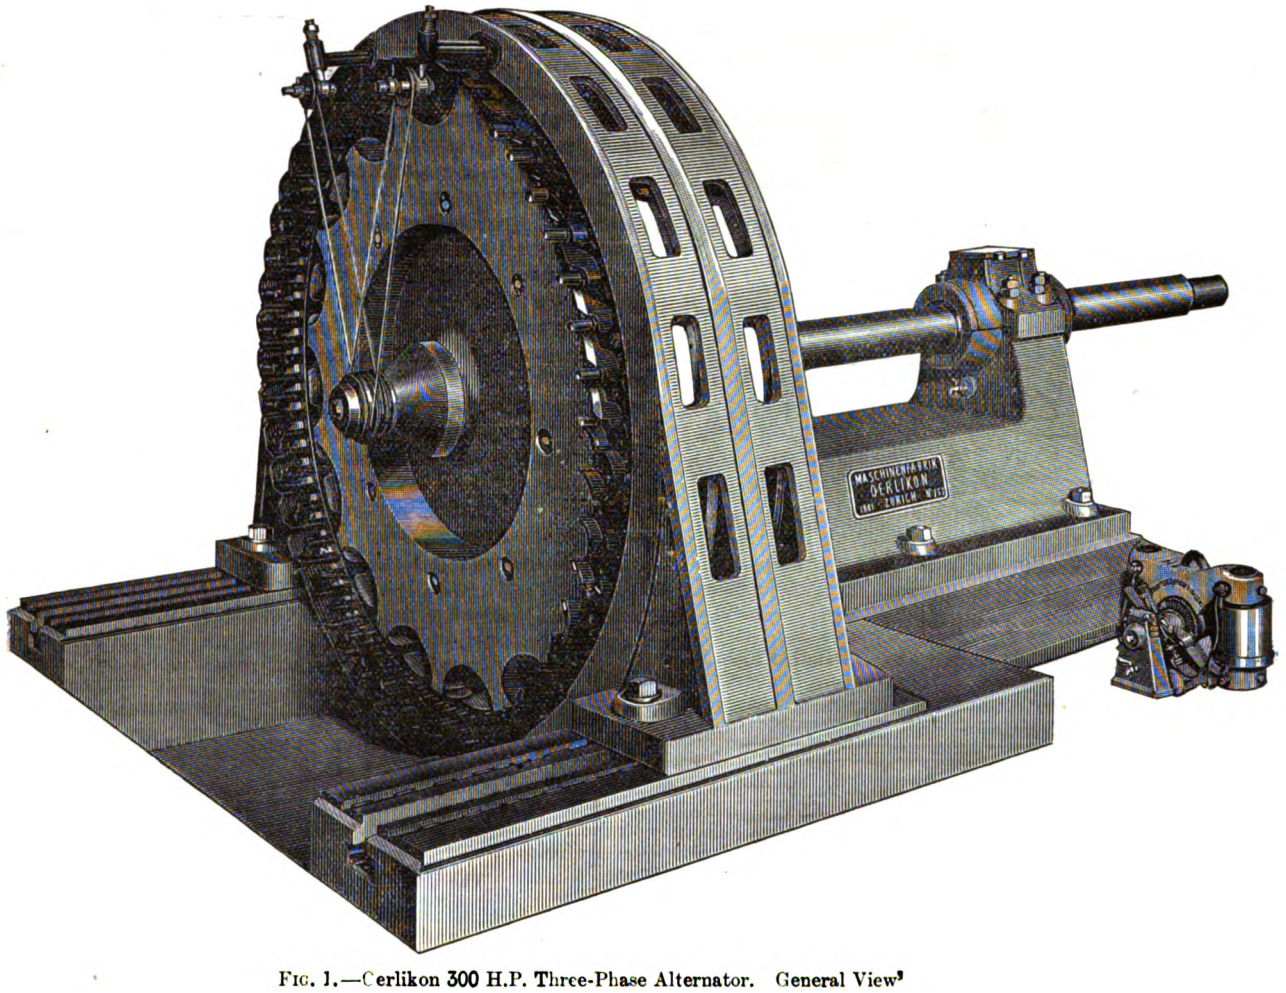

FIG. 1.—Oerlikon 300 H.P. Three-Phase Alternator. General View.

The exciting current is taken to the field magnets by means of two metallic bands, each of which passes round a grooved ring on the spindle, and round a pulley connected to a terminal. (See Fig. 1.) The armature is overhung, the massive spindle being carried on a double bracket bolted to the bed-plate.

A machine of this type can work equally well as a synchronising motor, but it differs from an ordinary alternate current motor, inasmuch as it can be made to start without difficulty.

A few figures may not be without interest. The total weight of copper on the field magnet is 300 kilogrammes; that is to say, a fraction of the copper usually required for other machines of the same size. To excite the machine so as to give 50 volts on open circuit, only 100 watts are required; that is to say, one-twentieth per cent. of the output. At full load, owing to the reaction of the armature, this amount is slightly increased, but it never exceeds a fraction of one per cent. At

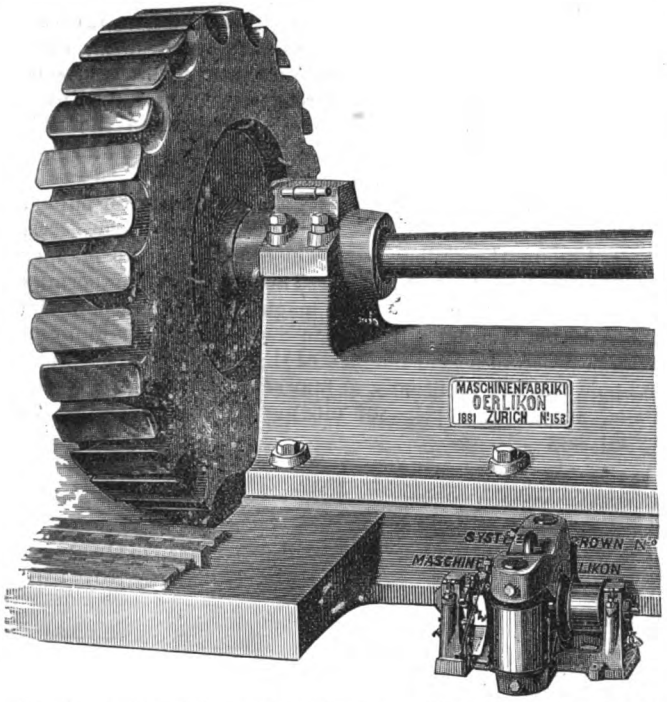

FIG. 2.—Oerlikon Three Phase Alternator. View of Field Magnet with Armature removed.

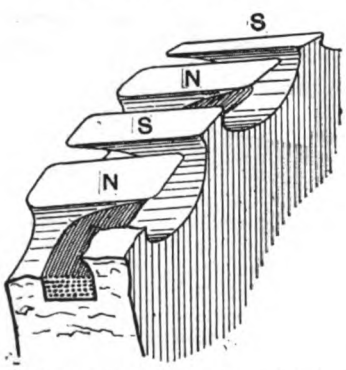

FIG. 3.—Oerlikon Three Phase Alternator. Detail of Field Magnet.

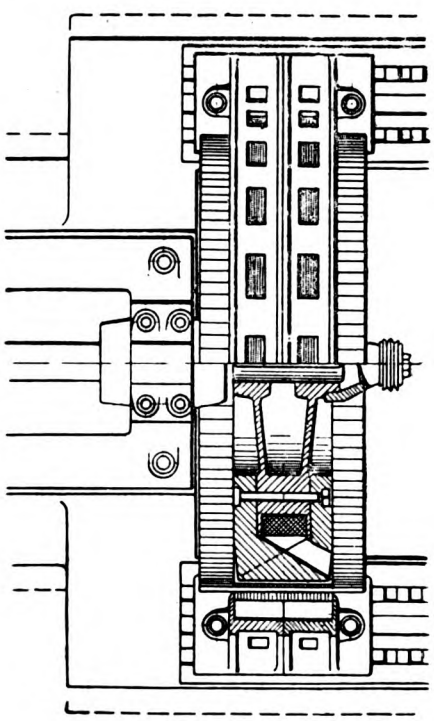

FIG. 4.—Plan and Half Section of Dynamo, showing Construction of Field Magnets.

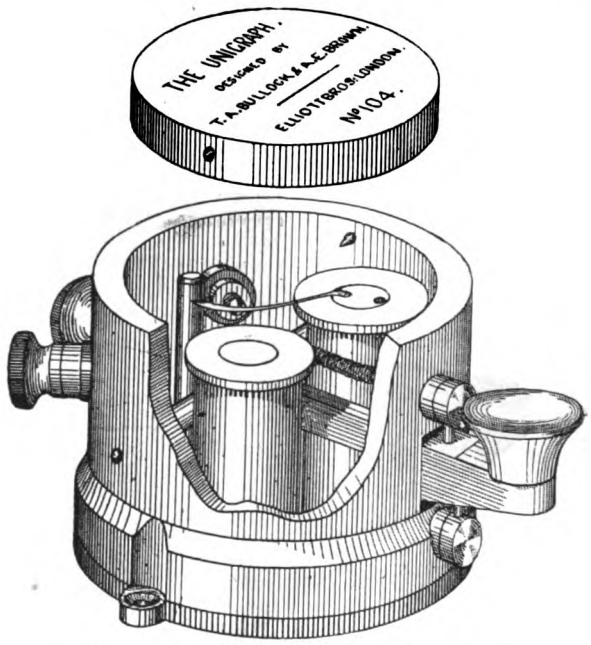
full speed, and with normal volts, the friction losses amount to 3,600 watts, about 1·6 or 1·7 per cent. of the maximum output. The C^2R loss in the armature at full load is 3,500 watts. Adding all these losses up, we still have a commereial efficiency of 96 per cent. With such small losses the heating is, of course, quite negligible. The total weight of the machine without bed-plate is 9,000 kilogrammes.

The Oerlikon Works have completed, or have in the course of construction, several dynamos of this type. First of all comes the Lauffen-Frankfort transmission plant. Machines are also building for 10 kilometre transmission at Heilbronn, and at Zürich ; while three generators with vertical spindles, for coupling direct to turbines, and two motors with horizontal spindles are to be employed to drive the whole of the machinery at the Oerikon Works from a waterfall 23 kilometres distant.

THE UNIGRAPH.

An ingenious little telegraph instrument, combining in one small and compact space a sending key, and a loud speaking sounder, is being made by Messrs. Elliott Bros., under the name of The Unigraph. The accompanying illustration represents the instrument full size, the circular armature being removed, and the side broken away to show the interior. The base



The Unigraph, with Hollow Disc Armature removed.

is of iron, and acts as a yoke. The armature, or keeper, forms one of the special features of the invention. It is in the form of a hollow disc, instead of the bar or tube generally employed. The form and thickness of this disc is so arranged that an unusually loud and clear sound is given for a small current. The disc is mounted to rock on centres, and is pushed away from the magnets by a light spring between them, as shown in the illustration. The outer box is only 2 inches in diameter, and stands $1\frac{3}{8}$ inches high. It is suggested by the inventors that this form of instrument is particularly suitable for students and learners, and for use in military telegraphs, on account of its simplcity and clear speaking.

The Society of Arts and the Chicago Exhibition.—Forms of application for space, and prospectuses, with detailed information, will not be issued till October; but, in the meantime, intending exhibitors can apply to the Secretary of the Society of Arts, and their names will be noted at once, with a view to their receiving early copies of the prospectus, when ready.

EXPERIMENTS WITH CONDENSERS.*

BY MAURICE LEBLANC.

I experimented with two types of condensers, namely, some made of paraffined paper and intended for medium pressures up to 2,500 volts, and others made of ebonite.

The first, constructed by M. Labour, gave such singular results, that they seem to me worthy of being placed on record. Paper of very mediocre quality and common paraffin heated to 70°C. were employed. Their capacity, as measured in the ordinary way, showed that the dielectric possessed a specific inductive capacity of about 8, but the residual discharge was about one-fourth of the first discharge. If their capacity was measured by applying an alternating current of 75 ∿ and known strength, and noting the difference of potential at the terminals, it was found that the apparent specific inductive capacity was one-third less than that previously determined. Finally, when they were subjected to the continuous action of an alternating potential difference of between 1,500 and 2,000 volts, they quickly heated, the paraffin melted, the condensers began to "hum," and if the experiment was not terminated the condensers were soon destroyed.

I at first attributed this result to the inferior quality of the material employed, but no sensible advantage was gained by using the best paper and paraffin. Endeavouring to explain the phenomena observed, it occurred to me that, paper being an organic substance, each of the constituent cellules enclosed an extremely minute drop of liquid. Similarly, the paraffin might contain traces of the sulphuric acid which had been used to purify it. We were, therefore, dealing with the dielectric whose properties were investigated by Poisson, namely, a perfect dielectric studded with conducting spheres. The high specific inductive capacity and the heating when in operation were thus explained.

It seemed probable that if the paper were previously heated for several hours in paraffin at the temperature of dissociation of this substance, the organic constitution of the paper would be destroyed, and the paraffin would give up any trace of acid that it might contain. Experiment confirmed this idea. The paper, on being taken out of the paraffin, had completely changed in appearance, increased in thickness, and every trace of fibre had vanished. The specific inductive capacity of the dielectric had been reduced to 2, 5, 6; the residual discharge had become insignificant, and condensers made of this material no longer got hot. But this method of preparing the paper is very expensive, owing to the large amount of paraffin which is decomposed. Moreover, the sheets sticking to one another, it is necessary to keep them hot in order to separate them as required, which is a difficult and delicate operation, and results in a great increase in the cost of construction.

While these condensers were being made several experiments were carried out on the first ones, which, being considered defective, were extremely badly treated, and had often to withstand a potential difference of 4,000 volts. Later on, requiring to measure the capacity of some of these, I was surprised to find it much less than was anticipated. The specific inductive capacity of the dielectric had become 2·56. As it seemed logical for the heating effect to have also diminished, the experiment was tried and fulfilled anticipation. These condensers, which were so defective at the commencement, no longer heated, and had become excellent. To clear the matter up completely a second set of similar condensers were made, and were kept at work for several days, their increase of temperature being carefully noted. Everything fell out as was expected. The condenser heated less every day, and at the end of ten days of nearly continuous experimenting, at a pressure of 1,500 volts, they became equal to the first lot. It follows from this that excellent results may be obtained with condensers of paraffined paper, and that one need not trouble oneself about the quality of the material so long as it undergoes a process of formation as described. Condensers must not be put into operation without careful attention, and they must be cut out of circuit as soon as they heat up sensibly.

The following, by-the-way, is a practical and easily observed rule:—A condenser which works without emitting any sound whatsoever is in no danger; as soon as it begins to vibrate it is in danger.

It is easy to understand that that which the action of heat was able to effect in a few hours (about three on an average) the electric displacement which was taking place among all the conducting particles enclosed in the mass was able to effect slowly. This brings into prominence a property of alternating currents which is now generally recognised, namely, that their action on dielectrics is beneficial rather than deleterious. It is easy to show this. Under the influence of steady potentials all the conducting molecules confined within a dielectric take up a definite position once for all, like the anions and cathions of an electrolyte. These molecules tend to move towards one another, which they can only do by opening a path through the dielectric and changing its constitution. Under the influence of alternating potential differences, there is electric displacement in the heart of the conducting mass itself. Now, I have never been able to pass an alternating current through a liquid, even when the current density was very low, without bringing about a trace of liberation of gas. Is it not logical to suppose that the same thing takes place in the conducting molecule itself, and that the gaseous products never entirely recombine? They could not, indeed, do so, for there is no system of transformation having an efficiency of unity. In this way can be explained the fact that all imperfectly conducting substances which can only transmit electricity after the manner of electrolytes, and which are confined in a dielectric, are destroyed in time under the influence of alternating potential differences before the mass of the dielectric has been sensibly impaired by the mutual action of these molecules.

Ebonite condensers gave entire satisfaction. The capacities, measured by the ordinary methods, or by means of alternate currents, were the same; the residual discharge was insignificant. Lastly, they did not heat. The tinfoil was fastened on to the ebonite sheets either with chatterton or "arkanson," melted and placed on with a brush. The ebonite sheets were kept on a hot plate until they became soft and very supple. The tinfoil was applied by means of an ordinary hot iron. Chatterton seemed to be the best cement. Condensers made in this way were regular solid planks. The thinnest ebonite that I was able to procure was ·2mm. thick. I was not able to break this sheet down under a pressure of 11,000 volts—the highest obtainable.

Celluloid also yielded good results as a dielectric, but I gave up the idea of employing it owing to its inflammability, a spark being enough to set it alight. The variety known by the name of American linen does not, however, possess this defect to the same extent, and if the experiments on this material were not continued it was only because I was finally able to get ebonite at a very low price; that is to say, at 6·5frs. the kilogramme when ·5mm. thick, and 12frs. the kilogramme when ·2mm. thick. It was this ebonite which I tested.

When the pressure applied to a condenser is raised considerably, a *frizzling* noise is heard, and an odour of ozone is at the same time perceptible. In my experiments an inductive coil was made use of, the iron rod of which vibrated naturally twice as rapidly as the current. The *frizzling* noise which was heard seemed always to be two octaves higher than the note given out by the rod. I attributed it to lateral discharges due to the higher harmonics of the current. If this be so, it should be possible to suppress it by increasing the space separating the edge of the tinfoil from the edge of the dielectric. This was found to be possible. It is, however, necessary that this distance should be at least 5cm. if one wishes to avoid all rustling noise when the pressure exceeds 11,000 volts on the electrometer.

* Extract from a Paper entitled "De l'Application des Courants Alternatifs à la Transmission du Travail," read before the Soc. Inst. des Electriciens, July 1, 1891.

ON THE DETERMINATION OF THE MAXIMUM CONDUCTIVITY OF VERY DILUTE SOLUTIONS OF COPPER SULPHATE.*

BY P. SACK.

Arrhenius theoretically proved that the conductivity of an electrolyte must possess a maximum value at a certain temperature. For phosphorous and phosphoric salts this maximum lies at 54deg. and 73deg. respectively, as he found experimentally. The author conducted similar investigations for three very dilute solutions of copper sulphate, and found the maxima to be as follows:—

Strength of solution per cent.	Temp. maximum conductivity.
·321	94°C
·500	95°C
·642	96°C

The resistances were measured by Kohlrausch's method with a Wheatstone bridge, an alternating current, and a telephone. The resistance was prepared as follows:—Two egg-shaped glass vessels were connected underneath by a glass tube, and each had a small tube fixed into its side. These served to fill the glass vessels, and after this was done they were sealed up. Platinum wires were fused through the upper part of the vessels, and were provided with concave cup-shaped electrodes.

With this arrangement no movement of the electrodes is possible, the degree of concentration cannot be affected by evaporation, and the liquid can be heated above its boiling point. In the latter case an explosion of the glass must be guarded against. The vessels were made of potassium glass, and the warming was effected by an air bath.

STEEL-PLATE PORTRAITS

Of W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Past-President of the Institution of Electrical Engineers); C. H. B. Patey, C.B. (Late Secretary of Telegraphs, G.P.O.); Dr. John Hopkinson, F.R.S. (Past-President of the Institution of Electrical Engineers); Dr. Oliver J. Lodge, F.R.S., and Prof. William Crookes, F.R.S. (President of the Institution of Electrical Engineers), have been issued as Supplements to "THE ELECTRICIAN." *A few Copies of these admirably-executed Steel Engravings can be supplied, price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, post free, 4s. 6d.*

THE POSTAL TELEGRAPH ESTIMATES.

A great part of last Saturday's sitting in the House of Commons was taken up with a discussion of the Postal and Telegraph estimates for the year. Probably no Vote that comes before the House is less open to criticism than that of either the Post Office or the Telegraph services, yet hardly any receive more attention. The reason is not far to seek. A surplus of from three to four millions is, so to speak, ready to hand, and anybody who has a hobby to ride or a grievance to air is eager to demand his share of the good things going. Why the Post Office revenue, much more the Telegraph, should be regarded as profit and available as surplus, whilst that of the Custom House and other taxing departments of State is treated as too sacred to be touched, is somewhat unintelligible. Certainly, whatever profits the Post Office or the Telegraphs may be able to cast into the Treasury are a relief to the general taxation; and surely no form of taxation could be less vexatious or less burdensome than the charges on letters and telegrams. Already these services are as cheap in this country as in most, and cheaper than in many; while as regards efficiency and expedition, no other country can rival this. Until recent years, the profits derived from Postal business were accepted as aids to national revenue — in other words as relief

Digitized by Google

of taxation; but latterly, an outcry has been raised against this source of income, not, however, because of its demerits, but because certain ingenious persons are ever ready to find other ways of disposing of the money than putting it into the National Treasury.

As regards its effects on the Postal revenue, the activity of these critics is of no great consequence. Mr. RAIKES can well afford to appease their appetites by sacrificing a few hundred thousand pounds now and again; and the service has certainly benefited by the manner in which he has disposed of the money. But it is quite a different matter when similar demands are made upon the Telegraph revenue. In public estimation the two services are one; and the result is that every penny saved out of Telegraph earnings is subject to the same extravagant demands as are the profits of the Postal Service. This year there has been a surplus for the first time since the introduction of the sixpenny rate—a surplus, if we rightly understand the POSTMASTER-GENERAL's statement, even after paying the interest on capital. No sooner is this point reached than a serious effort is made to appropriate the margin, and we are sorry to notice that some sort of encouragement was given to the raiders last Saturday afternoon. For many years past the fact that the State Telegraph Department was carried on at a loss protected it from encroachments of that kind, and was, perhaps, the only valid excuse remaining for keeping the accounts separate from those of the Postal Service. But now that a remunerative period has set in, its connection with the richer department threatens to work to the disadvantage of the Telegraph, by bringing it within range of the Post Office reformer. This class of person is possessed with the idea, as enunciated by Mr. SHAW-LEFEVRE the other day, that "there never has been any improvement made in the service at a considerable expense which had not ultimately led to an increase of the revenue at least equal to the cost." The telegraphs were acquired "at considerable expense," and if their acquisition may be regarded as an "improvement in the service," Mr. SHAW-LEFEVRE's statement is contradicted by the result, as he himself admits a little further on, But if the Post Office is to be credited with the improvement, it is high time it took up the burden, and relieved the Telegraph of the financial difficulties it will again have to encounter if any further demands upon its resources are yielded to.

In a general way we do not attach much importance to that section of Post Office critics represented by Mr. HENNIKER HEATON; but he has suddenly become a serious danger to the Telegraph Service by reason of a reply which he elicited from the POSTMASTER-GENERAL on the discussion of the Telegraph Vote. The member for Canterbury is apprehensive that the Telegraph Service may soon become what the Post Office is, a profit earning department; and as a means of averting this peril he entreated MR. RAIKES to "carry out as early as possible the reform of having an address not exceeding eight words sent free." To this the POSTMASTER-GENERAL, without committing himself to any definite proposition, expressed an opinion that some relaxation in respect to addresses was desirable, and stated that he would be glad if at some future time the Treasury might allow them to be put upon a rather more liberal footing. If we may take this as a deliberate announcement it can mean little less than that we are at some not distant day to have a 20-word in place of the 12-word tariff. It will be a long time before the revenue can really afford such a sacrifice, or the existing plant bear the strain of extra work such as that would involve. The normal telegram at present averages 16 words, for which 8d. is paid. It follows that the public, being willing to spend 8d. on each telegram, will spend nearly as much if the minimum of 12 words were increased to 20. That is to say, the average telegram would then contain nearly 24 words. If any one doubts this prediction we would remind him that the average length of the telegram under the old tariff, with free addresses, exceeded 30 words, although the cost was 1s. Notwithstanding all this, Mr. HENNIKER HEATON is not the man to allow his occupation to go by default, and having now in prospect another brilliant reform, for which he may some day take credit, he will never cease from troubling until the question is settled one way or another for good and all.

The sooner, therefore, it is gone into the better. So far as the public is concerned we believe that, while taking the fullest advantage of every concession, it is content with the tariff as it stands. That tariff is consistent and intelligible, a charge being made for every word signalled. If it can be shown that the finances will bear it, no one can object to an extension of the 12 words limit, though it must be clearly understood what such a privilege represents in money; and on no account should the Telegraph Service be starved in any way for that object. But, unfortunately, Mr. RAIKES's language, if correctly reported, goes beyond a mere extension of the limit, and practically concedes all that has ever been said against taxed addresses. Even if the 12 words limit were enlarged to 20, it would leave the clamour for free addresses unappeased in the face of what was officially stated last Saturday. We can only hope that the words let fall then will be unsaid so soon as the figures are gone into. All that we need say on that part of the subject at present is that there is no stopping place between taxed addresses and free addresses. It could easily be shown that there is no logical reason for taxing the sender's address, while the addressee's goes free; and Mr. HENNIKER HEATON well knows that to create two limitations—two sets of counting—in the same message would be so inconvenient to the servants of the Telegraph Department that enfranchisement for both addresses altogether must speedily follow.

AN IMPERIAL STANDARD OF LIGHT.

A good deal of stir was made by electrical engineers some years ago for a better standard of light than the Parliamentary candle. The only practical result brought about was the development of the pentane lamp into its present state of excellence. The suggestions about which most fuss was made were the most impracticable, and it was doubtless thought by the Board of Trade that the agitation was but part of the enthusiasm with which electric light was received. The delay was reasonable, not only that matters might settle down before attempting to decide whether a new standard was really wanted, but to allow time for the construction of some simple and thoroughly trustworthy standard. The Gas Companies have now taken the matter up again, and they are driven to this by the zeal with which the County Council is enforcing the regulations as to illuminating power of the gas supplied. They protest against the absence of any standard of the photometers which are used against them, and the Sanitary and Special Purposes Committee allude in their recent report to this, and refer to the strong representations which they have made to the Board of Trade as to the necessity of amending the Gas Acts. In 1881, a Photometric Committee, appointed by the Board of Trade, reported adversely on the existing standard, and suggested one which was trustworthy. Since that time experiments and observations made under the direction of the Royal Society, of the Metropolitan Board of Works, and of other bodies, have shown that the standard of light suggested by the Committee of 1881 was a satisfactory one.

Digitized by Google

At the meeting of the London County Council, last Tuesday, the Sanitary and Special Purposes Committee presented a report on the subject of a proposed amendment of the law relating to testing of gas in the Metropolis. They say that at various times they have reported to the Council the steps they have taken for obtaining an amendment of the law in relation to the standard of light. The Acts which regulate the gas supplied to London by the principal Gas Companies require that the illuminating power of gas shall, when consumed at the rate of 5 cubic feet per hour by means of a standard Argand gas-burner, be equal in intensity to the light given by 16 sperm candles, six to the pound, each burning at the rate of 120 grains per hour. The standard, says the Committee, is a most unsatisfactory one, owing to the great variation that inevitably occurs in the candles themselves, and, to some extent, in the method of burning them. This uncertainty has been recognised for many years past by all the authorities who are engaged in the manufacture or supervision of gas, and upwards of ten years ago the Board of Trade appointed a Committee, which reported adversely on the existing standard. Since that time many efforts have been made to obtain the substitution of a more satisfactory standard, and the Council has for the past two years been in frequent communication with the Board of Trade on the subject. At the request of the Board, the Council caused to be prepared clauses and schedules for insertion in a Bill, which the Committee understood was to be introduced by the Board for giving effect to the Council's views. After giving these clauses very careful consideration, the Board of Trade thought that the matter was one with which the Council might usefully deal, so far as the question relates to the London Gas Companies. The Board of Trade have undertaken to appoint a Scientific Committee to consider what the standard of light should be; and they ask if the Council would be prepared to bear the expense of such a Committee. The Sanitary Committee were not prepared to advise the Council to bear the cost of this Committee. In the first place, they remarked, the settlement of the standard of light is an Imperial and not a local question; and, in the second, it is questionable if the Council has power to expend money for the purpose. They recommend—"That a Bill be introduced by the Council in the next session of Parliament for substituting a more exact standard of light for that now prescribed by the principal Gas Companies' Acts; and that it be referred to the Parliamentary Committee to take the necessary steps for this purpose." The recommendation was agreed to without debate.

The suggestion that the County Council should spend money in settling a standard of light is a remarkable one. The Board of Trade seem to think that there is no limit to their activity, and because they are ready to meddle with all sorts of matters they only need a little encouragement to carry out work which is most distinctly part of the duties of the Board themselves. A standard of light must, sooner or later, be prescribed, and this means that some kind of lamp or other source of light must be legalised, and, when legalised, the standard candle—for the name will in all probability survive—will be an Imperial standard, like the pound or the yard.

It is true that the Electric Lighting Acts have been modelled after the Gas Acts, and in several cases important sections have been taken *en bloc*, but the fact that a certain (or uncertain) candle is mentioned in them does not confine the matter to an amendment of these Acts. A standard of light is wanted as a standard by which sales may be effected; whether of gas which shall under special circumstances yield a light which shall be measured by this standard, or of burners or glow-lamps which, with a certain quality of gas, or with a certain current, shall give a certain light. The present candle serves only to define the quality of gas which is delivered by the Gas Companies. It was never set up as a standard to which any buyers or sellers could refer. The recommendation which was agreed to by the County Council appears to refer to an amendment, for it proposes to substitute a more exact standard for that now prescribed. The matter should be dealt with under the Weights and Measures Acts, and should be taken under the patronage of the Standards Department rather than that of the Gas Referees.

THE FRANKFORT EXHIBITION.—VI.

(FROM OUR SPECIAL CORRESPONDENT.)

The firm of C. and E. Fein, of Stuttgart, has a most extensive exhibit, of which we give some illustrations below. Fig. 1 shows one of their two-pole machines driven by belt from a single-cylinder vertical engine. The massive field magnets are cast in one piece with the bed-plate; the air space is very small, one layer of wire only being wound on the armature core. Figs. 2 and 3 illustrate two other forms of dynamos manufactured by the firm, and Fig. 4 shows a machine coupled direct to a two-cylinder vertical engine. The dynamo represented in Fig. 2 is a multipolar compound-wound machine. Standard sizes are constructed to give 7, 10, 15, 24, and 36 kilowatts, the number of poles varying according to the output from 4 to 8. Fig. 3 shows the internal pole dynamo manufactured by the firm, the outside guards which protect the windings being removed. In the larger machines of this type a special arrangement is used for ensuring that all the brushes shall simultaneously be brought down upon and removed from the commutator. The 15 kilowatt machine shown (136 amperes × 110 volts) weighs about $1\frac{1}{4}$ tons, and its length, height, and breadth are respectively, 4ft. 4in., 2ft. 9in., and 2ft. 2in. The speed for this size is 500 revolutions per minute, the rotating magnet having four poles. Owing to the low speed

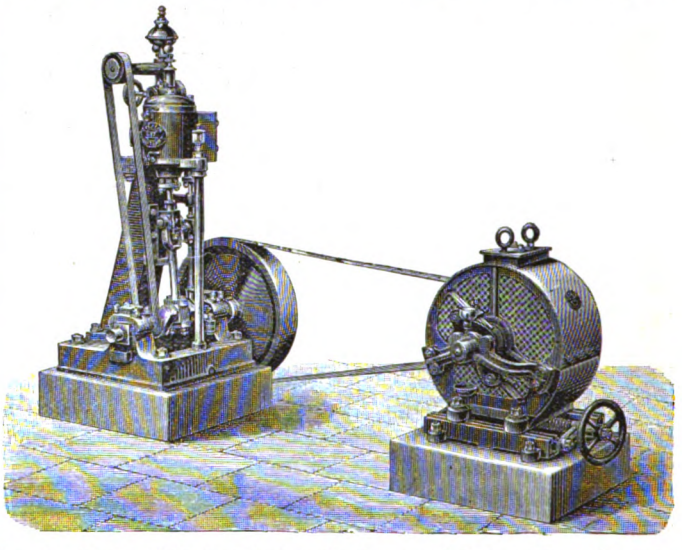

FIG. 1.—Single Cylinder Vertical Engine coupled to a Two-pole Fein Dynamo.

this type of machine is very well adapted to direct driving. They are made in six sizes, from 6 to 46 kilowatts, the speed of the latter being 280 revolutions per minute. The single cylinder engine (Fig, 1) is built in eight sizes, the diameters of the cylinders increasing from $3\frac{1}{2}$in. in the smallest, indicating 5 H.P. at a pressure of 115lb. to the square inch, and 375 revolutions per minute, to 12in. in the largest, giving 62 H.P. at the same pressure, and 170 revolutions per minute. The double cylinder machine (Fig. 4) is made in four sizes, indicating from 36 to 100 H.P. at a pressure of 140lb. per square inch. The speeds of these engines range from 600 to 350. They are fitted with a very sensitive form of governor, which regulates the speeds so well that the difference between the number of revolutions when running light and at full load does not exceed 1 or 2 per cent.

The equipment of the electric lighting waggon (Fig. 5) is very complete. In the middle is a vertical tubular boiler of about 57 square feet heating surface, built for a pressure of about 103lb. to the square inch, but worked usually only at about 73lb. It is supported on the waggon frame, which is constructed of wrought-iron. The boiler tubes are arranged so as to be easily removed for cleaning and repair. The wheels are also of wrought-iron, with broad tyres, to allow of the passage of the conveyance over soft or muddy roads. Under the waggon are the coal box and water tank, the water being heated, before entry into the boiler, by the exhaust steam. At the back of the waggon is a

Digitized by Google

single-cylinder steam-engine. By means of a specially constructed distributing valve motion, governed by a delicate regulator, the machine can be made to run at nearly the same speed at full load and at no load. The lubrication of the bearings and all moving parts is done automatically, and an eccentric on to the crank-shaft works the pump for supplying the water to the boiler, and there is a hand wheel for bringing the crank past the dead points. The dynamo is bolted to a slab of wood, and is so placed as to be easily accessible from all sides. It is driven by a belt, which can be adjusted to the necessary tightness by a hand wheel, moving the dynamo backwards and forwards. The dynamo is compound-wound for 2,400 watts, and has two sets of brushes, one on each side of the machine. A switch is provided, by means of which the dynamo can be made to work either at 65 volts or at 120 volts. There is a second waggon carrying the lamps, posts, coils of wire, switchboard, &c. The equipment includes a large search light and eight arc lamps, six masts, 19ft. 6in. high, six cables wound on drum, each having a length of 160 yards, as well as coils of bare copper wire. There are two switchboards, with current regulators and differential "alarm" voltmeters, which give warning when the electromotive force varies. Among the other exhibits of this firm we may here mention their arc lamp, which burns in any position. A convincing proof of this claim is given in the Machinery Hall, where six of these lamps can be seen slowly revolving, arranged in continuation of the spokes of a wheel, which is driven round by a small electric motor.

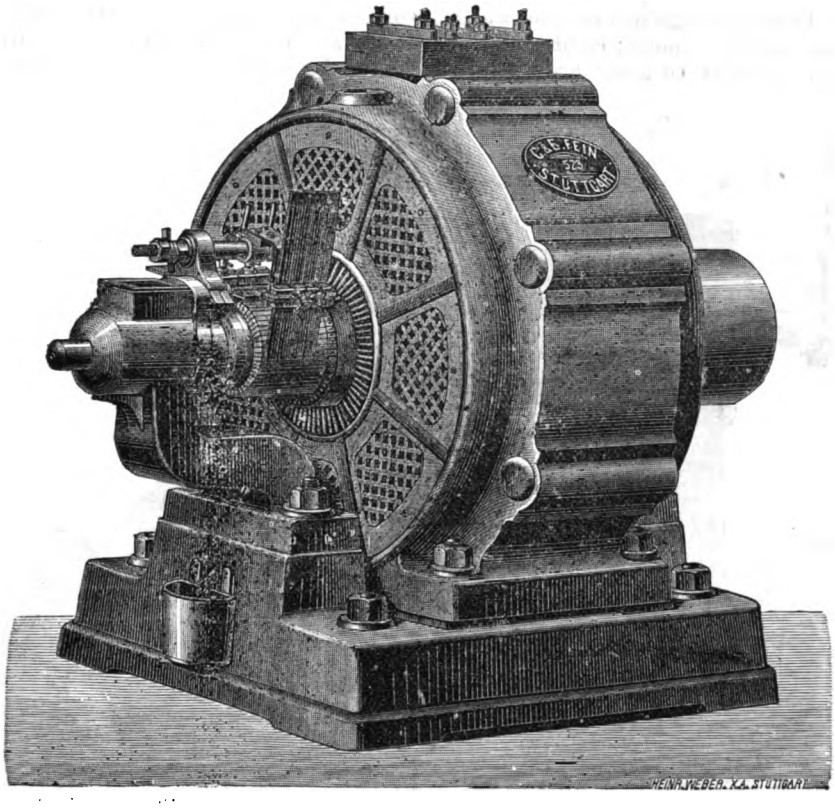

FIG. 2.—Multipolar Compound-Wound Dynamo.

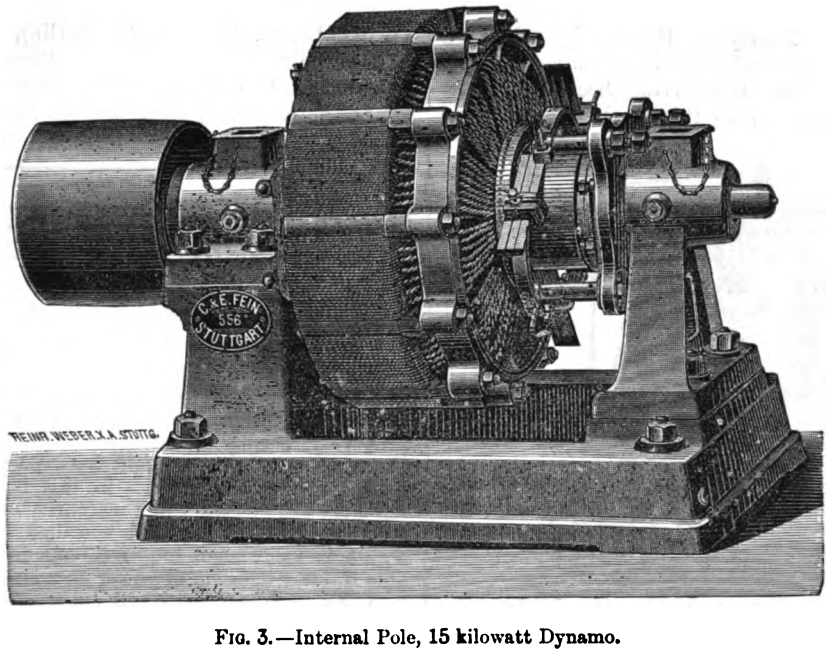

FIG. 3.—Internal Pole, 15 kilowatt Dynamo.

Digitized by Google

The Eastern Telegraph Company has sent a very attractive exhibit to the Exhibition, comprising some of their apparatus of the newest pattern, and also the second syphon-recorder ever made. The other instruments shown are:—Signal relays (Brown), specially constructed for cable working; Saunders's lightning guards, fire-alarms, and the "Unigraph."

The work of erecting the transmission of power line is progressing very rapidly on the Frankfort-Jagstfeld section, which is being erected by the Imperial Government; eight gangs of workmen are busily engaged, whilst three gangs are working on the Wurtemburg side. Nearly all the special telegraph poles are in their places, the unusual difficulties connected with the mountainous nature of the soil having been overcome. The running of the wires commences this week. About two-thirds of a ton of oil will be necessary to fill the insulators. There is now every reason to believe that the three wires of about 120 miles each will be fixed and in working order by middle of August.

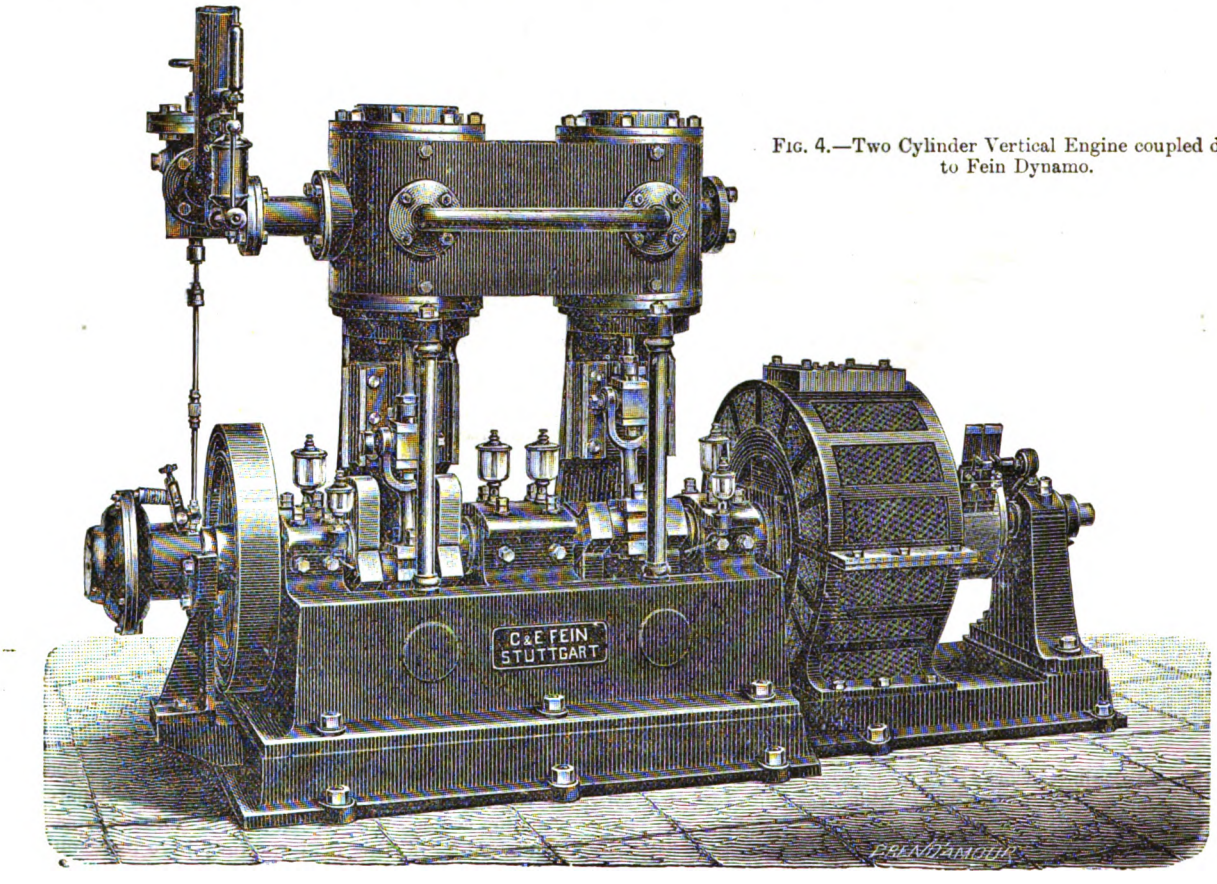

FIG. 4.—Two Cylinder Vertical Engine coupled direct to Fein Dynamo.

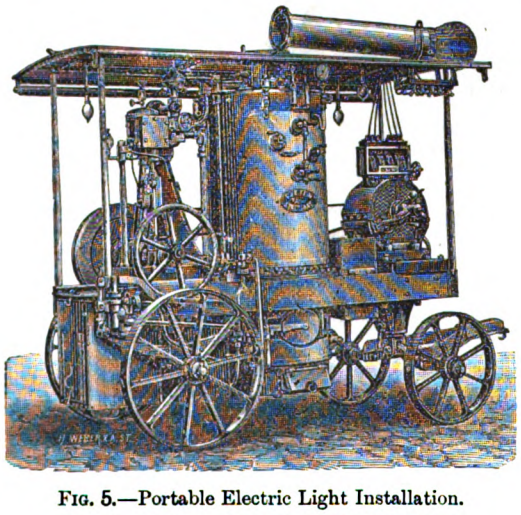

FIG. 5.—Portable Electric Light Installation.

The following are the latest lectures announced for the International Electrotechnical Congress:—"Zipernowsky, "Electric Railways for Rapid Communication between Towns;" Grawinkel, "Accumulators in Telegraphy." Among others mentioned as likely to assist at the Congress are Prof. W. E. Ayrton, Mr. Kapp. Prof. S. P. Thompson, Mr. W. H. Preece, Dr. J. Hopkinson, Mr. J. W. Swan, Mr. C. F. Brush, and Mr. R. E. Crompton; while among engineers from Germany and elsewhere are mentioned Mr. C. E. L. Brown, M. Marcel Deprez, Von Dolivo Dobrowolsky, Dr. Edelmann (of Munich,) Prof. Ferraris (of Turin), Dr. O. Fröhlich (of Berlin), Prof. Eric Gerard, Prof. Von Helmholz, Dr. Kittler (of Darmstadt), Drs. F. and W. Kohlrausch, Prof. Mascart, Herr Schuckert, Herr Carl Siemens (of St. Petersburg), Herr W. von Siemens, and Herr Uppenborn.

THE TRANSMISSION OF POWER BY ALTERNATING CURRENTS DIFFERING IN PHASE (ROTARY CURRENTS.)*

BY VON DOLIVO-DOBROWOLSKY.

The development of the industries in general, and of the electrical industries in particular, is continually increasing the importance of the transmission of power by electricity. At the time of the Münich electrical exhibition, the experiments of Marcel Deprez were very warmly welcomed, and there was an impression at the time that great things might be expected of them. For several years, however, no progress in this branch was made, the cause being the low efficiency and insecurity of the dynamos of that date, but from 1886 to 1888 the so-called English school of electrical engineers made such improvements in dynamos as to render possible the transmission of power on a large scale. During this time the Oerlikon Maschinenfabrik did great service in this direction, but continuous currents, on account of the delicacy of the commutator and the difficulty of transformation, being little suited for distribution and transmission of power over long distances, the hopes of engineers have hitherto remained unfulfilled; the construction of a continuous current machine to supply energy at 10,000 to 20,000 volts to single motors and to lamps is at present almost an impossibility, and will certainly remain so.

* Extracted from the *Elektrotechnische Zeitschrift*

Digitized by Google

Although we do not wish to deny the many good qualities of the continuous current, we think the alternating current alone suited for the distribution of power on a large scale over long distances. But until recently there has been no practical alternating-current motor, and it is to this point that the attention of engineers and scientists has been directed. All their efforts produced no result until 1888, which must be looked upon as the year of the birth of the distribution of power by alternating currents. The discovery of Ferraris, and the investigations of Schallenberger and Tesla were published at this time, whilst many others were working on the use of alternating currents differing in phase, without, however, any practical result being reached. Tesla's motor, which attracted so much attention when it came out, does not seem to have fulfilled anticipations, as no commercial application of it has yet been made. As will be seen later, Tesla's arrangement with two quite independent currents, differing 90° in phase, possessed little advantage; its faults were avoided in the arrangements of other inventors, and motors with a larger number of alternating currents were simultaneously worked out by Bradley, Haselwander, Wenström, and the present writer.

Tesla's motor, as is well known, consists of a magnet ring carrying two sets of bobbins. These two sets are supplied by two alternating currents differing in phase by 90°. The result is a rotating magnetic field in the interior of the ring (a so-called "Ferraris," or rotating field), which accordingly acts almost exactly as if a constant magnetic field were mechanically revolved in it. On this principle extremely simple motors, without either sliding contacts or brushes, can be built. As a matter of fact, mistakes have often been made recently with regard to the Tesla motor. The following consideration will show that it cannot act in a particularly satisfactory manner. Each of the two currents displaced by a quarter phase exerts a magnetising force which at any moment

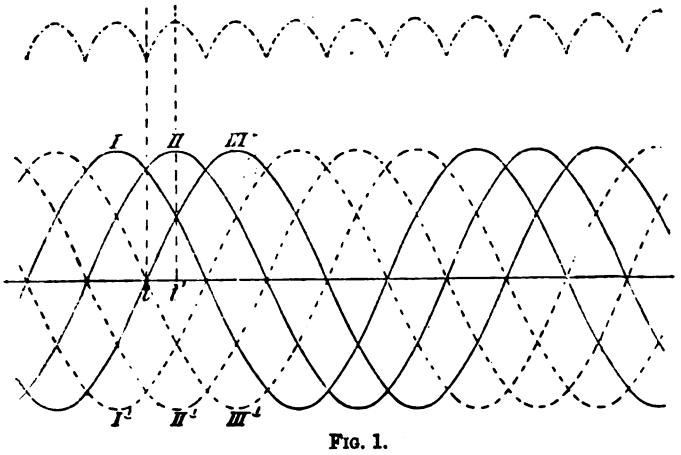

FIG. 1.

is equivalent to the product of the number of turns and the current strength at the moment. The total magnetising force exciting the motor magnet is equal to the sum of both sets of ampere turns, and is consequently also a function of the sum of the two currents. Now, in practice, this sum is never constant. It is true that in Ferrairs's arrangement the resultant force of the two sets of coils at right angles to one another on a mathematical magnetic pole must be considered constant, but this cannot be applied to material motors where the ordinary rules of electro-magnets come into force. The currents, being displaced by 90°, their sum varies between the limits i and $2\,i$ sin 45°, i being the maximum value of each current. When either current has this maximum value, the other is zero, and their sum is consequently equal to i. When the two currents are equal, as at the time t, each is equal to i sin 45°, and their sum is therefore 1·4 i. The total number of ampere turns, to which the excitation of the motor is due, therefore varies as much as 40 per cent. of its least value, so that the magnetic field of Tesla's motor is not merely rotating, but also pulsating to a very considerable extent. The action of the motor is accordingly far from being so simple as it at first sight appears. It is possible, with the help of Elihu Thomson's alternating motor, to consider the two properties of the field separately. The motor consists of a magnetic field due to an alternating current, and an armature, of which the windings form closed circuits. Like all synchronous alternating current motors, it must be brought up carefully to the proper number of revolutions per minute before the alternating current takes up the work. If overloaded, it comes to a sudden standstill, for the pulsations of the field only serve to turn the armature when it is going at a particular speed. If this is not reached they not only check, but absolutely stop rotation, because the currents induced in the closed circuit armature do not correspond properly in time and direction to the field, so that it is very difficult to start such an armature in an alternating field. Now, a Tesla motor, or, in general, a two-phase motor, as we have seen above, has a magnetic field which pulsates 40 per cent. in intensity, and it must, therefore, to a partial extent, possess the same properties as Thomson's motor: whenever Tesla's closed-circuit armature is not moving synchronously, the torque is only equivalent to the difference between the effect of its rotating field and the checking due to the pulsation of the magnetism. The motor, therefore, does not run well under load, and exhibits at full speed a tendency to synchronism up to a certain limit of load, beyond which its speed and torque rapidly diminish. The usefulness of the motor is, therefore, limited, and it can only be regarded as an improvement on the perfectly synchronous motor of Thomson, by reason of its power of starting under a heavy load when the circuit is closed.

A good motor, free from the faults accompanying synchronism, can only be produced on the principle of the rotary current by reducing the intensity of the pulsations of the magnetic field. The ideal field is absolutely constant, the lines of force rotating in exactly the same way as when a continuous current magnet is rotated. This ideal is approached by increasing the number of currents, of which the phases are made to follow one another. At the same time, it is not necessary to use very many currents. A glance at Fig. 1 will show, even in the case of three currents, the sum is sufficiently constant. At the time t, the sum is equal to 2 sin 60° × i = 1·732 i, i being the maximum value of each current. And at the time t_1, the sum is 2 sin 30° × i + i = 2 i. The pulsation of the field, which this variation of the sum of the currents involves, is, with three currents, therefore, only 15 per cent. instead of 40, as in Tesla's motor. The number of alternations being relatively small, the saturation of the iron can be carried up to a high degree without impairing the efficiency, so that, for a variation of 15 per cent. in the ampere turns, the total quantity of magnetism remains practically constant.

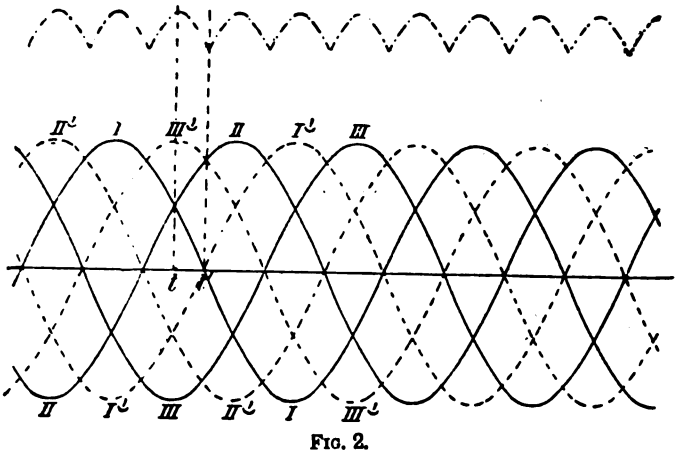

FIG. 2.

Ordinarily, the increased number of conducting wires would constitute an obstacle to the practical application of the transmission of three separate currents differing by 60° in phase. Even if it be granted that, owing to improvements in the dynamo, three currents could be conveyed by four conductors analogous to Tesla's three wires for conducting two currents, these four conductors would still be too costly. A simple arrangement allows the three currents to be conveyed by three conductors, and without using any more copper than that required for the Ferraris-Tesla device. This is made possible by supplying three currents differing by 120° instead of 60° in phase, and is effected by reversing the connections of the bobbin which supplies one current. To each of the circuits in the motor correspond at least two oppositely wound coils producing opposite poles, so that we may also add the curves obtained by reversing the signs. Fig. 1 thus becomes transformed to Fig. 2. This figure represents the three currents differing in phase by 120°, and is quite analogous to Fig. 1, in which the phase difference is 60°.

Considering Fig. 2 more closely we find that at the time t the sum of the currents I. and II. = 2 sin 30° × i, whilst III. = i, so that since sin 30° = 0·5, I. + II. = III. At the time t' again I. = 0, II. is proportional to sin 60° and III. to sin 120°, so that I. + II. = III. Generally, a similar relation holds good at any time, as may be seen from the fact that the currents are sinoidal. Each of the currents (or pressures) is equivalent and opposite to the sum of the other two, so that their algebraic sum is always equal to zero, whilst the sum of their absolute values, as above observed, varies between 2 i and 1·732 i. From the fact that the algebraic sum of the three currents or pressures at any moment is zero, it follows from Kirchhoff's laws that one current can be connected either in series with, or parallel to, the other two. This gives two methods of connecting, which are set forth diagrammatically in Figs. 3 and 4. We call the former arrangement the "open," the latter the "closed" connec-

Digitized by Google

tion. This connection renders possible the conveyance of the three currents through three conductors, in that the current flowing in one conductor finds its way back by the other two. A similar system can also naturally be employed in the case of more than three currents being used; it was independently and simultaneously found out by Bradley, Wenström, Haselwander, and the present writer.

In the course of the careful experiments carried out by the author with the Allgemeine Elektricitäts Gesellschaft in working out the details of the system there appeared many cogent reasons for abandoning this simple arrangement. Amongst these were the small output and consequent low efficiency, the heavy cost of dynamos and motors, the difficulty of regulating and measuring the currents in the three connected circuits, and of controlling them, &c.

The following system is now being generally applied by the Allgemeine Elektricitäts Gesellschaft. The dynamos supply several perfectly independent currents, usually six, although any number may be adopted. A large number of currents enables the dynamos to be used to the best advantage in that the whole circumference of the armature can be covered with active turns which, as is well known,

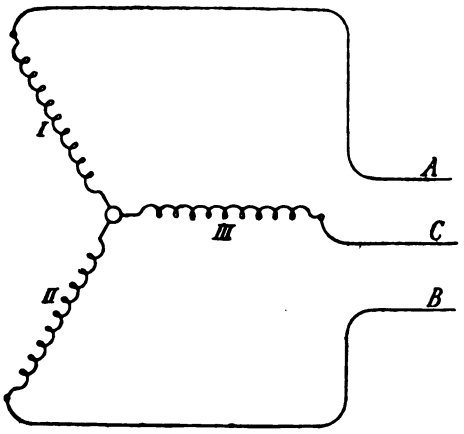

Fig. 3.

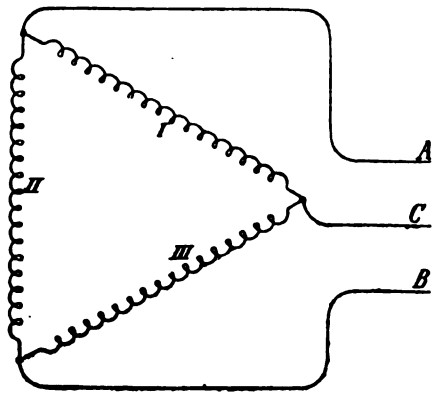

Fig. 4.

cannot be effected with ordinary alternators. An increase in the output in relation to size is also rendered possible from the fact that a multiple phase machine gives out energy continuously, whilst ordinary alternators only pulsate. The energy flowing in the conductors is also constant, since, as above pointed out, the arithmetical sum of the separate currents is practically constant, just as in the case of the continuous current. The distinct unconnected currents supplied by the machine are carried separately through switches, regulators, and measuring instruments, and then combined by suitable transformers into three connected currents differing by 120° in phase. These are conveyed wherever they are required, and finally again split up in order to be utilised. The transformer depends upon the rotation, by means of the rotary current, of a magnetic field inside a closed iron ring without poles, whilst the compound current supplied from the machine excites in the secondary coils similar current impulses following behind one another. The transformation corresponds to the action that takes place in a rotating current dynamo, except that in the transformer the field rotates about fixed coils, whilst in the dynamo the armature is mechanically rotated in a fixed field.

Since in the transformer three connected currents, differing by 120° in phase, have been produced, the idea will at once occur that the same loss will again take place as in the case of the currents directly connected. This is, however, not true. Certainly, in consequence of the connection, 15 per cent. loss in pressure takes place, and the transformation ratio is not equal to that between the number of turns, but it is only necessary to increase the number of turns in the secondary by 15 per cent. in order to fully utilise the primary currents. The efficiency of the transformer is consequently only very slightly affected. As a general rule the loss in transformation and the cost of transformers are not of great importance, since it is generally preferable to build machines for a relatively low voltage and to transform the energy to a high voltage before supplying it to the conducting wires. A dynamo for from 50 to 100 volts can be built so much more cheaply and safely that a transformer pays for itself, and the low pressure machine works so much more economically that the three or four per cent loss in the transformer is balanced. It is hardly necessary to point out that this mode of procedure is generally the only one applicable in the case of very high pressures exceeding 10,000 volts.

Fig. 5 shows a diagram of one of the numerous arrangements possible for a rotary current transformer, in which the six separate primary currents are transformed into three connected currents. The behaviour of the connected currents of the secondary winding is a reproduction of that of those in the separate primary circuits, so that the regulation of current and tension is perfectly simple. By the connection of the secondary currents we also secure the advantage that the long and, therefore, expensive conductors need only be three instead of four in number. At the second transformation at the receiving station it is preferable for the object of running large motors, just as for lamps, to resolve the combined currents again, for reasons similar to those which apply to dynamos.

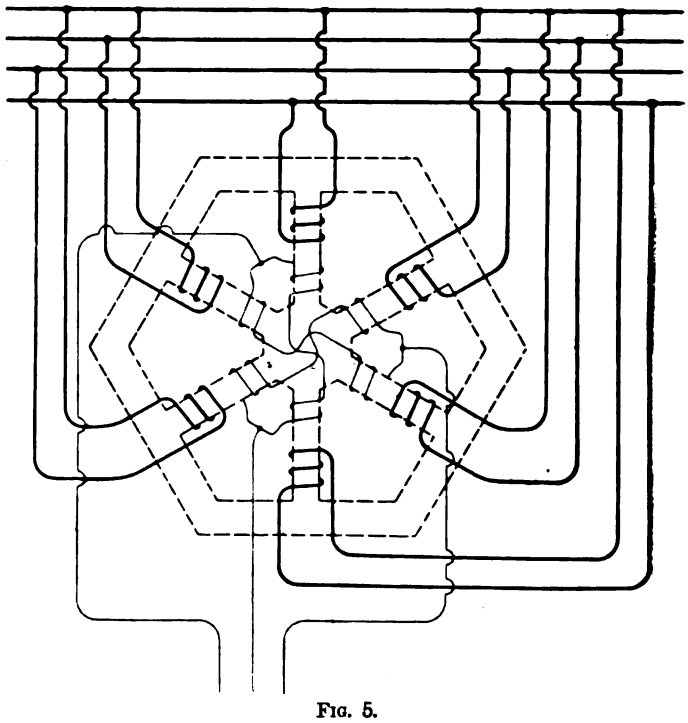

Fig. 5.

It will now be pointed out that the weight of the conductor required for equal energy is not greater for the three wires of the rotary current system than for the two wires of the ordinary system. In order to determine the conductor section for a combined rotary current, such as is used in transmitting power over a long distance, it is first of all necessary to obtain a clear idea as to the amount of energy conveyed. The solution must be obtained in the same way as in the case of an ordinary alternating current, and we therefore assume that there is no self-induction, and therefore no displacement of current with reference to electromotive force. If self-induction does exist the same modifications that occur with an alternating current also present themselves with a rotary current. Moreover, we will consider the case in which each pair of the three conductors is equally loaded since only the full normal load need be considered in determining the section of the conductor. Fig. 6 shows a conductor with a combined rotary current, the current strength being I and the pressure e. By I we mean either the maximum or the effective or the mean current strength, and not the momentary strength. The loading is effected by the three equal branches i_1, i_2, and i_3. The course of the current, as we have above proved, is always such that each current finds its way back by the other two conductors, and that the current maxima in the three conductors follow one another at intervals of 120°. I_1 is consequently split up between i_2 and i_3, I_2

Digitized by Google

between i_1 and i_3, &c., so that there is an interval of 60° between i_1 and i_2. Hence $I = 1{\cdot}732\ i$. From this we also see that the maxima of the current I do not coincide with those of i, but that the maximum of I_1 lies midway between those of i_2 and i_3, the resultant current I being 30° removed from the separate currents i.

From the above assumption, that the apparatus does not possess self-induction, no difference in phase takes place between the electromotive force and the current to which it gives rise, so that the current i appears simultaneously with the pressure e. On the other hand, between e and I there is a phase interval of 30°, since i and I differ from one another by this amount. In other words, there exists in combined three-phase currents a phase interval of 30° between the current in one main conductor and the pressure between the other two. The total energy is equal to $3\ i\ e$, that is, to three times the energy in each branch. If, now, we put for i its value $\frac{I}{2 \sin 60°}$, we get for the total energy $3\ i\ e$ $= 3\ e \frac{I}{2 \sin 60°} = 1{\cdot}732\ I\ e$; that is to say: If the combined rotary current carries in each of the three conductors an effective current strength I with the pressure e, the energy transmitted is $1{\cdot}732\ I\ e$. If, now, we wish to convey the same amount of energy with a continuous or alternating current, the effective strength thereof must be made equal to 1·732.I. But for equal lengths of conductor and equal loss of pressure the section must be taken proportional to the current strength, whence it follows that if in the case of a rotary current of strength, I, each of the three conductors has a section equal to q, for a continuous or alternating current two conductors each of section $1{\cdot}732\ q$ are necessary. Consequently the total section can be reduced by about 13 or 14 per cent. Also from the observations given above as to the proportion between the currents in the mains and the branch conductors, it will be seen that for each ampere in the three mains carrying the combined rotary current ·866 ampere are obtained in each of the branch wires, or that a rotating current of 1 ampere is resolved into three alternating currents of ·866 ampere and of the same pressure, so that 1 ampere of a rotatory current at 100 volts represents 173·2 watts. We repeat that these relations hold good only when—(1) an equal load is thrown on to each of the three branches; (2) the load is without self-induction; and (3) the measurements are taken by separate ammeters and voltmeters, and not by a wattmeter. In the latter case the product $I\ e$ will appear smaller, since, as mentioned above, a constant difference of phase of 30deg. exists between I and e.

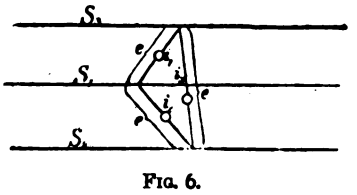

Fig. 6.

These conclusions have very little value in actual work, since, practically, the first of the three conditions never, or very seldom, holds good. Moreover, in the rotary current central station the currents are uncombined and independent, as above explained, so that the control of the loads can be very simply effected by the electrician in charge. The measurement of the consumption at the receiving station is also easy, the combined current being there resolved again into its components. The lamps are placed on two mains only, and are taken account of by simple recording apparatus, whilst the large motors are placed on separate circuits, and their consumption is measured by suitable wattmeters. For small motors supplied with the combined rotary current the measurement of one current is sufficient without any correction for the inequality in the separate circuits.

The electromotors, as above mentioned, are constructed upon the Ferraris-Tesla principle, that is to say, the different multiple phase currents produce a rotating magnetic field of nearly constant intensity, and this rotating field forces an armature with closed coils, or some similar arrangement to revolve with it. Different arrangements are adopted according to the special conditions and the size of the motors. The very small ones (up to ¼ H.P.) are constructed with a circular magnet concentric with the armature, having internal Pacinotti projections, the coils filling the space between the teeth. The armature consists of a massive iron cylinder, with numerous holes bored through it parallel to the axis; through these pass copper wires, connected at the extremities by means of two end plates, or rings, of high conductivity copper.

In another type of motor a transformer is employed fed by three wires carrying three combined high pressure rotary currents, and which supplies from its secondary double the number of currents of very low voltage, the phases of which follow close after one another. When a motor is not required to be built for specially high pressure, but it is to be worked by a low pressure current (say of 100 volts) such as is used in the mains of a town, it is advisable, especially for motors of over 1 H.P., to employ another type by which a transformation is avoided. In working out this third type of motor, the first aim was to attain a high efficiency, since in these cases the energy has to be paid for by the consumer, according to the reading of a wattmeter, and at a pretty high rate. The arrangement of this type is practically an inversion of the first. The magnet is placed inside, and rotates whilst the closed circuit armature is fixed.

We see, then, that the rotating current motors, so far as concerns their construction, are extremely simple; we will now show from some tests carried out that, as regards performance and economy they must be placed above the best direct current motors. Fig. 7 shows graphically the result of tests on a 2 H.P. motor of the type last described for 70 volts and 35 complete periods per second. The tests were carried much higher than the normal allowable load in order to determine the behaviour of the machine under excessive load and abnormal conditions. The weight of the motor was about 165 kilogrammes, and, from several trials, it appeared that a load of 2 H.P., after a long run, only heated it to a slight extent. In the interests of durability and safety this was fixed as the normal load. Since the motor can be allowed to run for a short time at double the load, it is clear that the limit taken is perfectly safe. From the weight and the curve of efficiency it appears that this load is by no means relatively low. From the curve in Fig. 7 we see that

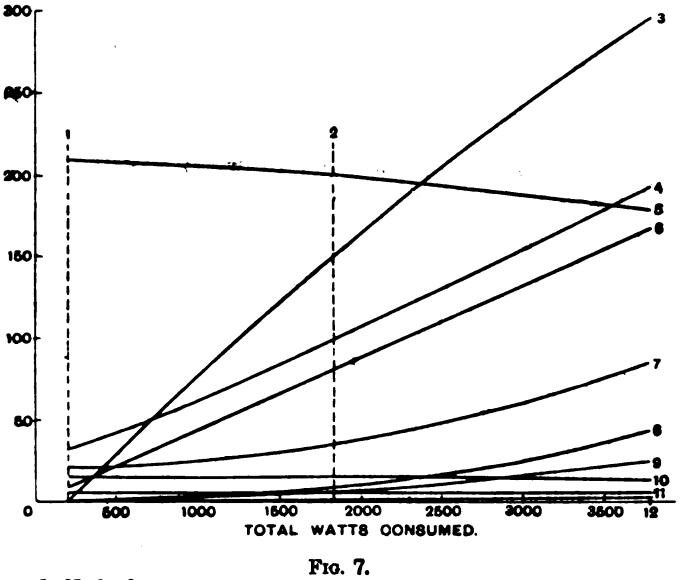

Fig. 7.

the motor is absolutely devoid of synchronism, the number of revolutions when running at no load being below that calculated from the number of alternations. Then between no load and the maximum, the number of revolutions only falls about 6 per cent., an amount which for a 2 H.P. motor is quite unimportant, and certainly below that which occurs in any direct current motor under similar circumstances. Although the speed falls off more quickly as the load is increased, it is noteworthy that at 100 per cent. overload the speed is still fairly high, and the property that alternating motors have of coming to rest when overloaded is quite done away with. From the same table we see that, starting from 205 watts, which are required when running light, the utilisable work rises nearly in proportion with the electrical energy consumed, certainly up to 3 H.P., from which point, perhaps, the proportion falls off. The output at the pulley is given in watts, in order to facilitate its comparison with the electrical values. The losses in the motor, as in every electrical machine are of three kinds. (1) Loss in the copper ($i^2 r$) in magnet and armature. (2) Magnetic losses—hysteresis and Foucault currents. (3) Mechanical losses—friction of air and bearings. All these losses in the motor are carefully

Digitized by Google

determined separately, and plotted out in Fig. 7 as functions of the watts consumed by the motor. We see from these curves that the loss in the copper rises pretty quickly as the load is increased; it is these losses which tend to make the curve of efficiency fall off with an increased load. The loss from air and bearing friction is approximately constant, and the slight inclination of the corresponding curve towards the axis of abscissæ is due to the fall in the number of revolutions. The hysteresis and Foucault currents in the iron of the magnet are also nearly constant, falling only slightly towards the end of the curve. Hysteresis in the fixed armature, on the contrary, continually increases, because the reversals of polarity in the armature, as already explained, depend upon the "slipping" of the motor, that is, to the difference between the number of revolutions of the motor and of the lines of force. The above losses are shown both added and separately in Fig. 7. The proportion between the available output and the watts consumed gives the total efficiency of the motor, and is plotted out in Fig. 8. The output in watts at the motor pulley are taken as abscissæ, and ordinates are drawn at the points corresponding to 1, 2, 3, and 4 H.P. We see from this curve that even at 1 H.P. (half load) the efficiency reaches 75 per cent., at normal load, 2 H.P., it is over 80, and reaches its maximum 81·4 per cent at about 2·3 H.P. From the flatness of the curve it is obvious that the economical regulation of the motor is very good, and that overloading, which is unavoidable in practice, and if it lasts only a short time does not damage the motor, has very little effect on its efficiency. A comparison with direct current motors shows clearly that rotary current motors of the same size are a distinct advance in point of capacity and efficiency. It may further be pointed out that rotary current motors can start from any position with considerable force, so that no friction or other coupling is necessary.

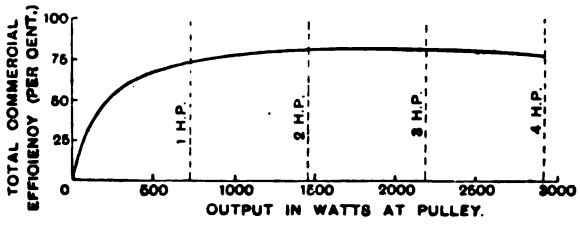

FIG. 8.

The 2 H.P. motor above referred to was tested as to its capability of starting under a load in the following way:—It was coupled direct to a direct current dynamo, the field of which was independently excited, so that a load existed as soon as motion commenced. The armature of the dynamo was connected to a circuit, the resistance of which was such that the motor at full speed was carrying more than double load. The rotary current was then suddenly thrown on, and starting was found only to take up two to three seconds. The reversal of the direction of rotation of the motor with the dynamo coupled thereto (presenting a considerable amount of inertia) was effected in about four seconds. If the load was entirely taken off, the starting of the motor by itself required no appreciable time (without resistances), and no noise was caused, it being hardly possible to hear the motor when running, even when quite close to it.

In conclusion, we will point out a very valuable property of rotary current motors, as compared with many other alternating motors. When loaded there is only a very small difference in phase between current and electromotive force, so that the proportion between the watts actually consumed in work and the apparent watts is nearly equal to unity; the conductors also do not have to be made of any larger section than corresponds to the same capacity for direct currents. From the current in the magnet (Fig. 7), which holds for one of the three circuits in the motor, and from the working pressure, we get at normal load for the apparent watts the value

$$3\ (70\ \text{volts} \times 9{\cdot}9\ \text{amp.}) = 2{,}079\ \text{watts.}$$

The actual consumption, as the curve shows, amounted to 1,830 watts, and the fraction of the apparent value is ·88. The difference in phase between current and electromotive force which, when running light, amounts to 72°, at 2 H.P. load is 28°, and at 3 H.P. 22°. Whether this proportion appears as favourable in larger motors cannot be definitely assorted, the necessary measurements not having been taken.

The chief aim of the present article has been to draw attention to the rotary current as a new means of transmitting power, and to give a general idea of the system; many points will, therefore, seem to want further explanation, and the author intends to publish a series of independent articles on the details. He also hopes that the Lauffen-Frankfort installation will afford a large number of electricians the opportunity of inspecting the system at work

ALTERNATE CURRENT MOTORS.*

BY E. HOSPITALIER.

Alternate current electric distribution, in America at least, is comparable in size and extent with continuous current distribution, and they would be much more extensive if we knew how to conveniently utilise electric energy when distributed by means of alternate currents in connection with electro-chemical operations. It would increase the number of such plants, also, if we could store the energy supplied by alternate currents, and if we could easily transform alternate current electric energy into mechanical work; for such applications the continuous current motor has remained up to the present superior to the alternate current motor. The drawbacks that I have enumerated are, however, compensated for by several advantages, viz., the simplicity of construction and cheapness of alternators, the easy production and transformation of the highest potentials (it being difficult to obtain more than 3,000 volts with continuous currents), simplicity and ease of insulation, simplicity and ease of transformation by means of inert apparatus, containing no moving parts, and having as high an efficiency as 95 per cent.

If the use of alternate currents for electro-chemical and storage purposes has scarcely yet been admitted (the partial solutions of the problem being still of an experimental character), the same cannot be said of alternate current motors. The various principles put forth, and the types based upon them, are already so numerous as to render necessary the summary classification given in the table below:—

A.—CONSTANT FIELD OR SYNCHRONOUS MOTORS.

SEPARATELY EXCITED	*Magnets.*—Magneto-Alternators.
	Electro-Magnets.—Dynamo-Alternators.
SELF-EXCITED	*"Redressed" Current.*—Zipernowsky.

B.—ALTERNATE FIELD MOTORS.

Series-Wound Dynamo	Continuous current motor, with laminated field-magnets.
Shunt-wound Dynamo	Continuous current motor, with laminated field-magnet.
Electro-dynamic Motors	Elihu Thomson meter.
Partially "Redressed" Field	Mordey.
Closed Circuit Armature	Elihu Thomson.

C.—ROTARY FIELD MOTORS.

Ordinary or Single-Circuit Alternators		Ferraris.
		Tesla.
		Shallenberger.
		Hutin and Leblanc.
Multiple Phase Alternators.	*Three wires and two currents.*	Ferraris.
		Tesla.
		Borel.
	Three wires and three currents.	Dolivo-Dobrowolsky.
		Brown.
		Haselwander.
		Bradley.
		Wenström.

An alternate-current motor does not differ essentially in principle from a continuous-current motor. The same two essential parts are always to be found; the magnetic field, or inducing magnet, and an induced system rotating with reference to the other. While, however, the magnetic field of a continuous-current motor is always constant, that of an alternate-current motor is constant, alternating, or rotary, according to circumstances.

Constant Field Motors.—This, the oldest type of motor experimented with, is based upon the principle of the reversibility of alternators. The alternate current is sent through the armature coils, which rotate in a constant magnetic field, produced by a permanent magnet or by an electro-magnet. The simplest is that formed by a Siemens double T coil revolving between the poles of a permanent magnet, or of an electro-magnet excited from an external source. In this motor, if it has been brought up to the speed corresponding to the frequency of the alternate current supplied (for example 50 revolutions per second if the frequency of the alternator is 50), it revolves in synchronism with the alternator, following all its variations of speed unless a load of more than a certain amount is suddenly applied to it. If this is done the motor is thrown out of synchronism and immediately stops. The theory of these machines was developed, in 1884, by Dr. Hopkinson. The necessity for synchronism at the start, and for an external source of electric energy for exciting the field magnet when large motors are wanted, and the necessity for running at a rigorously constant speed, have prevented these motors from receiving many commercial applications. Zipernowsky caused the two most serious of these inconveniences to disappear by rendering the motors self-exciting, the exciting current being derived from a shunt circuit containing a "redressing" commutator. A motor of this kind will start by itself when unloaded, and quickly attains its

* Paper read before the Société Française de Physique.

Digitized by Google

normal speed, which it keeps perfectly in spite of sudden variations of load. The efficiency of these motors is very satisfactory, attaining 80 per cent. in 4-kilowatt machines. In spite of—or, more exactly, owing to—the synchronism necessary for the running of these machines, a few of them have been used for the purpose of long distance transmission of power.

Alternate Field Motors.—Any continuous current dynamo supplied with alternate currents will start and continue revolving with considerable mechanical effort. A machine of this kind is comparable to an electro-dynamometer, the torque of which always remains the same in spite of the alternations in the direction of the current. A motor of this kind, however, possesses numerous and serious defects. The rapid alternations of current develop Foucault currents in the field-magnets, greatly reducing the efficiency of the motor, unless the precaution has been taken to laminate the cores. Moreover, the high inductance of the motor reduces the current, and consequently the output, of a motor of given dimensions. For these reasons motors of this type are but little employed except where small power is wanted, as in the case of motors driving small domestic ventilating fans, taking one to two amperes at a pressure of 50 volts, such as are in actual use in America. The exciting circuits of these motors are either arranged in shunt or series. If we suppress the iron in the field-magnets and in the armature, we obtain an electro-dynamic motor of small output, the motive couple of which is at any instant proportional to the currents traversing the armature and field coils. The energy meter of Prof. Elihu Thomson comes under the heading of an electro-dynamic motor. To avoid losses by Foucault currents and hysteresis due to the rapid reversals of magnetism of the field-magnets of motors of this type, Mordey has suggested passing the alternate current through a commutator on the shaft of the motor. On starting, the commutator has no effect, but as the speed increases the current becomes more and more "redressed;" that is to say, the losses caused by reversals of magnetism are reduced and the efficiency improved.

Closed circuit motors also come under the head of motors with alternating fields. The electro-dynamic repulsion experiments of Professor Elihu Thomson have shown that a closed circuit placed in an alternating field tends to move so as to render the coefficient of mutual induction a minimum; in other words, it tends to reduce to a minimum the flux threading the coils. If we place a series of movable coils revolving round a common axis in an alternating field, and arrange the brushes so that each coil is successively short circuited at the moment when the flux threading it is a maximum, and open circuited when the flux is zero, and so on, there will be exerted on each coil a certain torque, which, owing to the multiplicity of coils, will be sensibly constant. In motors of this type there is no connection between the field and the armature. The field coils are closed on the supply wires and the motor coils are closed on themselves. Such a motor can easily be realised by means of a small Gramme or Rechniewsky two-pole machine, if we take care to give the brushes a forward lead of about 45deg. Alternate field motors are but little used, and no experiments as to their efficiency have as yet been published.

Rotary Field Motors.—Professor Ferraris, in March, 1888, was the first to make public the principle of these alternate current motors, the development of which now seems likely to cause a revolution both in long distance transmission work and in the distribution of electric energy for small motors. The following is the principle established by Ferraris:—When two alternate currents of the same period, lagging one behind the other by a quarter period, are passed through two circuits arranged at right angles, the result is a constant rotary magnetic field revolving at a constant speed, making one complete revolution per period. If now a closed magnetic circuit is placed in this rotary field, it will be the seat of induced currents, and these induced currents will tend to turn the induced circuit in the same direction as the rotary field. With the exception of the method of producing the rotary field, the rotation thus obtained is identical with that of the chemical "Avago" experiment, known under the name of "Magnetism of Rotation."

One might state with accuracy that the rotary field motor works in virtue of the Foucault currents, of which it is the seat. These Foucault currents would be zero if the circuit was stationary with regard to the field, that is to say, if the circuit revolved at the same speed as the field; and it is to fulfil this condition of relative immovability that the circuit turns within in the field, and in the same direction. In short, the circuit runs after the field.

Although of relatively recent invention, rotary field motors are already very numerous, and varied in principle and arrangement. They are distinguished amongst themselves chiefly by the mode of producing the rotary field, and by the generator which supplies current to the motor. I will now examine the ordinary alternate current motors, and the motors supplied with multiple phase currents.

There are several means of obtaining an ordinary alternate current, two alternate currents lagging a quarter phase behind each other, and capable, therefore, of producing a rotary field. Ferraris employed two circuits—one supplied with current direct from the alternator, the other connected to the secondary of a transformer, the primary of which was connected to the main leads of the alternator. Tesla employs two circuits arranged in shunt, and possessing widely different time-constants. Shallenberger employed a closed circuit armature placed obliquely with reference to the primary circuit supplied with current from the alternator, and the reactions of the primary circuit and of the armature circuit producing a rotary field. In the Hutin and Leblanc motor the rotary field is produced by two sets of coils connected in parallel, a condenser being interposed in one of the circuits. In this way the quarter phase lag necessary for the production of a rotary field is easily obtained.

The above solutions of the problem are suitable in the case of distribution to comparatively small motors. For the purpose of long distance transmission on a considerable scale, it is preferable to have recourse to special generators, no longer producing ordinary alternate currents, but several alternate currents lagging a fraction of a phase one behind the other, that is to say, "polyphasal" alternate currents. We may either employ two currents and four wires, or only three wires, using one as a common return. Devices of this kind have been brought out by Ferraris and Tesla. Being obliged to use three wires some have preferred to employ three currents of equal periodicity, but lagging one behind the other one-third of a period. By taking advantage of the employment of three currents retarded in this way, we can make the algebraical sum of the currents at any instant zero, and one of the three wires can always serve as a return to the currents traversing the other two. Such is the principle of the motors supplied with "polyphasal" currents, devised less than two years ago by Dolivo-Dobrowolsky, Haselwander, Bradley, and Wenström. A 300 H.P. transmission of power plant of this kind, due to Brown of Oerlikon, is now in process of erection between Frankfort and Lauffen.

This rapid enumeration of the methods actually employed or investigated for the convenient transformation of the energy of alternate currents for mechanical purposes shows that we may consider the problem as solved. It will doubtless be the same soon as regards the utilisation of alternate currents for electro-chemical and storage purposes. Alternating currents will then assume a commercial importance superior to that of continuous currents, and we shall witness a new evolution of electric systems, while awaiting that which the employment of alternating currents of high frequency will some day give rise to.

THE ELECTRIC TRANSMISSION OF POWER.*

BY GISBERT KAPP.

LECTURE II.—*Fundamental Principles.*

(Continued from page 366.)

What we generally desire to get in practice is a constant speed of the motor, whatever may be the mechanical power taken out of it at any moment. This condition is the same as that required from a good steam engine or other well-governed prime mover. The construction of the motor to comply with this requirement depends, of course, on the condition of supply. We can imagine a large variety of cases; but, from a practical point of view, I need only consider two, namely, supply at constant pressure such as we get, or ought to get, from mains connected with a central electric light station, and supply of current at constant or variable pressure from a generator erected specially for the purpose, the regulation of current and pressure being automatic. The latter case is that more particularly met with in long distance transmission of large powers, the former is a case referring rather to the distribution of small parcels of power over short distances from a central station. I will take this first.

We have, then, these supply conditions—pressure at the terminals of the motor constant, current variable according to the call for power. Let (in the diagram Fig. 4) the curve F represent the characteristic of magnetisation of an electromotor, that is, a curve obtained by plotting ampere-turns of exciting power on the horizontal and total field strength (denoted in the formulæ by F or Z) on the vertical. If the motor is series-wound, you see that the larger the current the stronger will be its field, and by referring to the E.M.F. formula you will find that if the speed is to remain constant the counter E.M.F. must increase in the same ratio as the field strength increases. But the counter E.M.F. must, under all circumstances, be smaller than the supply E.M.F., by just the amount required to overcome the resistance of the circuit through the motor, and this difference is, of course, proportional to the current. To satisfy the supply condition the counter E.M.F. of the motor ought to slightly decrease as the load, and with it the current, increases, then the speed will keep constant. But this is exactly

* Cantor Lectures delivered before the Society of Arts, February, 1891

Digitized by Google

the opposite of what the motor requires. Say the machine is running at a certain speed, and giving out a certain amount of mechanical power. Now increase the load. The immediate consequence will be that the speed is slightly decreased, the counter E.M.F. is slightly decreased, and the current is increased. This will immediately strengthen the field, and thus raise the counter E.M.F. again; this will check the current, produce a further drop in speed, and so the reaction will go on until a new stable condition of working is reached at a larger current and lower speed. If we take the load off the same reaction takes place, only in the opposite sense, and the speed may become dangerously high. What I have here described happens, of course, only if the machine is worked on the rising part of the E.M.F. characteristic E, the part which we would naturally select for economical working. If we over-excite the field magnets, that is, if we employ a great deal more field wire than necessary, then we can work the machine on the drooping part of the characteristic shown by a dotted line in the diagram, and obtain approximately constant speed between certain limits, but the machine will still be liable to race as soon as we throw the load off completely. We thus find that a series-wound motor is certainly not suitable for our purpose.

Let us now inquire whether we shall be any better off with a shunt-wound motor. The field excitation in such a machine does not depend on the current flowing through the armature as in a series machine, but it is simply the result of the terminal pressure; in other words, whatever current may be required by the armature for giving power, can be and is, in fact, supplied by the source of current, without in any way affecting the field excitation. If the terminal pressure varies, the excitation and the field strength must also vary, but a variation in the working current will not directly influence the field strength. It will, however, indirectly influence it by reason of a subsidiary effect technically termed "armature reaction," and this I shall touch upon shortly. For the present we neglect it, and assume that the curve F correctly represents

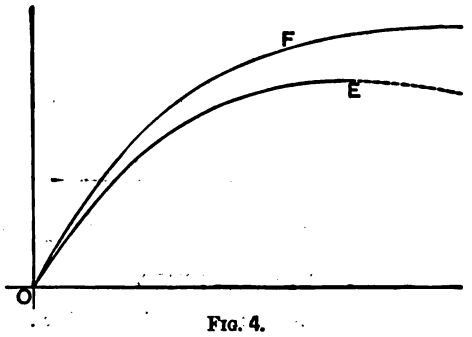

FIG. 4.

the field strength as a function of the terminal pressure. In machines having wrought-iron magnets the first part of this curve is almost a straight line, and in this region the field strength is consequently very nearly in direct proportion to the terminal E.M.F. To work the motor at this part of its curve all we have to do is to supply it with current at a pressure sensibly lower than that for which it is designed. In good machines the resistance of the armature is very low, so that only a few per cent. of the voltage supplied is lost in resistance, even when the maximum current flows through the armature. If, therefore, we work the motor considerably under its power, the armature loss will be almost negligible, that is to say, the counter E.M.F. will be very nearly equal to the supply E.M.F. Now, if you look at the formula for E.M.F., you find that on the left you have a value very nearly equal to the supply E.M.F., and on the right you have a constant multiplied with the product—field strength and speed. But the field strength under our special conditions of working is proportional to the supply E.M.F., and as you thus have the supply E.M.F. on both sides of the equation, it cancels out, and you find that the speed, multiplied by a constant, is equal to unity. This, of course, holds good for any supply E.M.F. within the straight part of the curve; and we find, therefore, that the speed has a definite value which is independent of the supply E.M.F. We have here arrived at a very remarkable result. It is this, that if you work a shunt-motor underloaded and at a lower pressure than it is designed for, you may vary this pressure within certain limits without either altering the speed or the power given out.

As, however, the motor must be large in proportion to its work, the practical use of this remarkable property of shunt-motors is limited. What users of these machines want to do is not to get little power out of them, but to get as much power as possible, and, in many cases, more than was intended by the designer. Let us, then, see how we stand in the matter of speed and power regulation when we work the machine throughout the whole range of output for which it is designed. First, as to speed. Let us assume that the machine is working at a certain speed giving off a definite amount of power, and suppose we wish to increase the speed. How shall we do it? The E.M.F. formula tells us. You see that field strength and speed occur on the same side of the equation. This means that the one can only be increased at the expense of the other. If we want the machine to run faster we must weaken its field, if we want it to run slower we must strengthen it. The variation of field strength is most conveniently brought about by a variable resistance in the magnet circuit. I have such a resistance in the shunt circuit of the machine before you, and can show you, by an experiment, this method of regulating the speed.

In this experiment we have altered both the speed and power, because, by running faster, we have obtained more current from the second machine and a brighter light in the lamp. Let us now see whether it is possible to keep the speed constant, and yet vary the power. Bearing in mind that the dynamo is a reversible machine, and drawing a parallel between a shunt-dynamo and a shunt-motor, we conclude that there should be no difficulty in doing this. The fact that a shunt-motor is an almost self-regulating machine has been first pointed out by Mr. Mordey in an article which appeared in January, 1886, in the *Philosophical Magazine*. Mr. Mordey's reasoning was somewhat as follows:—We know that a shunt-dynamo will, if driven at a constant speed, give an almost constant terminal pressure, no matter how the current may vary. Consequently, a shunt-motor, if supplied with current at constant pressure, will run at an almost constant speed, no matter how the load may vary. On testing his theoretical deduction by actual experiment, Mr. Mordey was able to completely verify it. In one set of experiments the supply current was kept at 140 volts, and the load on the motor was varied from 1·8 to 16·3 H.P., yet the speed only varied by 3 per cent.; and a similar result was obtained with the same machine at a supply pressure of 100 volts. Mr. Mordey stated in his Paper that the magnetic distortion of the field was *nil*, or, as we might also term it, that the armature reaction was negligible. It is, however, easy

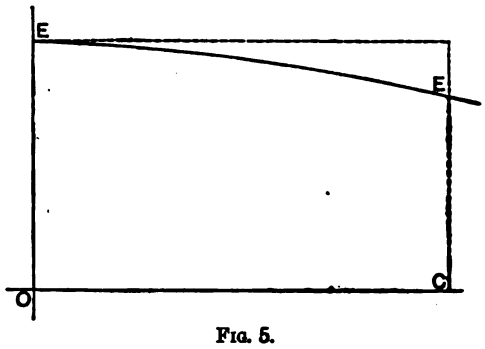

FIG. 5.

to see that, even if the armature reaction is sensible, we can yet obtain very fair regulation, provided we take care to have in the armature circuit such a resistance that the voltage loss due to the resistance is about equal to that due to armature reaction.

To explain this I must first say a few words about armature reaction, a phenomenon which may, perhaps, not be familiar to all of you. The current flowing through the armature transforms it into an electro-magnet, which, to a certain extent, opposes the flow of magnetic lines emanating from the field magnets. This is the case both in dynamos and motors, though not quite to the same extent. The larger the current the larger is the opposition which the armature offers to the field magnets; and it is the field strength which remains, after making allowance for this opposing magnetic force, which is productive of electromotive force. To calculate correctly the counter E.M.F. of a shunt-motor, we must, therefore, not assume the field strength in our E.M.F. equation to be constant, as I have done hitherto; but we must assume that it decreases slightly as the armature current increases. Graphically, this is represented in Fig. 5, where the current flowing through the armature is measured on the horizontal O C, and the field strength is represented by the inclined full line above. If there were no armature reaction, the field strength would be given by the dotted horizontal line. If the speed is to remain constant, the counter E.M.F. must be proportional to the field strength; and, by suitably altering the scale (with which we measure the ordinates in the diagram), we can take the top line to represent counter E.M.F. I have accordingly marked it E E.

The vertical distance, O E, represents now the supply E.M.F.; and, when the motor is running light, this is, of course, equal to the counter E.M.F. Now, let a load be thrown on, causing a considerable increase of current. The counter E.M.F. need now not be quite so large as before, since part of the supply E.M.F. has been already absorbed by the resistance of the armature circuit, and the counter E.M.F. need only balance the remainder. We find, thus, that the supply condition of constant voltage requires the counter E.M.F. to become lower, as the power demanded from the

Digitized by Google

motor increases. At the same time, the working condition of constant speed can only be attained by a lowering of the counter E.M.F. as the current increases; and it is, therefore, perfectly obvious that, if the lowering of the counter E.M.F., as determined by either condition, is the same, we must have constant speed at variable power—that is, a self-regulating motor. Generally, the line E E in the diagram representing counter E.M.F. is not quite straight, but slightly curved, presenting the concave side to the axis of abscissæ; whilst the line representing resistance loss through armature is, of course, quite straight. If we so design the machine as to get exactly the same speed when running quite light and fully loaded, the speed will be slightly less at half-load, but the difference can only be very small. I am able to show you this property of the shunt-motor to be almost perfectly self-regulating, by means of the apparatus here before you.

Thus you see that the shunt-motor is an excellent machine for keeping the speed constant when worked on a constant-pressure circuit. The only drawback to its employment is, that the resistance must be inserted into the armature circuit at starting; but this may be done automatically, by placing the resistance permanently in circuit, and causing it to be short circuited by means of a centrifugal regulator fixed to the armature shaft, and so arranged that when the speed has attained a certain value the balls fly out and close a switch. Such an automatic device is also of value in case the motor should be overloaded. If this should happen the speed will drop, and the resistance will be automatically re-inserted, keeping the current within safe limits. By these means a customer of an electric light company is prevented from taking from the mains more current than he has contracted for.

Before leaving the subject of speed regulation on constant pressure circuits, I must briefly allude to a system in use on electric tramways. Motors for tram-cars are not required to run at a constant speed, but they are required to have a wide range of torque.

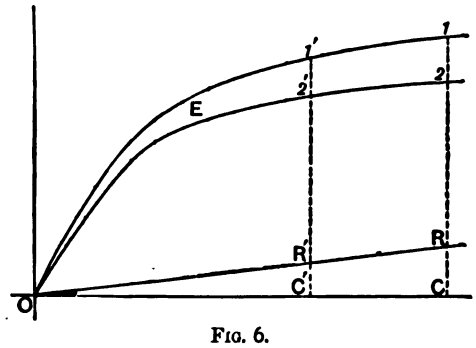

Fig. 6.

At starting, or when running uphill, the speed may be low, but the static effort must be great. These motors are, therefore, generally series-wound, and provision is made by means of a compound switch for inserting a larger or smaller number of field magnet coils, so as to vary the field strength according to requirements. The arrangement of the motors under the floor of the car is shown in the diagrams on the wall, which represent respectively the cars of Mr. Reckenzaun, the Electrical Engineering Company, and the General Electric Power and Traction Company, but time will not permit of my going into the details of the various designs.

When current is supplied to the motor not from a general system of mains, but from a special generator, serving no other purpose, the regulation of speed and power can be effected equally well by series, compound, or shunt machines. As regards the latter, I need not go into details, as this case is really included in the case of supply at constant pressure, which I have already fully treated. After what I have said about this case, you will also readily see that compound wound motors with the main coils demagnetising are equivalent to shunt-motors with large armature reaction, and that, in fact, a shunt-motor with very small armature reaction, such, for instance, as a multipolar machine, may be made self-regulating by the addition of demagnetising main coils on the field magnets. I shall later on give you details of a large transmission plant carried out on these lines, and need, therefore, not go further into the subject now. There remains, then, only the plain series motor to be considered.

In this case both the generating and the receiving dynamo are series-wound, and it is easy to see that by suitably designing these machines we can bring it about that the motor will run at a constant speed under varying loads if the generator is kept running at a constant speed at all times. Let the two curves in Fig. 6 represent the E M.F. characteristics of the two machines, the upper curve referring to the generator and the lower to the motor. These curves give the useful E.M.F. after deducting armature reaction, and refer, of course, to constant speed in each case. The current flowing through the circuit is that which we obtain by dividing the difference between the ordinates of the two curves by the total resistance. The resistance is, of course, a constant, and the curve representing current and difference of E.M.F. is, therefore, a straight line, O R in the diagram. The vertical length, C R, gives the voltage loss with a current, O C, due to resistance, and this must be equal to the voltage difference, 1, 2, between the curves. This determines, therefore, the speed of the motor for that particular current. Suppose the lower curve is the E.M.F. characteristic for that particular speed. Now, let us throw some of the load off, then the current will assume a smaller value, say O C'. The voltage loss is now C' R', and the voltage difference 1' 2'. If the E.M.F. characteristic fits this new working condition, then 1' 2' must be equal to C' R', and the speed will remain the same as before. We thus find that if we so design the machines that the difference between their E.M.F. characteristics at any working point is equal to the voltage loss by resistance, we obtain a perfectly self-regulating system of power transmission. Most of the transmissions now at work have been designed by taking advantage of this very valuable quality of series machines, but I must state at once that, in actual practice, the case is not quite so simple as I have here represented it. One of the difficulties met with is that we cannot always get the two characteristics to fit each other exactly over the whole range of output; another difficulty arises from there being generally a slight difference between the ascending and descending characteristices; but the most serious obstacle to quick and perfect regulation is the self-induction of the field magnets, especially if the machines are large. The self-induction prevents the rapid response of one machine to the other which is required to make the regulation absolutely perfect. A sudden change of load cannot be followed immediately by a corresponding change in the power supplied to the motor, as time is required by the magnets to settle down into the new working condition; and during the transitory period, which may last many seconds, there is a surging of power to and fro which creates fluctuation of speed. To mitigate this evil, Herr Dobrovolsky, of the Berlin Electric Company, has devised a plan by which a kind of electrical damper is applied to the generator in the shape of a non-inductive high resistance placed across the terminals of the magnet coils as a shunt, and left there permanently. Any abnormal wave of E.M.F. which might otherwise disturb the working of the motor or endanger the insulation of either machine spends itself in heating this resistance, and the disturbance quickly subsides.

The Line.

I pass now to the consideration of the line, a subject of great importance, especially in long distance transmission, since in these cases the cost of the line forms a very large item in the total cost of plant. You are all familiar with Sir William Thomson's law for greatest economy in conductors. Briefly, the reasoning on which this law has been developed is as follows:—The annual cost of power delivered is made up of two items. First, the cost of the power only, and, secondly, the interest on the capital outlay. The cost of power includes that amount which is wasted in heating the conductor. If I, therefore, wish to work with the greatest economy, the sum of annual interest on the capital outlay and cost of power wasted must be a minimum; and this condition is attained when the two are equal. Profs. Ayrton and Perry were the first to question the practical applicability of this law. In a Paper read by them before the Institution of Electrical Engineers, in March, 1888, they showed that, under certain conditions, better economy can be obtained by departing from, instead of following, Sir William Thomson's law. I do not propose to give you quotations from their Paper, which is highly mathematical, but I will endeavour to put the subject before you in a different way, requiring only very little mathematical treatment.

First of all, let us see, in a general way, what Sir William Thomson's law really means. It supposes that the annual electrical horse-power has a definite value at any place reached by the conductor. This is generally assumed for the distributing system as carried out from central stations. Whether a customer lives 100 yards or 500 yards from a central station, the company charges him the same for the current. But the assumption is not, strictly speaking, correct. To see this, let us suppose that the cost to the company of putting an annual horse-power into their mains is £20, and they get £30 for every annual horse-power taken by the customer. Now, if I lose 1 H.P., shall I be right in writing off this loss at £20? Clearly not; for if I had not lost this particular horse-power, I might have sold it for £30. But there is another way of looking at this. You might say that the £10 difference between the cost and selling price of power represents profit and interest of plant and mains, and that, therefore, the lost power should be debited at net cost. To this I reply, that my object is not to put power into the mains, but to take power out, or, rather, enable my customers to take power out, for which they will pay me; and so we might keep arguing the question, without ever coming to a definite understanding. Now, if we cannot settle such a simple problem by common-sense reasoning, there must be something wrong in our premises; and in this case, it is not difficult to see where the hitch is. It is in the

Digitized by Google

assumption that the power has a constant value. In reality, this is never the case. If it were the case—that is to say, if one horse-power had the same value at the motor end as it has at the generator end of the line—it would be perfectly useless to establish a transmission plant; it would be like carrying coals from Cardiff to Newcastle. It is only because the power has a great value at the motor end of the line, and a small value at the generator end, that it will pay us to lay out capital in plant, and incur the risk of working it.

Most Economical Current for Electric Power Transmission.

D ..... Distance in miles.
a ..... Section of conductor in square inches.
E ..... Terminal volts at generator.
e ..... Terminal volts at motor.
$H P_g$ ..... B.H.P. required to drive generator.
$H P_m$ ..... B.H.P. obtained from motor.
c ..... Current in amperes.
Efficiency of generator 90 per cent.; efficiency of motor 90 per cent.
g ..... Cost in £ per electrical H.P. output of generator.
m ..... Cost in £ per B.H.P. output of motor, including regulating gear.
$G = 9 g H P g$... Cost in £ of generator.
$M = m H P_m$ ... Cost in £ of motor and regulating gear.
$t = 18{\cdot}2 D a$ ..... Weight in tons of copper in line.
K .. .. Cost in £ per ton of copper, including labour in erection.
s ..... Cost in £ of supports of line per mile run.
p ..... Cost in £ of one annual B.H.P. absorbed by generator.
q ..... Per-centage for interest and depreciation on the whole plant.

$$\text{Capital outlay} = g\,E\,c/746 + m\,H\,P_m + D\,s + \frac{1{\cdot}6\,K\,D^2\,c^2}{E\,c - 830\,H\,P_m} = A.$$

$$\text{Annual cost per B.H.P. delivered} = q\,A/H\,P_m + p\,H\,P_g/H\,P_m.$$

$$\text{Put } B = E\,p/670 + q\,E\,g/746.$$

$\gamma = 830\,H\,P_m/E$, the current which would be required if the line had no resistance,

and $\beta = \gamma^2 \dfrac{E\,B}{1{\cdot}6\,q\,K\,D^2 + E\,B}$; then the most economical current at the given voltage E is

$$c = \gamma\left(1 + \sqrt{1 - \frac{\beta}{\gamma^2}}\right)$$

$$c = \gamma\left(1 + \sqrt{\frac{1{\cdot}6\,q\,K\,D^2}{1{\cdot}6\,q\,K\,D^2 + B\,E}}\right).$$

For very long distances the term under the square root approaches unity, and the most economical current the value 2γ; from which it follows that under no circumstances will it be economical to lose more than half the total power in the line.

The correct way of treating this problem is, therefore, to take into account the cost of the power, both at the generating and at the receiving station. We must, further, take into account not only the interest and depreciation of the line, but also the interest and depreciation of the machinery at either end; and, in estimating these items, we must know at what voltage the plant is to work, and what total power is required; for the prime cost per horse-power depends very materially on the total power and voltage. To make this clear: if I want to reduce the capital outlay on the line, I must work at high voltage, and with a large energy loss. This means that I must put down a larger generator than would otherwise be required, and, moreover, one that gives a high-pressure current. It is thus quite possible that what I save in the line I shall have to expend at the generating station, to say nothing of the increased charge for waste power, and the greater liability to have a breakdown, owing to high voltage.

You see this problem is a very complicated one; and Thomson's law, which says nothing about voltage or cost of machines, will not fit it. It is, however, possible to amend this law, so as to obtain at least an approximate solution. The premises on which the formula has been deduced are as follows:—

Conditions given.—Annual value of brake horse-power at generating station; voltage at generator terminals; brake horse-power required at motor end; distance of transmission; cost per horse-power of machines and regulating appliances at the given output, and voltage; cost of conductor, per ton of copper erected, interest, and depreciation of whole plant.

Data required.—Working current, brake horse-power at generating station, mechanical efficiency, voltage at motor, total capital outlay per brake horse-power delivered, and cost of annual brake horse-power.

The efficiency of each machine is assumed to be 90 per cent. The formula gives only the current, but the other data can be found by very simple calculations, which need no explanation. The cost of supports for the line per mile, whether overhead or underground, can be taken as constant, that is, not depending on the exact current within the limits, which can easily be foreseen in each case; and it therefore does not enter into the formula for the current. Interest and depreciation I have taken the same for all parts of the plant, so as to avoid too great a complication of the formula. If you now work out by the aid of the current formula the same transmission problem for different voltages, you will find that there is one particular voltage for which the annual cost of the brake horse-power delivered at the motor end of the line is a minimum; and, provided this voltage is within reasonable limits, it ought to be adopted. When making such calculations, you will find that the greater the cost of power at the generating station, the higher is the most economical voltage, this voltage also, of course, increasing with the distance.

Each case must be worked out with due regard to local conditions, and nothing in the shape of cut and dried rules or figures can make this work superfluous. On the other hand, it is very desirable to collect information as to the cost of works which have actually been carried out, and by the liberality of Mr. Brown, the engineer to the Oerlikon Works, Switzerland, I am able to place before you some figures of this kind which are contained in the following table. The figures give the whole capital outlay for the electrical parts of some of the power transmissions erected by this firm:—

Cost of Transmission of Power Plant.

Distance in miles.	H.P. Delivered.	Speed of Machines.	Cost in £.			Total Cost.*	Cost per H.P
			Gen.	Mot.	Line.		
1·870	85	450	640	560	440	£1,880	£22·2

* This includes regulating apparatus, instruments, posts, insulators, lightning arresters, erection, and supervision.

LEGAL INTELLIGENCE.

Crompton and Co. v. Phillips.

In the Court of Appeal, on Friday last week, the case of Crompton and Co. v. Phillips came before Lord Justices Lindley, Bowen, and Kay, in the form of an appeal by the defendants from the judgment entered in the Court below in favour of the plaintiffs.

Mr. Finlay, Q.C., and Mr. Wallace appeared for the defendant in support of the appeal, while Mr. Moulton, Q.C., and Mr. Graham opposed it on behalf of the plaintiffs.

Mr. FINLAY, in support of the appeal, said he now asked that judgment should be entered for the defendant, or a new trial granted, on the ground that the verdict of the jury was against the weight of evidence. The action was brought by Messrs. Crompton and Co., the well-known electrical engineers, against Mr. Phillips, manufacturer of wires used for electrical purposes, to recover damages for an alleged failure to perform a contract for the supply of certain insulated wire. The defendant manufactured three qualities of insulated wire, which were known as B, C, and D qualities, B being the lowest quality, C the medium, and D the best. On June 4, 1889, the plaintiffs wrote to the defendant, stating that they required a certain quantity of insulated wire for the purpose of supplying the borough of Chelmsford with the electric light, and asking him to quote special terms for B and C qualities. The defendant replied to that letter on the following day, giving the quotations asked for, and the plaintiffs eventually ordered a large quantity of C quality. Having put up nearly 60,000 yards of this wire in the open air at Chelmsford, the plaintiffs complained of the quality of the wire supplied. They removed some of the wire, but left standing about 35,000 yards. The case was tried before Mr. Justice Day and a special jury, with the result that the jury found a verdict for the plaintiffs, and added that the plaintiffs had been guilty of contributory negligence in not examining the wire, which was an exceptionally bad article. Mr. Justice Day entered judgment for the plaintiffs, leaving the question of damages to be decided by two experts. The defendant's position at the trial was this, that the wire in question was perfectly good so long as it was used for the purpose for which it was manufactured and ought to be employed. It was perfectly suitable for use indoors, but they did not make it for use out of doors, and the whole of the loss which the plaintiffs said they had sus-

Digitized by Google

tained was due to their using such a cheap wire out of doors. That was what the jury meant by their verdict.

The case was then adjourned.

TUESDAY, AUGUST 4TH.

Mr. WALLACE continued the arguments in support of the appeal. He submitted that C wire ought to be tested in the dry.

Mr. MOULTON said Mr. Finlay had admitted that the proper way to test the wire was to put it in water.

Mr. WALLACE remarked that that was the proper test for guaranteed wire.

LORD JUSTICE KAY: Then your argument comes to this—that C wire is not to be tested at all?

Mr. WALLACE: I say it is not to be tested by putting it in water. Continuing, the learned counsel said Mr. Crompton had admitted that the use of the wire at Chelmsford was an experiment which he had made for the first time. The alleged faults in the wire were not defects, they were characteristics of the wire.

LORD JUSTICE KAY: That is going rather too far. Is it a characteristic to have a crack every five yards?

Mr. WALLACE: No. That was not the case with this wire. The plaintiffs accepted the wire, used it, and made no complaint until the Board of Trade informed them that it was not thick enough for the voltage. He submitted that the verdict of the jury was not justified by the evidence, and that it ought to be reversed.

LORD JUSTICE LINDLEY said the Court would like to hear Mr. Moulton in reference to the one point. They did not feel that the learned judge, notwithstanding his great efforts, succeeded in keeping the minds of the jurors upon the only point they had to consider, namely, whether the wire supplied was merchantable in quality. If Mr. Moulton satisfied them upon that particular point they would not trouble him further.

Mr. MOULTON maintained that the judge made the point clear to the jury, and that the jury found for the plaintiffs upon the evidence. The opinion which the jury added to their verdict meant that if the plaintiffs had examined the wire before they used it they would have rejected it at once, and thereby saved the expense of putting it up and taking it down again. That was a perfectly intelligible finding, because the plaintiffs claimed the costs to which they had been put in fixing and removing the wire.

The case was again adjourned.

WEDNESDAY, AUGUST 5TH.

Mr. MOULTON, continuing his arguments, contended that the wire supplied was not merchantable insulated wire. It was unfair to Messrs. Crompton to suggest that they had purchased a low priced article. Mr. Crompton stated, at the trial, that the wire in question was a high priced wire. Mr. Justice Day would not allow the plaintiffs to give evidence on the question of price, remarking that if they had paid a high price for a bad article that was their look out.

LORD JUSTICE LINDLEY, in delivering judgment, said that the question raised was an important one, not only to the parties but also to persons interested in electric lighting. The order for the wire was contained in three letters, from which it was obvious that plaintiffs knew defendants sold B and C qualities of wire. Mr. Justice Day, at the trial, directed the jury, from the beginning to the end, that the only question they had to consider was whether the C quality wire supplied by defendant to plaintiffs was a merchantable quality wire, telling them there was no guarantee in the letters. It was admitted that the distinctive marks of this wire were not known in the trade, but were terms used by defendant to denote a particular article. The point at issue, then, was reduced to this—did the C quality wire mean covered wire or did it mean insulated wire. If it meant covered the defendant had performed his contract, if insulated he had not. Now, it was said that the failure of the wire arose entirely from its having been applied by the plaintiffs to a purpose for which it was not intended and was unfitted. That was true, but how came it to be so applied? Plaintiffs assumed, and had a right to assume, that C wire was of merchantable quality; in other words, was insulated as distinguished from merely covered wire. The verdict had been rightly described as a curious one, and more than one interpretation had been placed on it in the arguments. What he (his Lordship) thought it meant was this: "We (the jury) are not going to give you (plaintiffs) the cost of putting up and taking down wire which you ought to have examined before erecting it." But this did not carry the case further for the defendant, and it appeared to him that, guided by the rules which ordinarily applied to these cases, it was impossible to say that this verdict was against the weight of evidence, that this Court should interfere with it. The misunderstanding which arose he attributed entirely to the ambiguity of the letters on which the contract was based. The appeal, he thought, should be dismissed.

LORD JUSTICE BOWEN said he was entirely of the same opinion.

LORD JUSTICE KAY said he was also entirely of the same opinion. The card containing samples of the three kinds of wire described C quality as being wire insulated by being covered with vulcanized india rubber. During the progress of the work at Chelmsford the plaintiffs were anxious to know what was the resistance of the insulation, and the defendant replied that the approximate resistance was 250 megohms per knot. Subsequently, when the wire was tested by being placed in water, the insulation was found to be very defective. In the case of some of the specimens the electric current escaped altogether. Agreeing with his learned brother (Lord Justice Lindley) that the question for the jury was whether the wire sold and purchased as insulated wire was, in fact, insulated wire, he was of opinion that there was evidence upon which the jury might well find that, whatever else "C" quality meant, it meant, at least, this—that the wire was insulated, and that the wire supplied to the plaintiffs was either not insulated at all, or was so very imperfectly insulated that it did not deserve the name of insulated wire. There was certainly ample evidence to justify the finding that the wire supplied was not the wire the plaintiffs contracted to buy, and, that being so, it was quite impossible for the Court to disturb the verdict.

Mr. MOULTON asked that the appeal should be dismissed, with costs.

LORD JUSTICE LINDLEY said the appeal would be dismissed, with costs.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 25, 1891.

The Brush Accumulator Patent.—The protracted patent litigation between Mr. Brush and the Electrical Accumulator Company has just been terminated by the decision of Judge Coxe emphatically in favour of the former. This practically gives Mr. Brush and his assigns the monopoly of the lead accumulator in this country if they choose to assume it. From the nature of Judge Coxe's decision last year in the suit between the Julien and Brush interests the result of the present action was to be anticipated. What its effect will be it is as yet too early to state. The Julien Company, sole licensee, under the Brush patents, certainly holds the key to the situation. Apropos to this the United Electric Traction Company will resume, it is stated, the operation of its accumulator cars on the Fourth Avenue road in this city, which have been discontinued for some months.

The Edison Lamp Patent.—Everyone is waiting with interest the action of the Board of Directors of the Edison General Electric Company, in the matter of incandescent lamps. Judge Wallace has just granted a stay in the matter of the injunction ordered in the decree accompanying his opinion, and the case will go to the Circuit Court of Appeals, probably immediately after the opening of its session next October. It will probably be the first case on the docket of this tribunal. Meanwhile, the United States Electric Lighting Company has given bonds in $50,000 to cover the alleged infringement during the period that elapses before the decision is heard under the appeal. In granting the stay Judge Wallace frankly stated that there was a fair chance that his decision might be reversed in the Upper Court, and said, in substance, that the claims of the Edison patent were in such loose terms that there was little wonder that they had been infringed. In the meantime, the incandescent lamp manufacturers are awaiting further action on the part of the Edison Company. Those most interested are the small makers. It is rumoured that the Thomson-Houston Company has entered into some sort of an agreement with the Edison Company in this matter, and the rumour is strengthened by the fact that some of the Thomson-Houston officials have expressed themselves as rather satisfied than otherwise with the nature of the decision.

Forthcoming Meeting of the National Electric Light Association at Montreal.—Preparations for the semi-annual meeting of the National Electric Light Association in Montreal are rapidly progressing. The exhibits promise to be very fine, and a very large attendance is expected. Some radical changes were made in the administration of the association at its last meeting, and the healthy effect of these has already made itself very manifest.

Work in the Edison Laboratory.—At Mr. Edison's laboratory some important work is going on, but the details have thus far been successfully kept from the inquiring public. It is known that the alternating current system is nearing its finished form, in which it will be put upon the market. Apart from this, Mr. Edison's own time is largely taken up with his mining work, the applications of the magnetic separator in particular; so far he has obtained excellent results.

BOOKS, &c., RECEIVED.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all, Vol. I., 20; Vol. II., 18), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

ELECTRIC LIGHTING OF THE CENTRAL STATION, MANCHESTER.—The Cheshire Lines Committee have recently decided to erect an installation for the complete lighting of their central station, Manchester, and have placed the order for the whole of the plant with Messrs. Mather and Platt, of the Salford Iron Works. The plant will consist of incandescent lamps for the refreshment rooms, ticket offices and waiting rooms, and of arc lights for the platforms. The plant is to be in duplicate throughout, and will consist of compound engines, "Edison-Hopkinson" dynamos for the incandescent lighting, and "Manchester" dynamos for the arc lighting.

CHANGES OF ADDRESS.—Owing to the increase in their London business, Messrs. Walter T. Glover and Co. have removed from 10, Hatton-garden, to larger and more commodious offices at Albany Buildings, 39, Victoria-street, Westminster, where are situate the new offices of Mr. Henry Edmunds. Considerable alterations and extensions having been made in their works at Manchester, Messrs. Glover and Co. are now prepared to give prompt delivery from stock of wires and cables for electrical purposes, in vulcanised, pure india-rubber, and gutta percha insulations; silk and cotton covering, and their patent braiding; as well as armoured and lead-covered cables in all sizes, concentric cables, and their patent anti induction and other telephone cables.

———. The Electrical Accessories Company (Limited) notify that their London office has been removed from Victoria-street to 5, Macclesfield-street, Shaftesbury-avenue, W.C., where larger and more convenient premises will enable them to keep a stock of all their well-known specialities, as well as a good selection of brackets, standards, and electroliers of all styles.

DISSOLUTIONS OF PARTNERSHIP.—Anders and Elliot, electrical engineers and telephone manufacturers, 10, Bush-lane, Cannon-street, London, E.C. February 7, 1889. Debts by C. H. Elliot. ——Poland and Childs, trading as Thurkle and Co., electrical and pneumatic engineers, 22, Denmark-street, Soho, London, W. June 5, 1891. Debts by H. E. Childs.

BANKRUPTCY PROCEEDINGS.—A receiving order has been issued in the estate of Montagu James Scott, trading as Montagu J. Scott and Co., electrical engineers and contractors, 11, South Molton-street, and 134, Regent-street, London, S.W.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

June 30, 1891.

11,134. C. A. FAURE. London. Improvements in apparatus for the electrolysis of aluminium.

11,144. H. VAN HOEVENBERGH. London. Improvements in printing telegraphs.

11,145. D. H. BATES and H VAN HOEVENBERGH. London. Improvements in and connected with printing telegraph instruments.

11,149. E. GUITTON. London. A multiple filament electric incandescent lamp. (A. Collet, France).

July 1, 1891.

11,157. J. RADCLIFFE and J. E. SPAGNOLETTI. London. Improvements in transmitters and receivers for telephones.

COMPANIES' MEETINGS & REPORTS.

Anglo-American Telegraph Company (Limited).

The ordinary general half-yearly meeting of the proprietors of the Anglo-American Telegraph Company (Limited) was held at Winchester House, 50, Old Broad-street, on the 31st ult., under the presidency of the Most. Hon. The Marquis of Tweeddale.

The Secretary (Mr. T. H. Wells) read the notice calling the meeting and the minutes of the last general meeting.

The CHAIRMAN: Gentlemen, I have now to ask you to adopt the report and the accounts, which have been in your hands some days, and which, I presume, you will take as read. The traffic receipts, amounting to £136,483 for the past half-year, show a decrease of £8,432 as compared with those of the corresponding period of last year. The whole amount available for dividend is less by £14,517, and is made up as follows:—Traffic receipts, to which I have referred, £8,432 less; on account of the charter of the "Minia" £3,340 less; interest on deposit account, &c., £629 less, and the balance brought forward £1,403 less; while the balance on account of the increase of expenses is unfavourable to the extent of £713. These items make up the total of £14,517. The dividend of 12s. per cent. which we are only able to pay is not a little disappointing to us, of course, but I do not think anyone will be surprised at this result who has kept his eyes open to the state of affairs, more especially of the commercial world, during the period under review. Not only has our income been adversely affected by the stagnation of business

Digitized by Google

following on the financial difficulties of last autumn, but in other ways our receipts have been reduced. For instance, owing to the interruption on the West Coast of South America, our traffic has been reduced to the extent of £10,000. I am happy to say that the interruption which existed so long is now removed, and our traffic in that quarter has resumed its normal condition. I only wish I could add that the depression in commercial circles had disappeared also. Still I think there is no reason to question that it will disappear in the course of time—not a very long time, I hope—and then our traffic will again recover its usual proportion. At any rate, Gentlemen, of this I am quite satisfied—that we have not suffered in any degree more than our competitors in the Atlantic. Nor, I think, can the reduced receipts be ascribed to any want of activity on our part in securing traffic. The report has told you that we have established new offices in several commercial centres. We have also provided a through wire from Paris to Brest and Havre, and have thus placed ourselves on an equality with our competitors in that country. Canvassing both at home and abroad has been pursued with great energy, and, I am glad to say, with corresponding successful results. I have the returns here which show what has been accomplished, and I observe that in one country, Belgium, our increase for the six months, compared with 1890, is about double, and in France about 25 per cent. Then at Southampton and other places the increase is very considerable. These increases are prineipally due to greater activity on the part of those who are looking after and collecting traffic for us. I daresay there are some persons who may remember the criticisms that were passed on our Company at our last meeting by one of our largest shareholders and customers. He complained that our lines were subject to interruptions in the winter which greatly interfered with his business. Well, I am happy to say that our friends of the Western Union Company have shown themselves alive to the necessity and importance of placing our communications under their control in a far more satisfactory condition. I have a letter here, the whole of which I shall not read, but I may read a few lines of it. It is a letter from General Eckert, who is the able manager of the Western Union in New York, and he says: "I have no hesitation in assuring you that even with a repetition of that experience (namely, the unparalleled bad weather of last winter), the precautions we have taken, and, I may add, without regard to cost, will prevent any appreciable delay in the business on the other side." In addition to that, your Directors have determined to take steps to connect Sydney, Cape Brèton, and Canso, Nova Scotia, by cable, and in this way we shall have direct communication by submarine cable between England and France and New York, which we have never yet had since our Company was established. I think that if Mr. Leon, the critic to whom I have referred, and whom I am glad to say is now a Member of Parliament, has the time to cast his eye over the report of our proceedings to-day, he will be glad to learn that his criticisms have borne fruit in the way I have just described. Gentlemen, the additional facilities thus given to the telegraphing public have not been provided without some increase of expenses, but our policy has been—and I trust it ever will be—to render our service as efficient as possible, not only with respect to speed (I doubt if we could do better in that respect than we are now doing) but with regard to freedom from interruptions and, above all, with respect to accuracy. I may mention that particular attention has, during the past year, been devoted to this matter, and I am pleased to say with very good results. Our cables are in good order generally, the only exception, indeed, being a short line known as the North Placentia cable, which has given us a great deal of trouble, and which will require some additional cable in order to make it as efficient as it should be, but I hope that by the time I address you again, this defect will be entirely removed. The accounts call for no particular comment, because I have already referred to the increased expenditure under the heads of B and C, and have explained that it was almost exclusively due to the improved facilities I have described. The renewal fund has reached the handsome figure of £990,000 in round figures, and it is, at current prices, worth about £29,000 more. It may interest you to know that during the last four and a-half years, we have charged the renewal fund with repairs and renewals about £120,000, being at the rate of about £27,000 a year. Our income from the renewal fund is about £32,000, so that for these years past we have been adding to the renewal fund at the rate of £5,000 a year. I do not think there is any other point upon which I need speak at any great length except with respect to the interesting question of the French cable, the Pouyer-Quertier cable, and as there may be some shareholders present who are not acquainted with the history of that matter I have drawn up a very brief memorandum showing exactly what has taken place from the beginning. If you will allow me to read it, it will not take more than a moment or two, and it will show you what the position of the case is at present. On December 30, 1886, M. Granet, Minister of Posts and Telegraphs, wrote to the French Company to the effect that by amalgamating its interests with foreign companies it had departed from the terms of the concession, and should take steps for observing the same. The next day the French Company denounced the agreements on the ground that the Minister's letter was an order obliging them to do so; whereupon proceedings were commenced by us in the Tribunal of Commerce. On January 9, 1888, that Court had decided that the French Company must resume the performance of the agreements under a penalty of 5,000 francs per day for every day's delay until the expiration of one month, and adjudged a considerable sum to be paid to this Company by way of damages already incurred. The French Company appealed from this judgment, and the Court of Appeal, on April 24, 1888, suspended judgment until competent authority had declared whether the Company had correctly interpreted M. Granet's letter. This question of interpretation was submitted in the first instance to the Council of the Prefecture of the Seine, which, on the 19th March, 1889, declared that M. Granet's letter had been rightly interpreted by the French Company. This decision was reviewed by the Council of State on the 1st May last, which set aside the order of the Court of Prefecture of the Seine, and determined that the letter in question had not the effect of an order compelling the French Company to break the contracts, but that it only amounted to an invitation to the French Company to take immediate steps to put itself right according to the conditions of its concession. Since the date of that judgment a correspondence has taken place between the French Company and its Government, from which it appears that the present Government would not sanction the joint-purse agreements. The case will now go back to the Court of Appeal, which will decide, and I hope finally, the amount of damages to which this Company is entitled through the unjustifiable conduct of the French Company, and we shall await the decision with great interest. I do not think you would expect me to express any opinion on the subject. There is no doubt that a gross breach of agreements was committed, but whether the French Court will see fit to give us considerable damages on that account or not, I shall not venture to predict. I think I have touched on every important matter which has arisen during the half-year, and I can only express a hope that when we meet again six months hence the prevailing depression in commercial circles, upon which our fortunes so much depend, will have disappeared, so that we shall be in a position to present to you a more satisfactory report than it has been in our power to do to-day. With these observations I beg to move the following resolution:—

"That the Report of the Directors and the accompanying Statement of Accounts to the 30th June, 1891, submitted to this meeting be, and the same are hereby, received and adopted."

The DEPUTY-CHAIRMAN (Mr. Francis A. Bevan) seconded the motion.

Mr. THOMAS SMITH (York) proposed an amendment, contending that the expenses in connection with the new offices which had been opened should not have been charged to revenue account. He wished to know what proportion of the loss of £8,432 in the traffics had occurred in the first three months in the year, as the Directors made this decrease an excuse for the paltry reduction in the dividends paid in May of 1s. per cent. on the ordinary, and 2s. per cent. on the preferred stocks.

The CHAIRMAN pointed out that he had stated that £10,000 had been lost through the Chilian interruptions.

Mr. SMITH, continuing, stated that the reductions which he had mentioned that had been made in the dividends compared with those paid on the 1st of May, had caused the market value of the Company's stocks to fall by between 3 per cent. and 4 per cent., amounting in gross to over £200,000. The Chairman had said that they had only been adding £5,000 a year to the renewal fund, but this was not correct. Whenever there was any increase in the traffic it was always added to the renewal fund. He maintained that the Directors were much to blame for reducing the dividends.

The CHAIRMAN: We can only pay what we have.

Mr. SMITH complained that charges had been made against the revenue account which should have been debited to the renewal fund, for the work which had necessitated these expenses was new, and was, therefore, he maintained, a capital charge.

The CHAIRMAN: Rent is payable out of revenue.

Mr. SMITH: You say you have put a special wire down which has been conceded by the French Government. The Directors had shown a great want of consideration to the shareholders' interests. There were, he said, many reasons why the Directors should see that their stocks were held in proper esteem on the market. He estimated the market value of the renewal fund at £1,050,000.

The CHAIRMAN said that the Directors estimated the value of the investments forming the renewal fund at £29,000 beyond their cost price.

Mr. SMITH said that he had had careful financial assistance in making his calculations. It was neither reasonable nor fair, he contended, that the cost of new offices should be charged to revenue. They were told that the renewal fund was required for new cables, and that their own were old and worn out; but it was stated in the report that their cables and land lines were in good working order. They knew, too, that wherever there was a fault it could be repaired, no matter the depth at which the cable lay. He suggested that 3½ per cent. should be the minimum dividend upon the ordinary stock this year. This would give the preference stock its full dividend and 1 per cent. to the deferred stock. He moved, as an amendment, that this dividend should be paid, and that, if need be, the renewal fund should be used for the purpose.

The CHAIRMAN, in answer to a question, stated that the amendment was not in order. The present was an interim dividend.

Mr. SMITH said that he would leave out of his amendment the recommendation as to dividend, and would move that the report be not adopted.

Mr. BRANDON seconded the motion, complaining that the deferred stockholders had received no dividend for seven years.

Mr. WREFORD also opposed the adoption of the report. They had, he said, been promised a dividend on the deferred stock whenever the renewal fund was worth more than £1,000,000.

Mr. JACKSON complained of the increase of the expenses under Abstract B—the expenses at the London office. Although the receipts had been £8,000 less, these expenses had been £1,208 more than they were in the December half-year. The expenses at the stations had increased by £1,689 over those of the December half-year, but this was reasonable, considering the new stations. He thought it was humiliating, with all the experience which this Company had had, that they should be beaten by their youngest competitor. He thought the Directors showed a recklessness as to the dividend which they paid. Lord Monck, who was for many years their Chairman, had led them to believe more than once that with liquid assets of £1,000,000 the interest of the renewal fund should be devoted to increasing the paltry dividends which the Directors, after so many years' work and experience, were able to offer them. For years 40 per cent. of their capital—the deferred stock—had received no dividend.

Digitized by Google

Mr. GRIGGS said he could endorse what Mr. Jackson had said, that Lord Monck stated that when the renewal fund reached £1,000,000 the deferred stockholders should be taken into consideration.

The CHAIRMAN: I will now reply to the remarks and questions that have been put. Mr. Smith asked what proportion of the decrease in the traffic occurred during the first three months of this year. It is not very easy to give that information at this moment, but if he calls at the offices, Mr. Weaver will, no doubt, give him that information. He has announced his reason for rejecting the report upon certain grounds. One is that the cost of the new offices should have been taken from the renewal fund. Surely, the rent of offices is an item that can only be debited to maintenance? I think our auditors—who, by the way, are appointed by the shareholders for their protection—would at once point out the impropriety of debiting to capital what is a revenue charge. I presume that the auditors are here, and if they express an adverse opinion on that point I should be surprised. Another reason for Mr. Smith's opposition is that the full 3 per cent. dividend should be paid, which I connect with the remark about the renewal fund. Dividends should only be paid out of our net receipts, and that raises the question of the renewal fund.

Mr. SMITH: Has not the renewal fund been taken from the receipts?

The CHAIRMAN: Yes, but will you allow me to continue? Let me repeat what I said at the last meeting as to the the renewal fund, and I believe those remarks were received with satisfaction by the large majority of all who were present. I may say that the only complaint that I have received is one from a proprietor at a distance, who, in a letter, considered that I had hinted at the possibility of appropriating a portion of the renewal fund, or rather the interest on the renewal fund to dividend. That is the only complaint I have had upon the report. Now, gentlemen, this is what I said at our meeting in January:—"It is a very delicate subject, and involves a question of dealing with the renewal fund. It has always been recognised that £1,000,000 was the very least we should have at our credit, having regard to the age and condition of our cables, and the necessity some day or other of renewing them. At the same time if we were to go on laying by as much as we have done during this last year, I have no doubt the Directors would then take into consideration the possibility of placing less to the renewal fund. This last year we added £27,894 out of the interest, which amounted to about £31,500. Now, if we can go on at that rate for a year or two more, I have no doubt the matter would be open to consideration. Beyond that it is impossible for me to go, and even that I am saying as my own personal opinion." I have nothing whatever to add to those words. I believe that what was laid down there is the correct policy, and the policy which will commend itself not only to the preferred shareholders but also to the deferred shareholders, who have just as much interest in the proper maintenance of our cables in the Atlantic. Mr. Smith said that it cannot be true that the cables are old and worn out. Does he mean to say that our cables are going to "live" for ever? One of them was laid in 1869. Is not that old?

Mr. SMITH: It can be renewed. We have proved over and over again that our cables can be renewed.

The CHAIRMAN: The oldest of our cables was laid in 1869, the next in 1873, the next in 1874, and the youngest was laid in 1880. I say, in view of that and our experience of the Atlantic, that we are bound to keep a very handsome reserve in order to be quite able at any time to maintain our four cables in the Atlantic, to say nothing of our many small cables on the other side connecting with the land. Mr. Smith is a man of such knowledge and intelligence that it is almost incredible he should put forward the idea that a particular dividend should be paid notwithstanding the revenue we receive. Then, he complained of the fall in the market price of our stock; but I am not aware that our stock has fallen so very much. I do not think that it has fallen as much as many of the great railway stocks. As my friend Sir John Pender said, not long ago, what is remarkable about these investments in cable companies is the small fall—the slight depreciation—that has taken place. That is what is remarkable to me—not that our stock should have fallen from the highest point ever reached in recent times.

Mr. SMITH stated that the preferred stock had fallen 5 per cent.

Mr. WREFORD: And your deferred stock was 36, and is now 11.

The CHAIRMAN: Mr. Smith calculates our renewal fund to be of the market value of £1,050,000. We have taken the middle prices, and we make the rise in value of the investments to be £29,000, so that there is a difference between our calculation and Mr. Smith's of about £30,000. It would, be idle to suppose that we could realise our renewal fund in these days at even that middle price. I cannot think that the criticisms of Mr. Smith justify the rejection of our report. The reduction in our receipts is in proportion to the reduction in the receipts of the other Companies—and I believe our diminution is rather less. I think we might take some credit for what has been done in view of the figures that I have given to you. With reference to the expenses at the head office, Mr. Jackson complained that, under Abstract B, they are £1,200 more than last year, but I find on looking at the accounts that the net increase in the expenses under Abstract B, compared with the corresponding half-year in 1890, is only £140.

Mr. JACKSON observed that the total amount of the expenses under Abstract B last half-year was £5,807, while in the present half-year the amount was £7,015, or the difference which he had mentioned.

The CHAIRMAN: I have the exact figures before me, and they show that under Abstract B the net increase is £140. The increase under Abstract C is £1,766, but that is due to the increase in salaries and wages, maintenance of land lines and repairs and renewals of buildings; and I believe that the meeting generally will agree that the whole of these charges should be put to revenue.

Mr. JACKSON repeated that the total of the expenses under abstract B for the half-year to the 31st of December last was £5,807, whereas this half-year, to the 30th of June, the total was £7,015.

The CHAIRMAN: But you must compare the two corresponding half-years. Then you complained of the success of the Commercial Cable Company. Well, our duty is to do our best to reduce their success as much as possible, and that is what we are trying to do, and I think we have done something towards it this half-year. Mr. Jackson also noticed that there is a considerable credit balance not invested. That is always the case at the end of a half-year, but the money will be invested, of course, when realised.

Mr. JACKSON: I am satisfied that we are in the best hands.

The CHAIRMAN: I will not say more about the opinion expressed by Viscount Monck, further than that I am quite sure he is in accord with me and the Directors with reference to the absolute necessity of having not less than the sum I have mentioned at the credit of our renewal fund. I think Mr. Smith will admit that he has not made a very strong case, to say the least of it, against us, and I would ask him to withdraw his opposition.

Mr. SMITH regretted he could not do so.

The CHAIRMAN: Then you will vote against the resolution.

Mr. SMITH: I have moved that the report be not adopted, and that has been seconded by Mr. Brandon.

The CHAIRMAN: That is not an amendment.

Mr. SMITH: You may take it as you like, but that is what I have moved.

The CHAIRMAN then put the resolution in the usual way, and declared it carried by a majority.

Mr. SMITH: By what majority?

The CHAIRMAN: By a considerable majority.

Mr. BRANDON: I doubt very much if there was a majority.

The CHAIRMAN: The report was adopted by a substantial majority. The numbers were 13 to 6. That constitutes the business of the meeting.

Mr. FRY expressed his sympathy with some of the remarks which had been made, and "a sort of regret" that there had been no indication from the Chairman that the Directors had in view any policy that would benefit the proprietors. He proposed a vote of thanks to the Chairman.

Mr. JACKSON seconded the motion, which was carried unanimously.

The CHAIRMAN: We are very much obliged to you for your renewed confidence in us. I can assure you that we are doing all we can to improve the condition of your Company, and if business improves (and it will be very bad if it does not), we hope that we shall be able to present a more satisfactory report to you next time.

The proceedings then terminated.

Cuba Submarine Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended 30th June last, to be presented at the fortieth ordinary general meeting of shareholders, to be held at the Company's offices, 58, Old Broad-street, E.C., on Wednesday, the 12th inst., at 12 o'clock:—

From the accounts it will be seen that the gross receipts (including the balance brought from last account) amount to £23,586. 2s. 1d., and the gross expenditure (including the half of the annual payment on account of the 1881 cable, and the expenses in connection with cable repairs) to £10,997. 6s. 3d., leaving a sum of £12,588. 15s. 10d. to the credit of revenue account. Of this the sum of £2,656. 5s. 10d. has been added to the reserve fund, which now stands at £78,000. The dividend on the preference shares will absorb £3,000, and leave £6,932. 10s., out of which the Directors recommend the payment of a dividend on the ordinary shares at the rate of 8 per cent. per annum, free of income tax, the balance, £532. 10s., being carried forward to the current half-year's account.

The Company's engineer, Mr. Keith, who superintended the submersion of the new cable between Batabano and Cienfuegos, reports that it was well laid, and has been tested with satisfactory results. The Cienfuegos-Santiago 1875 cable, which became interrupted on January 13th, as mentioned in last report, was restored to working order on February 3rd, while the Batabano-Cienfuegos 1870 cable, which was broken on February 22nd, was repaired on March 28th. These repairs were economically carried out by the Company's engineer, and the whole cost is charged against the revenue of the half-year. The Cienfuegos-Santiago 1881 cable, referred to in paragraph 6 of the last report, has been repaired at the cost of the contractors.

The whole of the Company's submarine system is now in duplicate and in good working order. The suit against the Spanish Government for the protection of the Company's concession is progressing, and the full statement of the Company's case has been lodged with the Contencioso Court.

The Directors have, with much regret, to announce the death, on 22nd February, of Mr. Horatio J. Perry, who had been a Director from the commencement of the Company, and had well served its interests at Madrid. Mr. Charles Woodbyne Parish has been appointed in his place. The Director who retires from the Board at this time is Mr. Thomas Greenwood, who, being eligible, offers himself for re-election. Mr. John Gane, the auditor, also retires, and offers himself for re-election.

City and South London Railway Company (Limited).

The following is the report of the Directors to be submitted to the half-yearly ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, London, E.C., on Tuesday, August 11, 1891.

In presenting their report and statement of accounts for the half-year ended June 30, 1891, the Directors have to report with satisfaction that the railway has been worked, during that period, without accident to any passenger or to any of the staff employed. Although occasional delays to the traffic have occurred through defects in the rolling stock, or other

Digitized by Google

similar causes, these were at first to be expected during the working of a new and untried system of locomotion, and it is a matter for congratulation that in all these cases the delay has been of very short duration, and the regularity of the working is steadily improving.

The receipts during the half-year from all sources amount to £19,688. 2s. 4d., and the expenses for the same period to £15,520. 16s. 5d., leaving a net profit of £4,167. 5s. 11d. The net revenue account shows a balance of £4,693. 3s. 8d., of which amount the interest on debentures absorbs £4,137. 16s. 6d., leaving a balance of £555. 7s. 2d. to be carried forward to the next account.

In the beginning of a new undertaking, many of the items of expenditure are necessarily high, but your Directors have satisfaction in stating that some of these have already been considerably reduced, and further reductions will, from time to time, be made, so far as is consistent with the safety of the public and the interests of the Company.

During the half-year the number of passengers carried by the railway has been 2,412,343. For a considerable time a uniform charge of twopence for passengers was adhered to, but it has been found necessary, in order to compete with the omnibus and tramway traffic, to reduce the charge at certain stations to one penny during stated hours. This has been found to work advantageously, both in the Company's interest and to the convenience of the public.

Two additional locomotives are now nearly ready, and one train of the new carriages has already been received. The completion of these, and the additional generating engine and dynamo now in course of construction, will allow of a considerable increase in the train service.

The action taken by the London County Council, in November last, to contest the right of the Company with respect to the line of frontage at Kennington and the Oval stations has been decided in favour of the Company by the Court of Appeal.

The Bill promoted by the Company in Parliament for an extension of the line to Islington failed to pass the Committee of the House of Commons, and the Directors regret that a valuable aid to the traffic of the existing line and a great accommodation to the public has been in consequence delayed.

Your Directors regret that, owing to other engagements, Mr. Walter Robinson has decided to resign his seat at the Board, and the vacancy so created has been filled by the election of Mr. S. Barclay Heward, of 57, Old Broad-street, London.

NEW COMPANIES, STATUTORY RETURNS, &c.

ELECTRICAL ASSETS PURCHASE COMPANY (LIMITED).—This Company was registered on July 28, 1891, with a capital of £1,000 in £1 shares, by Messrs. Robinson and Stannard, 19, Eastcheap, E.C. The objects are: To purchase the whole of the assets and effects of the Liepmann Carbon Company (Limited), including its British and foreign patents for "Improvements in the manufacture of carbons for electric lighting," to work the said invention, to manufacture carbons for electric lighting purposes, in the form of rods, discs, plates, tubes, or otherwise, and generally to carry on the business of electricians and electrical engineers. The number of the Directors is not to be less than two, nor more than five; remuneration as fixed by the Company at the general meeting, provided that, in addition, they receive a fee of 10s. 6d. for each meeting. Office, Eastcheap Buildings, 19, Eastcheap, E.C.

EPSTEIN ELECTRIC ACCUMULATOR COMPANY (LIMITED).—This Company was registered on the 31st July, 1891 (with a capital of £101,000, divided into 100,000 ordinary and 1,000 founders' shares of £1 each) by A. L. Foley, Marsemore-mansions, South Hampstead. The objects are: To acquire the patents and patent rights of Mr. Ludwig Epstein relating to the invention of and improvements in the manufacture and use of secondary or storage batteries; to manufacture secondary batteries under the said patents or patent rights, or according to the said invention or any improvements thereon; to carry on the business of an electric light company in all its branches; to construct, lay down, establish, fix, and carry out all the necessary engines, wires, cables, lines, accumulators, lamps, and electric plant or apparatus; to generate, accumulate, distribute, and supply electricity for the lighting of cities, towns, streets, docks, markets, and places public and private; and to carry on the business of electricians, electrical contractors, electrical and mechanical engineers, merchants, bankers, brokers, shippers, shipowners, &c. The first subscribers are:—

	Shares.
Sir J. D. Mackenzie, Bart., Worcester-park, Surrey	1
H. G. Rawson, 6, Pump-court, Temple	1
L. Epstein, 5, Cambridge-villas, East Twickenham	1
J. Maier, Ph.D., 23, Melrose-gardens, W.	1
G. T. Broadbridge, 55, Doddington-grove, Kennington-park, S.E.	1
F. Harland, 69, Lavender-sweep, Clapham-common	1
J. Davies, 46, Derby-road, Croydon	1

The number of Directors is not to be less than three, nor more than 12, the first to be appointed by the subscribers. The remuneration of the Board of Directors will be determined by the Company, from time to time, in general meeting.

"ENERGY" GAS, ELECTRIC LIGHTING AND POWER COMPANY (LIMITED).—This Company was registered on the 1st August, 1891, with a capital of £20,000 in £1 shares. The objects are to apply for purchase or otherwise acquire patents, licenses, or other rights in connection with inventions having for their object the giving of new qualities to gas or the suppressing of its defects, and particularly the making of gas cheaper and giving it the appearance of electric light. To create a lighting industry having the qualities of electricity without the disadvantages of either. To carry on the business of manufacturers of and dealers in incandescent lights, and generally that of a Gas, Electric Lighting and Power Company. The subscribers, each of whom takes one share, are Eugene Destruels, Albert Daude, Joseph Louis, Paul Fernand, Attmar Kern, Paul E. Sautreau, and Thiebaut Apfler, all of Paris. Registered by A. Herbelet, 5, Chancery-lane, W.C., without Articles of Association.

FIELD'S "M.P." DEVELOPMENT ASSOCIATION (LIMITED).—This Company was registered on July 28, 1891, with a capital of £100,000 in £1 shares, by Hays, Schmettan and Co., 31, Abchurch-lane, E.C. The objects are: To purchase, take over, and work the whole of the patents mentioned in the Memorandum of Association, 49 in all, granted in or applied for and not yet issued. British (5), Belgium (3), Austria (2), Brazil (2), Canada (2), Italy (2), France (3), Germany (2), Luxemburg (2), New South Wales (2), New Zealand (2), United States (4), Queensland (2), South Australia (2), Spain (2), Switzerland (2), Denmark (2), India (2), Victoria (2), Norway (2), Sweden (2). To carry on, *inter alia*, the business of an electric light company in all its branches, to construct, lay down, establish, fix and carry out all necessary cables, wires, lines, accumulators, lamps and works, necessary for the generation, accumulation, distribution, and supply of electricity, and to carry on business as engineers, boiler makers, dealers in engines, boilers, motors, iron, steel, copper and other metals, electricians, electrical engineers, contractors for electric lighting, merchants, bankers, brokers, shippers, or otherwise. The number of Directors is not to be less than three, nor more than nine, the first to be elected by the subscribers to the Memorandum of Association. Qualification: 250 shares. The Board of Directors, exclusive of Managing Directors, are entitled to a remuneration of £1,500 per annum, to be divided as they themselves may determine.

WATER METER AND GENERAL TRADING SYNDICATE (LIMITED).—This Company was registered on the 28th July, 1891, with a capital of £15,000 in £1 shares, by J. A. Weston, 526, Mansion House Buildings, 11, Queen Victoria-street, E.C. Objects (amongst others): To construct, originate, conduct, contract for, develop, manage, control and work scientific, electric, telegraphic, telephonic, tramway, and other industrial undertakings, and to promote and establish companies or private undertakings with objects similar to the above. Registered without Articles of Association. Office: 526 and 527, Mansion House Buildings, 11, Queen Victoria-street. E.C.

BIRMINGHAM ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of the above-named Company, made up to the 10th June, 1891, was filed on the 7th July, 1891. The Company, which was registered on the 2nd December, 1889, has a capital of £100,000 in £5 shares; 10,006 ordinary and 1,800 special issue shares have been taken up, and upon all of the former the full amount has been called, while upon all of the latter 5s. per share has been called. The calls paid amount to £49,597. 10s., and unpaid to £882. 10s. Office, 14, Dale End, Birmingham.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to May 13th, was filed on May 22nd last. The Company has a nominal capital of £500,000, divided into 49,900 ordinary and 100 founders' shares. 45,932 ordinary and 100 founders' shares have been taken up, making a total of 46,032. Upon 43,900 of these £9 per share has been called, and upon the remainder the full amount has been considered as paid. The calls paid amount to £392,500. 9s., unpaid to £2,599. 11s., and the amount considered as paid is £21,320. Office: Winchester House, Old Broad-street, E.C.

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 29th, was filed on June 4th last. The nominal capital is £300,000, in £10 shares, all of which have been taken up, on each of which the full amount has been called, and all calls are paid. Office: 120, Cannon-street, E.C.

WILLIAMSON ELECTRICAL AND ENGINEERING COMPANY (LIMITED).—At an extraordinary general meeting of the above-named Company, held at 14, St. Ann's-square, Manchester, on July 3, 1891, the following special resolution was passed, and at a subsequent meeting held on July 21, 1891, duly confirmed:—"That the capital of the Company be increased to £25,000 by the creation of 2,000 new shares of £10 each." The notice of the meeting was filed on the 28th July, and the statement pursuant to Section 2 of the Customs and Inland Revenue Act, 1888, on July 31, 1891. Office, 14, St. Ann's-square, Manchester.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the past week amounted to £5,152.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The traffic receipts of this Company for the past week amounted to £692.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of July were £3,100, as compared with £3,134 in the corresponding month of last year, showing a decrease of £34.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of July, 1891, amounted to £1,667, as against £2,016 in the corresponding period of last year, or a decrease of £349.

Digitized by Google

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of July, 1891, amounted to £52,303, and to £54,224 in the corresponding period of 1890, a decrease of £1,921.

EASTERN EXTENSION TELEGRAPH COMPANY.—The receipts of this Company for July amounted to £41,219, as against £46,367 in the corresponding period of last year, showing a decrease of £5,148.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company are as follows:—Receipts in July, 1891, £24,400; 1st January to 31st July, 1891, £165,800; corresponding months, 1890, £156,000; corresponding months, 1889, £154,200. The reduction in the rates, which was agreed upon at the Telegraph Conference in Paris, came into force on the 1st of July. The Company's new cable between Denmark and France was successfully laid during the month.

P. AND J. MACLELLAN (LIMITED).—The Directors have declared an interim dividend of 6s. per share on the preference shares, being at the rate of 6 per cent. per annum, payable on the 11th August.

A. AND J. STEWART AND CLYDESDALES (LIMITED).—The Directors have resolved to pay an interim dividend at the rate of 6 per cent. per annum on the preference shares (less income-tax) and at the rate of 8 per cent. per annum on the ordinary shares, free of tax, for the half-year to June 30, 1891, to shareholders standing registered in the books at July 30, 1891.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the weeks ended July 17th and 24th, 1891, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were respectively £2,280 and £3,319.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this Company for the month ended July 31st were £2,075.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the half-month to July 31st amounted to £2,058, as compared with £2,702 for the corresponding period last year, showing a decrease of £644.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 691.—Vol. XXVII. FRIDAY, AUGUST 14, 1891. Price Fourpence.

NOTES.

Although the results of the first half-year's working of such a novel concern as the City and South London Railway are not to be taken as a criterion of its ultimate possibilities, the great interest which is everywhere taken in this experiment warrants a somewhat close examination of the figures which were placed before the shareholders on Tuesday. Since the opening of the line no less than 2,412,343 passengers have been carried, and 141,408 train miles have been run. The receipts per train mile from all sources during the half-year ended on June 30th have been a trifle over 2s. 9d., against the Metropolitan Company's average of 7s. The number of passengers carried per train mile comes out at 17, against 43 in the case of the Underground. It is to be remembered, however, that the trains on the Metropolitan Railway are more capacious than those on the electric line. The receipts from all sources amounted to £19,688, to which sum passengers contributed £19,403. The total expenses for the same period have been £15,520, leaving a net profit of £4,168 for the half-year. To pay 5 per cent. for the half-year on the capital actually expended up to date would require some £20,000.

The Directors of the City and South London Railway have, therefore, no light task before them. A reduction of the working expenses, which are at present over 78 per cent. of the gross receipts, to the normal figure of 50 per cent., and an increase in the revenue, are imperative, if the public are to be satisfied that electricity can pay. The latter desideratum will probably be partially attained so soon as there is the promised regular and rapid and comfortable three minutes' service; but extensions North and South will, in the end, have to be made before the City and South London Railway is as prosperous as we all wish to see it.

The resolutions which were passed at the meeting of the Electrical Trade Section, on Friday last, represent pretty accurately the prevailing feeling on the subject of electrical exhibitions in general, and the proposed one at the Crystal Palace in particular. The bands, coloured lights, and toys attract the shilling-paying public, and enable the promoters of these shows to sometimes score a success, but something more solid is required to attract *customers*. Now, it is to the customer that heavy electrical engineering firms look to recoup themselves for the expense inevitably attendant on exhibiting, even when the exhibitors, as at the Crystal Palace, are not to be mulcted for floor space. The promoter and the exhibitor, as Mr. Crompton said on Friday, therefore, regard the matter in a somewhat different light.

Such being the case, it is not surprising to find that the Directors of the Crystal Palace Company intend to go on with their Exhibition, although they have decided to postpone the date of opening until January 1, 1892, and no one can blame them. No less than 56 firms have, they say, already applied for space. There will be the usual disproportionate representation of young and pushing firms, and plenty of coloured lights, art fittings, electric bells and telephonic "auditions," and last, but not least, the phonograph. The public will pay their shillings, and all will be well—from the Directors' point of view. But the heavy engineering firms, the backbone of the electrical industry, will have no time to prepare worthy exhibits, and a thoroughly national and representative Exhibition, such as alone might benefit them, is not, therefore, probable.

There was one feature of last Friday's proceedings which is worthy of notice, namely, the manner in which electric lighting alone was apparently thought of by the Crystal Palace Directors. Since the Exhibition of ten years ago, to which they referred with such natural pride, electric lighting has become a comparatively routine business, even in this country, and in an Exhibition thoroughly representative of the state of the industry, transmission and distribution of power, electric traction, electric haulage, and electric pumping should almost overshadow the lighting exhibits.

There is much to be said for the usefulness of non-mathematical speculation for a pioneering expedition into the unknown land of ether theories and the *vera causa* of electrical phenomena. The subject is so complex and obscure that to endeavour to map out the country on elaborate geodetical principles is not only extremely laborious, but the landmarks are so rare, and the intervening jungle is so dense, that progress must be both tedious and uncertain. A sketch map contains a good deal of information of a common-sense order, though the bearings may be erroneous, while a trigonometrical network, though marvellously accurate, is of little use to a traveller. Mr. Tolver Preston has made many speculative advances of this kind, and the article which we print in another column contains, without any attempt to dogmatise, much that is suggestive. It is time enough to dogmatise when the subject has become ripe for mathematical treatment, and when theory has been verified by ex-

Digitized by Google

periment. The author is undoubtedly correct in thinking that an inelastic ether is unintelligible, but he goes further than the ordinary idea of shearing, and asks that the ether may be "to some extent compressible." But the "ether rarefaction" plays so important a part in these interesting "rough ideas," that we do not think the objections to this hypothesis are so trifling as is assumed.

WHILE modern physics teach that the old ideas of potential energy cannot be held to exclude and to be the opposite of kinetic energy, it is not safe to set up important distinctions between dynamical and statical phenomena, but the idea of treating waves as stationary appears to be useful as a working hypothesis. The figures given by Mr. TOLVER PRESTON, showing that 7,000 H.P. transmitted at the velocity of light (which it must be if the ether comes into play at all) demands a stress of only 26 or 27 grains, are very interesting, and serve to show the great difficulty of measuring or even detecting energy flow on a moderate scale.

ACCORDING to MAXWELL'S electro-magnetic theory, electric waves are propagated with the same velocity along conductors as through the air. Several of the earlier experiments of Prof. HERTZ seemed, however, to point to a different conclusion, and a considerable amount of discussion has lately taken place, chiefly among French physicists, in connection with the subject. Some important errors in interpreting the experimental results have been pointed out, and MM. LECHER, SARASIN, and DE LA RIVE have made further experiments, the results of which seem decidedly to show that the two velocities are the same. Prof. HERTZ, in a short article which we publish in this issue, declares that this has been his conviction all along, in spite of the fact that many of his experiments gave a contrary result. He points out that laboratories of ordinary dimensions are too small for properly carrying out investigations of waves of the great length usual in electric oscillations. When shorter waves of about 30 centimetres or less are used, no discrepancy between the two velocities has ever been found to occur.

THE rotary current system, to call it by the most commonly used of its many aliases, seems likely to give rise if not to a fine crop of lawsuits, that invariable concomitan of every electrical invention of value, at any rate to a vigorous controversy as to its true originator; indeed, according to Prof. DU BOIS-REYMOND, whose interesting communication to the *Electrical World* of New York we reprint in another column, "the question of who deserves the credit of being the only original inventor of electro-magnetic rotation is at present being ventilated with great ardour among the technical public all over Europe." At the present moment Prof. FERRARIS and Mr. NIKOLA TESLA, or rather their respective advocates in the technical Press, are contending as to the priority in discovering the principle, and probably the question which is being "ventilated with great ardour" on the Continent is whether BROWN or BRADLEY, DOLIVO VON DOBROWOLSKY or HASELWANDER, was the first to apply in a practical manner the principles first clearly enunciated by Prof. FERRARIS and to develop the first rough motor made by Mr. NIKOLA TESLA.

As far as England was concerned, and judging by our own order of publication, there was something approaching absolute simultaneity between the two workers, situated, as Prof. DU BOIS-REYMOND remarks, with "a few thousand miles of land and sea between them." In an editorial note, which appeared in *The Electrician* of May 25, 1888, we remarked: "In another column will be found an account of a highly interesting and ingenious device of Prof. FERRARIS, who, by means of the combination of two alternating fields displaced by a quarter phase, obtains the practical equivalent of a rotating field. That the device will readily lend itself to the construction of an alternate current meter is almost certain, but whether it will make a practical motor it is yet too early to speak with confidence. There can be little doubt, we think, as to the novelty of the idea, so far as regards previous publication; and yet we hear this week from America of a device which, so far as our information at present goes, seems to bear a good deal of similarity. This latter invention is due to Mr. NIKOLA TESLA, and he was to have read a Paper on the subject before the American Institute of Electrical Engineers on the 16th of the present month. One of the Transatlantic journals has already published an article, based, evidently, upon the patent specification, but we must confess that we are unable to make head or tail of the details." In our issue of June 15, 1888, we published the paper of Mr. NIKOLA TESLA referred to above.

IT is with pleasure that we find ourselves in perfect accord with Prof. DU BOIS-REYMOND as to the futility, except for the baneful purposes of patent litigation, of these disputes regarding priority. No two individuals will probably agree as to the respective value of actual publication in a monograph and potential publication by filing an application for a patent, but we think that everyone who has followed the history of this, the latest, development of alternate currents will be of opinion that there never was a clearer case of independent and simultaneous discovery of the same thing. If Prof. FERRARIS enunciated the principle more clearly, Mr. NIKOLA TESLA gave a more practical turn to the motor; and the names of FERRARIS and TESLA should be linked together in honourable union in history. Of course, the ingenious minds, with the bump of historical research abnormally developed, will not take kindly to this solution of the difficulty, but will continue to hunt down the "absolutely first," who, truth to tell, rarely exists, and, when he does, seldom repays the time devoted to the research. To this eagerness for priority may, indeed, be attributed the many immature Papers with which the scientific world is frequently regaled—Papers published in a hurry to "take date."

AT the moment of going to press we received the following telegram from our Glasgow correspondent:—

"At the meeting of the Town Council to-day (Thursday) Councillor Bell, Convener of the Electric Lighting Committee, stated that the Committee had resolved to take the advice of Sir William Thomson regarding various matters which had recently cropped up, and which were of vital importance to the question of the electric lighting of Glasgow. Under the circumstances he respectfully requested Councillor Colquhoun to delay his motion for rescinding the resolution of a former meeting regarding the adoption of the low-tension system in Glasgow. Councillor Colquhoun had great pleasure in acceding to the wish of the Committee that his motion should be postponed."

The whole question of the system to be adopted in Glasgow seems, therefore, likely to be re-opened.

Cork.—The Directors of the Cork Gas Consumers' Company contemplate seeking powers to supply electric light.

East African Telegraphs.—The German Government has decided, says a Berlin telegram, to establish telegraph lines along the whole of the German East African coast.

University College of South Wales.—The Council of this College is prepared to appoint a Professor of Mining. Further particulars will be found in our advertisement columns.

Erding (Bavaria).—Tenders are invited for the supply of the necessary plant for the electric lighting of this town. Water-power to the extent of 60 H.P. is available.

Projected Electric Railway between Baden and Voslau.—Messrs. Ganz and Co. have obtained the concession for constructing an electric railway between Baden and Vöslau.

New Cable between England and Germany.—The laying of a new cable between Bacton, near Lowestoft, and Emden, at the mouth of the Ems, has been completed by the cable ship Faraday.

Holborn District Board.—At the last meeting of this Board a letter was read from the County of London Electric Lighting Company, stating that they intended to apply for a Provisional Order.

Cambridge.—The Town Clerk has received an official intimation from the Local Government Board that a fresh inquiry will be held as to the desirability of granting the Electric Lighting Loan.

Manchester Technical School.—Premises have been taken by the Council of this School for the purpose of establishing a practical training school of electrical engineering. The school is to be ready during the coming winter.

Maidstone.—At a private meeting of the Local Board, on Tuesday, the question of supplying the town by electricity was considered, and it was resolved to apply for a Provisional Order, and, if possible, to put the supply into the hands of an electric lighting company.

The Victorian Electrical and Telegraphic Journal.—The editors of this journal announce in their June issue that with their July number the publication of the journal will come to a close. It was first published in August, 1886, and has made a regular monthly appearance ever since.

Old Students' Association.—The Committee of this Association announce that a garden-party (tennis and music) will be held in the grounds of Glebe Lodge, Champion Hill, on Saturday, September 5th, from 3 to 7 o'clock. Tickets (2s. 6d. each) may be had of Messrs. W. B. Esson, C. E. Holland, or Reginald Jones.

Chicago Exhibition.—Sir Henry Trueman Wood has been instructed by the Council of the Society of Arts to at once visit Chicago, and he will leave England for this purpose early in September. Exhibitors likely to require special arrangements made for them are requested to communicate with him before his departure.

Electric Construction Corporation.—The Managing Director of this Corporation (Mr. Ebb-Smith) has resigned his official position, and has been elected to the seat on the Board vacated by the decease of Sir R. N. Fowler, Bart. Mr. Thomas Parker, the present Works Director, will in future act as General Manager of the Corporation.

The Dyne.—According to Mr. John T. Grier, in the *Electrical Engineer* of New York, "we may roundly define a dyne in language that will be more likely to stick to the memory and be more easily grasped by some if we slightly paraphrase the definition and say it is that force which, acting for one second on a mass of matter equal in weight to four-tenths of a dime, gives to it a velocity of almost four-tenths of an inch per second."

Liverpool Overhead Railway.—At the half-yearly meeting of the Liverpool Overhead Railway Company, on Tuesday, Sir W. Forwood stated that considerable progress has been made with the line during the past half-year, no less than £85,620 having been expended, out of a total expenditure up to date of £143,098. The Directors, he said, had finally decided to use electricity as the motive power, and a contract with the Electrical Construction Corporation to work the line for two years at 3½d. per train mile for locomotive expenses had been concluded. The line would probably be opened in the spring.

Accident on the Lichterfeld Electric Railway.—An accident occurred on this line on the 25th ult. About half-past eight the car left the Potsdam station, but when a little way out it came to a standstill, owing to the cessation of the supply of current. The conductor left the car in order to ascertain the cause of this, and returned to the station. In the meantime, however, the car also started towards the station. It ran through the buffers at the end of the line, and was brought to rest by the wheels sticking in the soft earth. Apparently no one was hurt, and the car was soon able to be run again.

The Effect of Electric Light on Fish.—"Duty," says a correspondent to *Land and Water*, "took me to Totland Bay a short time since. In answer to my inquiries about the sea-fishing, I was told that the fishing all along that part of the Isle of Wight was very poor, and that since the setting up of the search light for the forts it had become worse. I also heard that there used to be a very good place for fish near the lighthouse at St. Catherine's Point, but that the electric light had driven them all away, and now it was quite useless putting out nets in a spot where a few years since a decent haul was looked on as a certainty."

Helston.—At a recent quarterly meeting of the Town Council, the proposed electric lighting of the borough was further discussed. Mr. J. E. Veale, of St. Austell, presented a report on the subject, in compliance with the request of the Special Committee which had been appointed to consider it. He declared that it was quite possible to light the town by electricity, and that the present disposition of the town lighting would adapt itself well to the new illuminant. Mr. Dale moved that the Council decide upon lighting the borough by electricity, and that water power be used for the purpose, the details to be left to a Committee. The resolution was carried.

The St. Pancras Central Station.—The Electricity Committee of the St. Pancras Vestry inspected the electrical works on July 30th, and found that four engines and dynamos had been erected. As to the work of main laying, the Committee report that it is proceeding rapidly. At the Cobden sub-station good progress is being made. The Committee are about to issue advertisements for the staff of officers. The proposed staff for the works consists of a resident enginner, at £4 per week; two engine drivers, at £3 per week; two dynamo attendants, at £3 per week; inspector of private works, £2.10s. per week; six stokers, at 25s. to 35s. per week; storekeeper and attendant at sub-station, care of arc lights, &c., 35s. per week.

Thunderstorms.—During the past week or ten days the usual crop of thunderstorms has occurred in various parts of the United Kingdom; considerable injury being done to life and property. On the 3rd inst., an agricultural labourer was killed by lightning near Lincoln. On the 4th, during a heavy thunderstorm which passed over St. Helens, the York Hotel was struck. The chimney stack was damaged, the paper stripped from the walls, the joists set on fire, portions of the gas piping were melted, and the meter entirely disconnected. On Monday last, during a thunderstorm at Horndon-on-the-Hill (Essex), a lad, while at work in a pea-field, was struck by lightning and killed. On the same day, 47 sheep were killed by lightning at Overton, near Marlborough, and others were injured. In various parts of the country hay ricks have been fired, houses struck, and cattle killed.

Electric Lighthouses.—Some complaints regarding the electric light at sea have been made to the Trinity House by the Shipmasters' Society. The secretary (Lieutenant Froud) informs the Deputy Master and Elder Brethren that members of the Society in active service, passing from the Thames to sea and *vice versâ*, have often represented to the Committee the poorness, sometimes invisibility, of electric lights during certain conditions of hazy atmosphere. Fault is also found with the intense and blinding effects of such lights as those of the South Foreland on vessels near at hand. To remedy the latter of these defects, it is suggested that coloured glass or other media might be used to tone the light; while to prevent the rays being entirely lost in fog or haze the captains recommend that lighthouses, especially where there is a background of land, should send a beam vertically upward.

Crystal Palace Electrical Exhibition.—We are informed that the Directors of the Crystal Palace, in deference to the wish of the Electrical Trade Section of the London Chamber of Commerce, have finally decided to postpone the opening of the Electrical Exhibition from November, 1891, till January 1, 1892, on which date the exhibition will be formally opened. The following are a few of the gentlemen who have consented to act as an Honorary Council of Advice:—Prof. W. Grylls Adams, Prof. W. E. Ayrton, Mr. H. R. Beeton, Mr. Shelford Bidwell, Major Cardew, Sir Daniel Cooper, Bart., Mr. J. I. Courtenay, Prof. W. Crookes, Mr. W. B. Esson, Mr. S. Z. de Ferranti, Mr. J. E. H. Gordon, Mr. E. Graves, Mr. J. H. Greathead, Mr. R. Hammond, Dr. Hopkinson, Prof. D. E. Hughes, Mr. Gisbert Kapp, Prof. A. B. W. Kennedy, Mr. A. E. Mavor, Mr. W. M. Mordey, Mr. W. H. Preece, Prof. Henry Robinson, Sir David Salomons, Bart, Mr. Alexander Siemens, Prof. W. C. Unwin, and Major-General C. E. Webber.

Exports of Telegraphic Apparatus.—The Board of Trade returns for July show no diminution in the satisfactory expansion of telegraphic wires and apparatus connected therewith, which has been noticeable since the beginning of the current year. The exports for July were exceptionally large, and the aggregate figures for the seven months show an increase on the corresponding large totals of both 1890 and 1889. In the following table we show the value of the exports for the seven months, in comparison with the corresponding figures for the two previous years:—

	1891.	1890.	1889.
First quarter ...	£653,081	£324,670	£431,309
Second quarter..	331,449	397,042	145,147
Six months	984,530	721,712	576,456
July	150,754	56,575	32,909
Seven months...	1,135,284	778,287	609,365

Patent Litigation in America.—In 1888, the Gaulard and Gibbs patent, held by the Westinghouse Company, was invalidated, and since then that Company has refrained from offensive warfare. An action has, however, now been brought against a local electric lighting company, in Vermont, by the Westinghouse Company, on the strength of Mr. Rankin Kennedy's English patent of 1883, which it owns. This patent claims "the method of distributing and regulating alternating electric currents by secondary generators, which consists in producing in two or more derived circuits constituting the primaries of two or more secondary generators a counter electromotive force which, when any secondary is open, is practically equal to the applied electromotive force in its primary and in controlling said electromotive force by the current flowing in the corresponding secondary when the secondary is closed in such a manner that the current in the primary shall vary with, and be approximately inversely proportional to, the resistance in the secondary, substantially as described."

Search Lights in the Naval Manœuvres.—Many years' experience of search lights in naval sham fights, says *The Times* correspondent convinces me that these machines, which, in certain circumstances are invaluable, are too often so utilised as to be of far more assistance to the attack than to the defence. When an ironclad, believing that torpedo boats are near her, but seeing none of them, begins flashing her search lights in order to discover the enemy, she greatly helps her foe, who thenceforward knows exactly where and how she lies, and to what quarter her uneasy suspicions are directed. By all means cover the mouth of your anchorage with permanent and steady beams of light, so that any craft entering must cross the beams and so reveal herself; but do not let these beams proceed from battleships, or, indeed, from big ships of any sort. They should be thrown only from small craft and from boats, or, still better, from points on shore. The only time, in my humble opinion, when a threatened battleship should use her light is when she has already clearly discovered an approaching enemy. Then let her flash it full into his eyes. It will blind and puzzle him, and, falling on his hull, guns, and paintwork, it will give her a capital target for gunfire. Splendid, when thus used, was the effect of the light upon torpedo boat No. 25, in Luce Bay, on the morning of July 27th. From the moment when the beam struck the boat she was as good as destroyed, for she stood out so clearly that only very bad gunners could have missed her. The light ought not to be worked from any point very near the guns which are to be fired. The ideal position is as far as possible below them. It is, all things considered, a mistake to mount lights on bridges and chart-houses; they cannot be too close to the surface of the water.

Electrical Development in the Sandwich Islands.—The streets of Honolulu, says Mr. J. Cassidy, in a recent issue of the *Electrical Engineer* of New York, are lighted by 92 arc lights of 2,000 c.p. of the Thomson-Houston system, and the dynamos are driven by water-power. The same station furnishes 800 incandescent lights for residences and stores. This plant is the property of the Hawaiian Government. The Queen's Palace has a private plant of one Armington and Sims engine and two Thomson-Houston low-tension dynamos, with a capacity of 600 lights. The Honolulu Iron Works have a plant of 75 lights, operated by a Mather incandescent dynamo. The Union Iron Works have an Edison plant of 75 lights. This enterprising concern have a Thomson-Houston motor in their pattern shop, and have now ordered a welding machine. The telephone industry is also in good condition. Honolulu itself has a population of 22,000, and a telephone system of 1,200 subscribers. On the island of Hawaii there are two telephone companies—the Hawaii Telephone Company and the Hilo Telephone Company. The Maui Telephone Company is on the island of Maui, and the Kaui Telephone Company is on the island of Kaui. The telephones in use are from the American Bell Telephone Company, of Boston. The large plantations have also extensive private telephone service of their own. All telephone instruments and material are free of duty when entered by the Company itself, giving the Company an advantage over the merchants in the importation of electrical goods. Copper wire is extensively used in the construction of telephone lines, because of the salt air. A No. 12 iron wire circuit, nine miles long, has been known to fall to pieces in less than two years, owing to the chemical action of salt water spraying on the galvanised iron. There is also a general use of the telegraph in the island, and one hears a great deal about submarine cables between the Sandwich Islands and the American Continent. The great need of the kingdom is inter-island cable communication.

Edison's Counsel.—The examination of Mr. Edison in the recent lamp patent case gave rise to some statements on his part worth recording, and the speech of his counsel, Mr. Grosvenor Lowrey, was equally fruitful. "Sir William Thomson," remarked Mr. Lowrey, "that great authority, that really wise man, the sort of man who probably did not understand Ohm's law; who, if you had asked him, would probably have said he once thought he did, but was finding out so much every day he was not sure now, had said: 'It is quite possible that a plan of using electrical energy for light may yet be found, in which ten feebler lights will give a sum equal to that obtainable by the same energy in one concentrated light.' . . . . It had not occurred to Sir William Thomson that there were several ways of getting around a stump; that way had to be found out from this practical fellow at Menlo Park, who was so ignorant. He (Mr. Lowrey) had often thought what an awful thing it would have been for the world if Thomas A. Edison had the misfortune to be educated at Stevens Institute. Then he would have known, as they all knew, the mathematics, and then he would have known, too, what things could not be done. There was reason to be grateful that it was not everybody to whom the fortune of a liberal education came, because in this business of investigating nature a liberal education often enslaved the mind. There was Prof. Elihu Thomson; he understood him to be of the opinion that it had been a mere matter of electrical engineering to make this lamp; all the required laws were known, and the rest was mere ciphering. Now, Prof. Thomson was an expert cipherer; he was a professor in Pennsylvania; an inventor; a man of excellent ability. He had been engaged in the search after a small light before Edison began, but it had never once occurred to him to sum up all these outstanding unused laws, which he knew so much about, and evolve the light before us."

MAGNETISM IN IRON AND OTHER METALS.*—XLVII.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 380.*)

§ 165. **Experiments with Rough Joints.**—Others of the experiments dealt with bars which were simply cut in the lathe, without having the cut ends afterwards scraped to the form of true planes. Joints of this kind, which may by comparison be called rough, were found to offer rather more, but not very much more, resistance than a carefully faced joint, so long as the cut bar was tested without compression. But under compression the difference between a rough and a smooth joint became very manifest; the resistance of the rough joint was comparatively little reduced, and altogether refused to disappear even under the most intense stress.

Table XXVIII. shows the effect of successive cuttings in an iron bar, the joints being in every case of this comparatively rough kind. The bar was tested first in the uncut state, then when cut in two parts, then in four parts, and finally in eight parts, the ends being put in contact without compression.

Table XXVIII.—*Effect of Successive Cuttings.*

Magnetising force due to solenoid.	Magnetic Induction B.			
	Solid bar.	Bar cut in two.	Bar cut in four.	Bar cut in eight.
7·5	8,500	6,900	4,800	2,600
10	11,000	9,000	6,400	3,770
15	13,400	11,550	8,900	5,550
20	14,400	13,000	10,750	7,150
30	15,350	14,550	12,940	9,800
50	16,400	15,950	15,000	13,300
70	17,100	16,840	16,120	15,220

The results of this experiment are also exhibited in Fig. 135, where the full lines show the relation of B to the magnetising force of the solenoid when the bar was in one, two, four and eight pieces. The dotted lines in the same figures refer to a further experiment, in which a compressive stress of 226 kilos. per square cm. was applied, first to the uncut bar, and then to the bar cut in eight pieces.

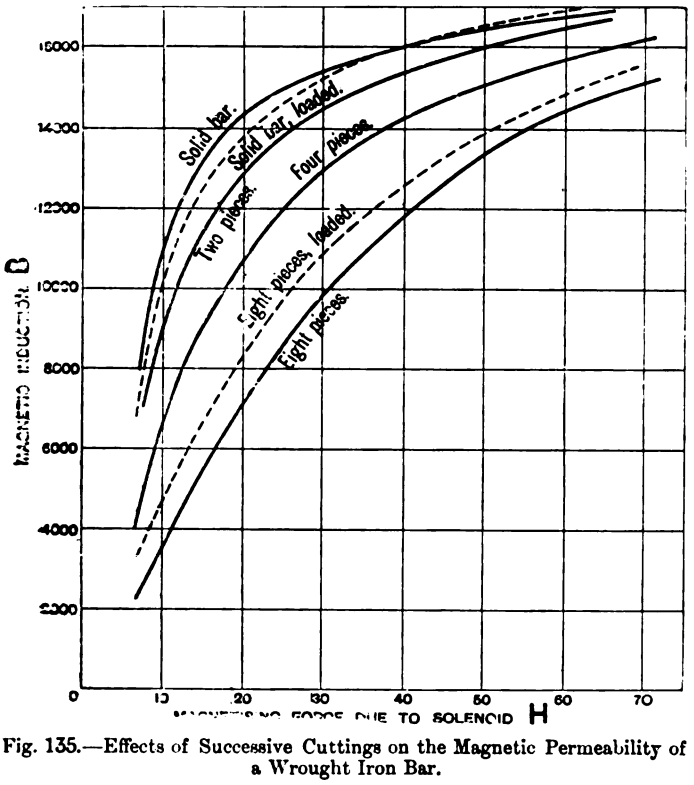

Fig. 135.—Effects of Successive Cuttings on the Magnetic Permeability of a Wrought Iron Bar.

No load .....

Load of 226 kilogs. per sq. centim. -

Comparing the curves for the uncut bar with and without compression, we see that compressive stress lowers the permeability, except when the magnetisation is strong. In strong fields the dotted curve crosses above the plain curve. This gives incidental evidence of the existence of a reversal of the effect of compressive stress, corresponding to the "Villari" reversal of the effect of the tensile stress (see §§ 120, 124-126)—a result to be anticipated from what we know of the behaviour of iron under tension. For values of B below 16,000, however, compression increases the resistance of the circuit so long as the bar is uncut. But when applied to the eight pieces, compression decidedly reduces the resistance of the circuit, even when the magnetisation is weak: the dotted curve for the bar cut in eight lies considerably above the plane curve. In other words, compression lowers, though it by no means destroys, the resistance of the joints, and when the joints are as numerous as they are here, its (positive) effect on them more than neutralises its (negative) effect on the permeability of the metal itself. When the same test was applied to the bar in four pieces it was found the two effects of compression came near to neutralising each other.

In the following table the width of the air-gap which would give the same resistance as the mean of the seven joints has been calculated by the method described above. The results are stated for both cases—with compression and without compression.

Table XXIX.—*Width of air-gap equivalent in resistance to the mean of seven joints.*

B.	Without compression.	With compression of 226 kilos. per sq. cm.
	cms.	cms.
8,000	0·0036	0·0024
10,000	0·0041	0·0031
12,000	0·0046	0·0036
14,000	0·0050	0·0041
15,000	0·0052	0·0041

It appears then that, in round numbers, the resistance of each rough joint was nearly the same as that of a film of air 0·005 cm. thick where there was no compression, and that this equivalent film was only reduced to about 0·004cm. when a compressive stress was applied which would have been intense enough to practically destroy the resistance of the joint had the surfaces been carefully faced. We have seen that a joint with faced surfaces, tested without compression, is equivalent to a film of air about 0·003cm. thick. The thickness of the equivalent film in these rough joints seems to increase a little as the condition of saturation is approached. In the absence of compression a smooth joint is not very greatly better than a rough one. But compression is incompetent to produce, in a rough joint, that extreme closeness of contact which it apparently produces in a smooth joint, in consequence of which the resistance of the smooth joint almost vanishes.

ROUGH IDEAS OF THE MECHANISM OF THE ELECTRIC CIRCUIT.

BY S. TOLVER PRESTON.

Why do we want a circuit at all for the electric current? Why does it appear like a *current*? Why is the so-called "current" uniform everywhere, in spite of the varying resistance of the diverse parts of the circuit? These are questions which present themselves repeatedly at this period of transformation of the science, and thought may afford at least a qualitative answer.

Having, in 1875, in a work, "Physics of the Ether," Appendix, p. 133, arrived at some of the main facts now recognised to be true in regard to the ether action in electric effects, there may be some ground for confidence in developing this further now, and attention is invited to a *radial* (or axial) form of vibration, which would seem to have a most practical bearing on the subject—which is undoubtedly a branch of mechanics.

Digitized by Google

Consider a circuit. Why is a circuit required at all?—or, rather, why *only* under this condition are the magnetic waves (from which the uniformity of the "current" everywhere is inferred) uniform in intensity everywhere? Obviously, surely, because these waves can only abut against themselves, and so adjust their intensity to uniformity, in a complete circuit. If the waves had anything else but themselves to abut or react against; if they were reflected from masses, for instance, the waves, which are certainly (partly) progressive or "dynamical," would cease to be such, and become entirely stationary (or "statical") by reflection. They would cease (if a closed circuit were wanting) to be waves of that character, which are sufficiently stationary to self-adjust their equilibrium to uniformity, and sufficiently progressive to carry the ether impulses from the pile or dynamo, and supply energy to the circuit at the various points where it is absorbed.

Let us consider an arc light. Carbon "absorbs" these waves more than copper; *i.e.*, its molecules take up the motion of the waves more easily. This is parallel to the absorption of light or radiant heat; which waves are now proved to be the same in kind as electric or magnetic waves. We may figure to ourselves these waves as discs, or rather segments, "threaded," so to speak, on the wire (or, take it, *circular* formed circuit), going off to nothing at the centre of the circuit, and in equilibrium of (oscillatory) pressure among each other, like the "voussoirs" of an arch; also meeting at the geometrical centre* of the circuit. [This is, roughly, the known form of distribution of the "magnetic lines."] The wave segments (or, roughly speaking, discs) of ether oscillate, of course, too axially, *i.e.*, radially† from, and radially towards, the wire; as you cannot press an elastic disc of any kind (or vary the pressure) without making it bulge and contract radially. This fact, as a broad conclusion, may be deduced without difficulty; for it is obvious that two elastic masses cannot come into collision or pressure without radial bulging. [Take an india-rubber buffer, for instance.] That this alternately varying lateral pressure exists in the segments into which the ether of the circuit is broken up, we know for a certainty; for otherwise (obviously) no self-adjustment of equilibrium among the waves or pulses would be possible, which we are sure does occur. Well, of course, this ring-like grip alternately varying in intensity of the ether about the wire, as the radial vibration goes on which accompanies the (abutting) longitudinal oscillation ‡ of the ether segments, or voussoirs in partial stationary vibration (often defined by drawing the "magnetic" lines round the wire)—we see, I repeat, that this partial rush of ether radially out from the wire and alternate rush in at each vibration of each segment, heats the wire or circuit more or less, according as the molecules can more or less take up the motion. There is no vagueness here; for such a movement of the ether is exactly calculated to heat the wire (which it penetrates), as any mechanical mind will see. How is the vibratory movement controlled radially (or rendered stable), it may be said? Why, obviously as the air resonance in an open pipe (is controlled) by producing a *rarefaction* at the centre of the movement So a rarefaction of the ether at the axis of the wire, all along it (and it is a complete circuit without end) is produced; and so the wire forms the axis of* radial vibration.

Now, carbons (of an arc) can take up the motion easily, and so are intensely "heated," as we term it. Of course, the "heating" of the carbons, and consequent loss of energy by the electric or magnetic waves in the act of achieving this, weakens the pressure or energy of the magnetic oscillations where the arc is, or would do so considerably if the adjacent waves (which abut) did not come to the rescue, and give up by simple exchange of motion their energy (unimpaired) to the partially exhausted waves. So a wave disturbance rolls round the circuit, or the arc "draws" energy† to itself in this way, and it soon reaches the dynamo, which at every revolution adds fresh magnetic waves or impulses to the equilibriated ring of them we call the circuit. The waves supplied by the dynamo inevitably adjust their equilibrium of oscillatory pressures by imparting some energy to the adjacent "voussoirs" of the ether arch or complete ring, which is always in stationary and partly *progressive* vibration, which latter indicates the constant supply and absorption of wave impulses in the diverse work done.

Now, why does‡ the arc (or it might be motor) "drain" the energy in this way to itself?—or, rather, this question may now be regarded as superfluous, or a repetition. It simply absorbs more motion; the oscillatory pressure always attendant on stationary vibration (or resonance) then falls, and is supplied or renewed by the oscillating ether segments which are adjacent; and in this way they keep their equilibrium, characteristic of a circuit, and only possible in a circuit. So far without mathematical development, we may grasp at broad facts, which will doubtless be seen by all ultimately with physical powers of imagination.

In the electric light, we may figure to ourselves, then, wave motion of a long dimension *approaching* the carbons (in the main radially) and *receding* from the carbons after having been converted into *shorter* waves. The whole circuit is in pressure of electric oscillating waves, which tend to "burst" it outwards, as it were. This fact we express by saying that the "current" repels each opposite part of itself and each adjacent part of itself. It is simply the repulsion attendant on that "resonance" which we know accompanies electric effects, and which in a circuit exercises a bursting tendency. Inferentially the whole is restrained (as any form of resonance) by a rarefaction at the§ centre of all.

The wire has been described as the "sink" where the energy is wasted. In fact, the wire produces a radial progressive oscillation of the ether all about itself, as it continually absorbs, more or less, the resonant energy vibrating through its substance, which is soon made good by the dynamo, which is a mere wave-emitter introduced into the circuit, and keeping up the wave supply.

After the circuit has been fairly closed, and the equilibriated wave system (stationary and progressive) thus established, there is nothing like a "current" along the wire; but a

* This is only true, in strictness, when the circuit is uniformly circular in form.

† This form of radial (or axial) vibration was first pointed out by me in an article in *Engineering* for March 17, 1876. The significance of this form of *radial* vibration of an elastic medium does not seem to have been adequately appreciated; and one object of the present Paper is to treat of it in relation to the electric circuit. This kind of vibration (a unique condition for stability) would seem from its character to have numerous practical applications in nature; and in a future Paper I may consider some of its bearings on acoustics—air "resonance." The theory or sketch of the mechanics of the electric circuit here offered does not, of course, profess to be more than an outline or sketch—a kind of stop-gap. To say one word more about radial or axial vibration. The cylindrical air column, for instance, intercepted between two opposed metal discs, may be made to vibrate as stably as the air column in an open pipe, provided the air vibrates in such a way that all its parts move outwards from the axis joining the centres of the two opposed discs, at the same instant, and (conversely) recoil inwards simultaneously towards the axis at the backward stroke or swing. The rarefaction at the axis of the cylindrical air column makes the column recoil backwards sideways between the discs as if it were connected by radial elastic bands. Analogous considerations seem also possibly applicable to the free column of ether intercepted between two opposed vibrating molecules; indeed, the application seems difficult to limit, since no two bodies (large or small) can vibrate without intercepting a free column of the medium between them, which is open to vibrate radially.

‡ This *radial* vibration seems the *only* form that can ensure stability even approximately. Combined with the longitudinal oscillation of the segments, they form two mutually supported movements *transverse* to each other (much in correlation with the electrostatic and electro-magnetic states). Of course, we assume the ether to be to some extent compressible, and there is no real objection to this.

* No pipe actually is required here, of course, because the ether moves radially outwards (from the axis of the wire) all round the wire, *at once* or at the same instant, and so there is a balanced equilibrium of elasticity. This is doubtless one reason why *a circuit* is required for the conditions of dynamical equilibrium. Such a wave movement can conceivably extend in segmental form beyond the surface of the wire, and even to the centre of the circuit, where the waves would be reflected from each other, or all impinge together at the central point of the system.

† This special capacity of stationary vibration to draw energy to itself might be simply illustrated by imagining a line of perfectly elastic spheres in mutual collision, all the odd spheres moving simultaneously in one direction, while all the even spheres move simultaneously in the opposite direction. If, now, the end sphere be allowed to do external work by imparting motion to something, a wave will immediately run along the line of spheres, indicating the supply of energy furnished by the end spheres—equilibrium being in this way automatically restored or brought about. The end sphere (next where the work is done) thus "draws" a supply of energy to itself.

‡ A "resistance" of any kind may be regarded as a means or adaptation for communicating motion—either small scale motion ("heat") or large scale motion, commonly called mechanical motion.

§ The position of this controlling rarefaction, which forms a sort of dynamical centre of gravity, would depend, doubtless, somewhat on the position of the absorbing points (arcs, motors, &c.) in the circuit.

Digitized by Google

wave movement absorbed sideways into the wire all round,* which continues as long as the circuit is closed, of course. The chief purpose of the wire (circuit) is apparently to produce and maintain an equilibriated system of (wave) energy in the ether, which is the absolutely necessary preliminary for the constant supply of energy, the energy then choosing its own route, according to mere equilibrium of pressure of the system —in part going along the line of the circuit, and in part doubtless across, according to the position of the absorbing points for the energy (arcs, motors, &c.). The waves or impulses must evidently be more or less statical or stationary in order to constantly supply energy laterally to the wire and absorbing points (for mechanical work) in the circuit, and stationary waves imply necessarily an equilibriated system. The "current," or (more correctly speaking) wave motion enters the wire, then. in the same direction as the radiation of wasted heat leaves it. It is a mere case of the transformation of long waves into short waves—"radiant heat." Energy is said to flow along "equipotential" lines. This seems to be because a line of energy transfer (or supply) is in general a line of ether in stationary vibration. We see that it is a characteristic of stationary vibration that the pressure should be the same throughout the line (indeed, this is a self-righting adjustment). Hence it seems that a line of energy transfer must (under these conditions) abut or end at points of equipotential, *i.e.*, points of equal pressure. The flow of energy would be initiated by incipient differences of pressure, doubtless too small to be measurable, as the supply of energy is so rapid. A belt transmitting 7,000 H.P. at the velocity of light would be only under a stress of 26 to 27 grains, as may be computed. Hence the ether is a mechanism adapted for transmitting considerable quantities of energy† with very small stresses accompanying the carrying over of the energy.

We may venture here a speculative idea in relation to the electric light. In an arc light there is an ether rarefaction at the axis, about which the ether vibrates radially all round. No other vibration is possible, or even approximately stable, apparently. When the carbons are removed too far apart the arc snaps by the filling-in of the ether rarefaction, and, the equilibrium of the circuit being thus upset, the whole balanced wave system collapses (ceasing to be a circuit). At the same time the collective momentum (impulses) of the progressive waves, which tend to continue their career and bridge the interval, may constitute the induction "current" on breaking the circuit.

The sketch or mechanical outline thus offered wants filling-in as to certain points, no doubt. The hydraulic analogy, however ingeniously defended, cannot be said to hold its gronnd, and a provisional stop-gap elementarily evolved and capable of being followed easily, may be found of service, even although it does not profess to be complete, or even exact in detail. Hence‡ the above Paper.

* This lateral absorption of magnetic waves into the wire (attended by production of heat) is uniform, as we know, everywhere, no consequence how far the wire extends from the source; and this doubtless leads to the idea that it is a "current" or something flowing equally through the wire. But the apparent cause of this uniformity of absorption is the uniformity along the circuit of the magnetic waves themselves, which oscillate about the wire as an axis; and the uniformity of these waves is self-righting, as must be the case with every (more or less) stationary vibration.

† May not the polarised wave motion, or the (seemingly) molecular effect we regard as such, be something supplementary which does not substantially influence the equilibrium of the ether *en masse*?

‡ What significance has Ohm's law, it may be asked, in view of the new ideas? The law seems to apply still to transfer of energy, instead of to (as incorrectly assumed) longitudinal transfer of something called "current," along the substance of the wire. We have to regard "electricity," it would appear, as a form of energy to which the principle of equivalent convertibility, applies as to other kinds of energy. Whether the form of pulsatory wave movement about the circuit, as above gone into, would not tend to dissipate itself somewhat in the ether (in spite of the central reflection), may be a question; but it is one which does not materially affect the broad mechanical principles of the circuit and its purpose we have been considering. If the exact nature of ether waves of all kinds be in the end known, even in its minutest details, this will not apparently influence he elucidation of the object fulfilled by the circuit, and as to how it allows us to utilise the ether as a power transmitter, which is the practical point with which we are concerned. It appears, so far, a safe conclusion that radial or axial vibration is an important element in "resonance," whether of air or of ether. An assumed entirely inelastic ether is, in our view, unintelligible as regards wave effects or equilibrium at all, and we do not suppose such an idea is seriously supported.

PRIORITY IN ROTARY CURRENT MOTORS.

The following communication of Prof. A. du Bois-Reymond to the *Electrical World* of New York, of August 1st, will be read with interest:—

"With a feeling of lively satisfaction I note that you have seen fit to reproduce my Paper on rotary current in No. 26, Vol. XVII., of your esteemed journal, and I consider myself greatly flattered by the kind words of recommendation with which, in your leaderette, you invite your readers to peruse my work. But, on the other hand, I cannot help taking the liberty to state that I consider your criticism of my way of treating the priority question as unjust. I dare say you are aware that the question of who deserves the credit of being the only original inventor of electro-magnetic rotation is at present being ventilated with great ardour among the technical public all over Europe. I have followed all publications on this important subject from the beginning with great interest, though personally I have had no share whatever in the really original work done up to date. I therefore feel justified in considering myself as an outsider who can lay claim to the ability of forming an unbiassed opinion.

"Now, I personally hold that disputes on priority as far as they do not purely relate to the business side of the question only tend to pervert the historical truth. If A and B nearly simultaneously discover a new truth, why is A to be more honoured by mankind than B because he conceived his first glimmering of the new idea while walking to his office on the morning of the nth, while B only hit upon the same line of thought while smoking at his fireside after dinner of the $(n+i)$ th? We ought simply to state what A did, and what B did, and to erect statues to both in their respective native villages. But if it comes to using their names as technical terms for the new invention, one must decide which to use, and in that case I think there is no other possibility than to find out who was the first to publish, patent, or otherwise make known to reliable witnesses, if not the public at large, his new idea. May be Mr. Tesla was in the field every bit as early as Prof. Ferraris, but by some chance or other which may be and most likely is neither the fault nor the merit of either, considering that there were at the time a few thousand miles of land and sea between them, Prof. Ferraris published about six weeks before Mr. Tesla. Moreover, Prof. Ferraris published a treatise exposing theoretically nearly all the principles underlying the new system, while Mr. Tesla published a Paper mainly describing a more or less practical motor founded on the same principles, and only gave a short exposition of a part of the said principles to make his meaning clearer to his audience. Therefore, according to the accepted rule of such formalities I consider myself justified in talking of the "Ferraris principle" and of the "Tesla motor," because everybody who is acquainted with the scientific etiquette knows perfectly well that by this mode of expression I do not offer incense to the one and contempt to the other, but simply mean that according to my knowledge of history the one has been the first to *publish* the principles and the other the first to patent the motor. You might contend that in order to construct a motor a man must be master of its principles and not *vice versâ*; therefore Mr. Tesla by publicly describing his motor has proved that he possessed the principles before Prof. Ferraris' publication. This I will freely admit, though such a contention is certainly open to controversy; but then that would only be one reason more to hold up Prof. Ferraris' merit beside Mr. Tesla's, because even the most ferocious Teslaite must allow that there is merit worth mentioning in having published the said principles. Now, by talking of the Tesla motor we do not detract in the least from Mr. Tesla's merit, because, having constructed his motor, everybody will credit him with understanding the underlying principles, and everybody who is acquainted with the chronology of the case will easily infer that he must have evolved those principles without the help of Prof. Ferraris' publication, which could hardly have reached him before he filed his first patent. On the other hand, if we would neglect to mention Prof. Ferraris as the first pub-

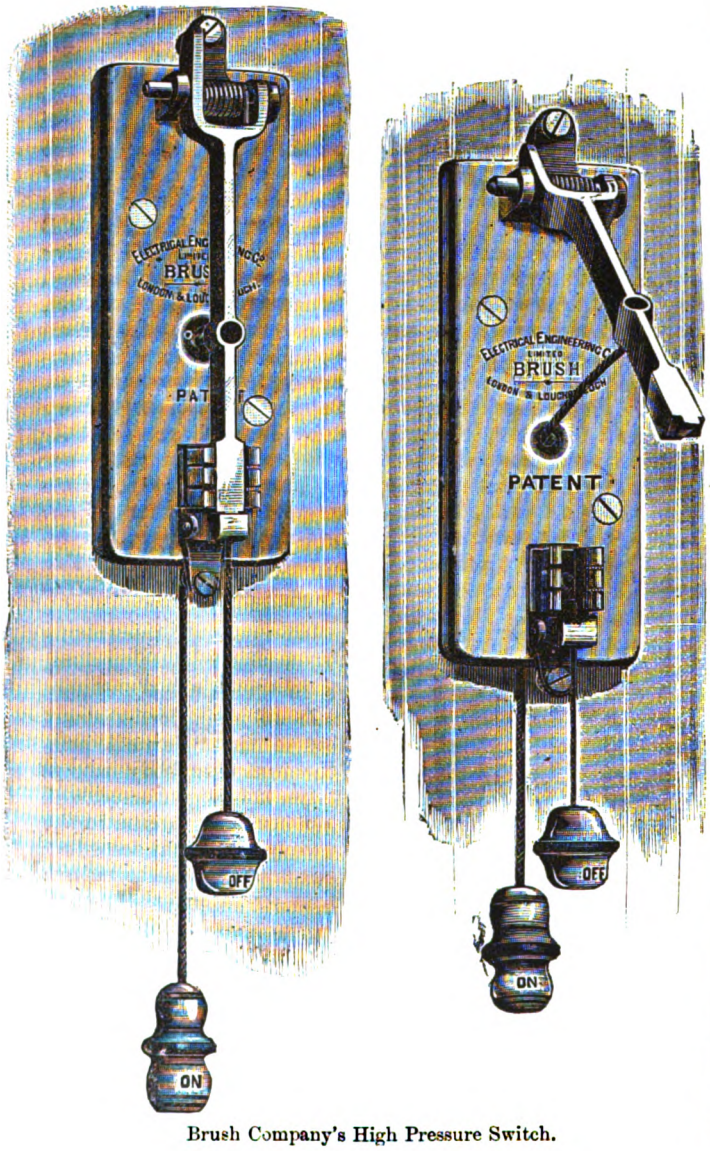
Digitized by Google

lisher of the said principles, we would ignore his merit altogether.

I must apologise for having suffered myself to be drawn out to such a length by your casual remark, but, considering the great interest brought forward *in re* priority of electromagnetic rotation in this country, I hope I may find indulgence.

THE BRUSH COMPANY'S HIGH PRESSURE SWITCH.

In the numerous switches which are now offered for use with high pressure circuits, the safety of the operator is generally provided for by long and well insulated handles. Sometimes a cover is relied upon to keep his hands away from the bare metal, and a kind of kilt has been added in other cases to guard against an accidental slip of the hand. At Deptford, and on other parts of the circuits of that station, Brobdignagian "jack-knives" are employed, while the Thomson-Houston Company use a loose handle and a spring catch, which bears no resemblance to a switch.



Brush Company's High Pressure Switch.

The Brush Company have for some time been using a switch which has much to recommend it, not the least important feature being the perfect safety from accidental contact with the switch itself. As all switches ought to be, this one is constructed entirely of porcelain and metal. The two illustrations show very clearly the action of the parts. A lever is hinged with a good wide hinge, allowing no side shake, and wh ch is provided with a strong spiral spring tending to open the circuit. The lever can be pulled down by a stout cord, to which is attached a porcelain knob, marked *on*. When this is pulled down as far as it will go, the lever is jammed between two spring contacts, and is caught by a spring "trigger." The release is simply effected by means of another cord with a porcelain knob, marked *off*, and this pulls back the trigger and allows the spiral spring to throw up the lever, making a long and a quick break. There is some prejudice against the use of springs, and this has no doubt arisen from the use of poor material in cheap switches, and from bad designing, a common fault being that the spring acts in a very indirect manner and with considerable friction. For the moderate currents commonly used in alternate current work this switch appears to be excellently adapted. There is no necessity for the operator's hands to come anywhere near the metal, and the break is bound to be rapid and complete.

THE SWINBURNE NON-INDUCTIVE WATTMETER.

Messrs. Swinburne and Co. have recently brought out a wattmeter designed to avoid the errors due to the appreciable time constant usually possessed by the fine-wire circuit of such instruments. The moving coil contains but few turns, and these are wound on a light mica former. The coil is held by top and bottom stretched wires. External resistances are supplied, wound with the alternate layers right and left handed, so that the time-constant of the fine-wire circuit is made sensibly equal to zero. Readings are taken by means of a torsion head in the usual way; but for measurements of

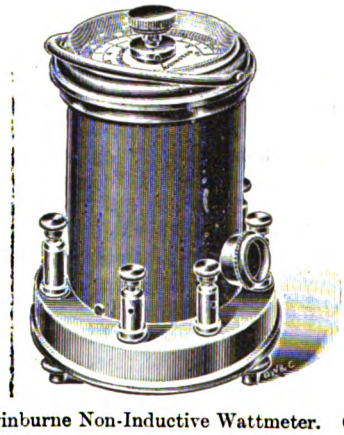


Fig. 1.—Swinburne Non-Inductive Wattmeter. General View.

minute powers, such as hundredths of a watt, a mirror is used. These wattmeters are wound to suit any range from 3,000 volts and from 25 amperes downwards. The makers claim that they read accurately on non-inductive resistances, and on inductive circuits in which the product of the pressure and current is 50 times the real power.

A general view of the instrument is given in Fig. 1, and the construction of the wattmeter is more clearly shown in Fig. 2. Two cast gun-metal columns carry the fixed coils; one of these coils is removed, showing the cylindrical mica former mounted on an ivory spindle. This spindle passes through top and bottom guides, and the suspension is kept taut by a spring at the bottom. The instrument can be sent about without slackening the suspension, as the coil is very tight, and it cannot move far sideways. The zero index stretches over a mark on a slanting plane. This is visible through a hole in the dial on looking down on the instrument, being lighted by a circular window in the case. A plummet is also arranged for levelling, but is taken off in our illustration to admit of a clearer view. The current coils can be easily changed without interfering with the suspended system. This is important, as one set of coils only suits one range. For instance, a voltmeter or ampere meter for 100 volts, or 100 amperes, is always ready, but a wattmeter for 100 watts may be called on to read with 100 volts and 1 ampere, 100 amperes and 1 volt, or any other pair of factors. The most convenient range for a wattmeter is 100 volts, and any current up to 20 or 30 amperes. It is then available for measuring transformer efficiencies by measuring

Digitized by Google

the power going in on the 100 volt side, when the transformer is used to transform up at no load. To measure the primary power needs a resistance of some 80,000 ohms in the 2,000 volt circuit, and this means 40 watts, or 80, which must be allowed for if the instrument is coupled up, so that the fine wire current also flows in the current coils.

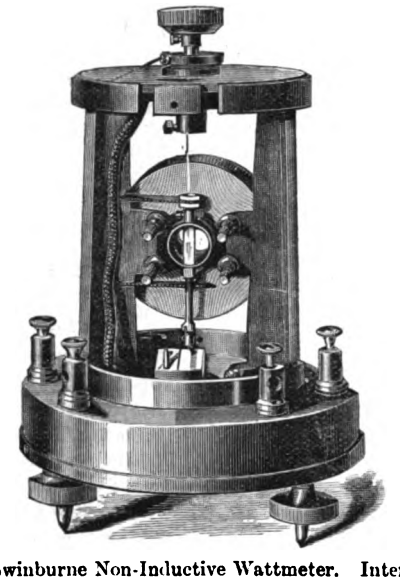

FIG. 2.—Swinburne Non-Inductive Wattmeter. Interior View.

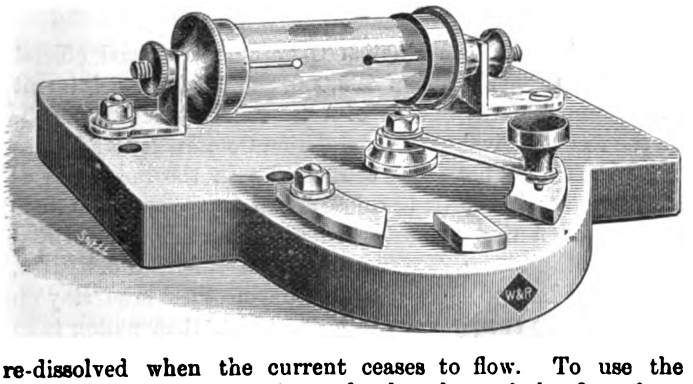
Mr. Swinburne recently described an electrometer which reads power directly, which, though it does the work of the three voltmeters discussed by Messrs. Ayrton, Sumpner, and Swinburne soon after, unfortunately needs resistances. Dr. Fleming has enormously improved the three-instrument method by substituting ampere meters, and we thus have unassailable means of verifying the wattmeter.

WOODHOUSE AND RAWSON EARTH DETECTOR.

Our illustration shows an instrument designed with a view of placing in the hands of householders and others using the electric light a ready means of detecting any leak or fault which may develop itself in the insulation of the installation. On a polished slate base is mounted a small glass tube, one end of which is connected to some good earth, while the other may be connected at will through a switch with either lead. The tube is filled with a liquid which is decomposed when a current is passed through it, the positive electrode becoming covered with a reddish brown deposit, which is slowly



re-dissolved when the current ceases to flow. To use the instrument, connection is made by the switch, first from earth to one lead of the installation, and then from earth to the other. If the insulation of either lead has become defective, it will be shown by the discoloration produced. This instrument is not intended as a substitute to the electrician for quantitative measurements, but it may be found useful in ascertaining, from time to time, in a simple manner, whether the insulation of house circuits is in a perfect condition or not. The detector is manufactured by Messrs. Woodhouse and Rawson.

INSTITUTION OF ELECTRICAL ENGINEERS.

At a special general meeting of members only of the Institution of Electrical Engineers, held yesterday, at the offices of the Institution, the subjoined resolution was unanimously passed:—

RESOLUTION.

"That Nos. 22, 23, 25, 26, and 27 of the Articles of Association be altered so as to read as follows:—

Article 22. "Every Member elected before the 31st of December, 1891, shall pay to the Institution an entrance fee of Two Guineas on his election; or, if elected after the said date, an entrance fee of Three Pounds. Every Foreign Member shall pay an entrance fee of One Guinea. Every Associate, if elected before the 31st of December, 1891, shall pay an entrance fee of One Guinea; or, if elected after the said date, One Pound Ten Shillings. Every Associate transferred to the Class of Members before the 31st of December, 1891, shall pay a further entrance fee of One Guinea; or, if transferred after the said date, a further entranee fee of One Pound Ten Shillings. Every Student transferred to the Class of Associates shall pay an entrance fee of One Guinea."

Article 23. "Except as hereinafter provided, every Member elected before the 31st December, 1891, shall contribute annually to the Institution the sum of Two Guineas; or, if elected after the said date, the sum of Three Pounds. Every Associate elected before the 31st December, 1891, shall contribute annually the sum of One Guinea; or, if elected after the said date, the sum of One Pound Ten Shillings. Every Foreign Member shall contribute annually the sum of One Pound, and every Student Half a Guinea. Any Member or Associate residing abroad, or absent from the United Kingdom for nine months in any year, and giving previous notice in writing to the Secretary of his intended absence, shall contribute annually the sum of One Pound."

Article 25. "Any member elected before the 31st December, 1891, may compound for his annual subscription by the payment to the Institution in one sum of Twenty-one Pounds if resident in the United Kingdom, or, if resident abroad, by the payment in one sum of Ten Pounds. Any Member elected after the said date may compound by the payment in one sum of Twenty-five Pounds if resident in the United Kingdom, or, if resident abroad, by the payment in one sum of Ten Pounds. Any Associate elected before the 31st December, 1891, may compound for his annual subscription by the payment in one sum of Ten Pounds; or, if elected after the said date, by the payment in one sum of Twelve Pounds Ten Shillings if resident in the United Kingdom, or of Ten Pounds if resident abroad. Any Foreign Member may similarly compound by the payment in one sum of Ten Pounds. Any Foreign Member, or any Member who, as residing abroad, has compounded by payment of Ten Pounds, shall, if he come to reside in the United Kingdom, and if he was elected before the 31st December, 1891, pay either an additional composition of Eleven Pounds or an annual subscription of One Guinea. If he was elected after the said date, he shall pay either an additional composition of Fifteen Pounds or an annual subscription of Two Pounds. Any Associate elected after December 31st, 1891, who, as residing abroad, has compounded by the Payment of Ten Pounds, shall, if he comes to reside in the United Kingdon, pay either an additional composition of Two Pounds Ten Shillings or an annual subscription of Ten Shillings.

"All such compositions shall be invested, and the interest alone shall be appropriated to the current expenditure of the Institution, at the direction of the Council.

"Any donations in aid of the funds of the Institution may be accepted by the Council and Treasurer."

Article 26. "A Foreign Member who has not compounded shall, if he come to reside in the United Kingdom, pay an annual subscription of Two Guineas if he was elected before the 31st December, 1891, or of Three Pounds if he was elected after the said date."

Article 27. "An Associate resident in the United Kingdom who has compounded by payment of Ten Pounds shall, if transferred to the class of Members before the 31st December, 1891, pay either an additional composition of Eleven Pounds or an annual subscription of One Guinea. If transferred after the said date, he shall pay either an additional composition of Fifteen Pounds or an annual subscription of Two Pounds. An Associate resident in the United Kingdom who has not compounded shall, if transferred to the class of Members before the 31st December, 1891, pay an annual subscription of Two Guineas; or, if transferred after the said date, an annual subscription of Three Pounds."

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements should be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL PREPAID ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1891 Edition, published on the 23rd February, 1891, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with well-written Biographical Notices of leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1891 should be ordered at once. Price 5s., post free 5s. 9d. Abroad postage extra. Prospectuses free.

ELECTRICAL BOOKS AND PUBLICATIONS

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. Vol. I. Price 7s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Vol. I. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

Several Further Volumes in Active Preparation.

NOW READY, IN TWO VOLUMES.

"THE ELECTRICIAN" PRIMERS.

Fully Illustrated.

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s 9d. each. Single Primers, 9d., post free, 9½d. Abroad postage extra.

SPECIAL NOTICE.

With next week's number of "THE ELECTRICIAN" we shall issue a fine Steel-Plate Portrait of Professor von Helmholtz.

STEEL-PLATE PORTRAITS

Of W. H. Preece, F.R.S.; Michael Faraday; Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Past-President of the Institution of Electrical Engineers); C. H. B. Patey, C.B. (Late Secretary of Telegraphs, G.P.O.); Dr. John Hopkinson, F.R.S. (Past-President of the Institution of Electrical Engineers); Dr. Oliver J. Lodge, F.R.S., and Prof. William Crookes, F.R.S. (President of the Institution of Electrical Engineers), have been issued as Supplements to "THE ELECTRICIAN." *A few Copies of these admirably-executed Steel Engravings can be supplied, price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, post free, 4s. 6d.*

THE CHICAGO EXHIBITION.

The decision of the English Government to lend official support by voting a grant of £25,000, and by the appointment of the Council of the Society of Arts as a Royal Commission, and the recent arrival of the Exhibition Commissioners in this country, warn us that those connected with the industries of Great Britain will shortly be called upon to make up their minds whether or not these industries shall be worthily represented in 1893 at the Chicago Exhibition. The American delegates, it must be admitted, have displayed during their brief stay on our shores the energy and push for which their nation is so justly famed. They have indefatigably interviewed and been interviewed, dined and been dined. No one in the remotest degree likely to contribute to the success of the Exhibition, from the Queen, Lord Salisbury, and the Secretary of State for India, down to the Lord Mayor and the London Chamber of Commerce, has escaped their eagle eye; and at the present moment the same process of buttonholing is being vigorously carried out on the Continent. It is needless to say that the delegates have everywhere been cordially greeted, and have received profuse promises of official support. The present

Digitized by Google

inhabitants of the United States are proverbially smart, but it must tax this gift somewhat severely to muster up a valid reason either sentimental or based on mere business considerations, why English traders, as a body, should take any enthusiastic interest in the proposed "World's Fair."

The trade of this country with the United States is undoubtedly large, larger indeed than that with any other single country in the world, yet it forms but a small proportion of our trade with the entire world. According to the latest statistics available England's total trade with the world amounts, in round figures, to £864,000,000, of which our trade with the United States forms but £121,000,000, or 14 per cent. A trade of this volume is certainly not a negligible quantity, but, considering its nature, the fixed determination of one of the parties concerned to reduce it to a minimum, and the enormous distance between London and Chicago, it is difficult to see what English commerce, as a whole, has to gain by lavish exhibiting, although particular industries will probably find sufficient incentives to spend money in this direction. And as to sentimental considerations, which indeed come into play but weakly in such matters, they are not very apparent. It is to be doubted whether the quincentary of Columbus's arrival in the West Indies is a sufficiently powerful lever to move Englishmen, with their "inborn conservatism," to despatch goods several thousands of miles across land and water to encounter, on their arrival, the chilly blast of the McKinley tariff. The English Government thought fit to withhold its official support from the Paris Exhibition of 1889, because it celebrated the centary of an event which, although stirring, was one about which there is a wide divergence of opinion. In spite of the absence of official sanction, English exhibitors mustered in force. Their interests lay that way, and Paris was not as many hundreds of miles away as Chicago is thousands. Official support and the efforts of the Royal Commission and the Exhibition Commissioners notwithstanding, we venture to predict that English exhibitors will not be present in full force at Chicago. Three inducements are necessary to ensure their presence—namely, self-interest, proximity, and a spark of enthusiasm; and it is these very desiderata that are conspicuous by their absence.

However convincing the arguments for holding aloof from the 1893 Exhibition may be when applied to the industries of England as a whole, they apply with redoubled force to the electrical industry. While no good Englishman can be got to admit for one moment that American electrical engineers turn out such efficient plant as we do, there is no gainsaying the fact that they turn out considerably more. Until a few years ago the English electrical engineer spent his enforced leisure in bringing dynamo and engine design to a science. Meanwhile across the ocean there was an immediate and large demand; dynamos had to be constructed somehow, and were generally constructed anyhow. Just at the time when we were celebrating the passing of that act of reparation known to lawyers as the Electric Lighting Act (1882) Amendment, our American friends, having solved the problem of electric lighting after their kind, were turning their energies to electric traction, in which branch of applied electricity there seems to be every chance of history repeating itself. The net result is that the Americans have evolved, under the conditions peculiar to them, several systems which meet the exigencies of transatlantic work; and they can now get along very well to their own satisfaction without us. Even if Free Trade prevailed between the two countries we doubt whether the United States would offer a very favourable market to English electrical apparatus, and with a prohibitory tariff in full swing, the attempt to force a market by dint of superior quality is hopeless. In Germany, electric lighting is fairly prosperous and progressive, import duties, though high, are not prohibitive, and German engineers can boast neither of the experience nor of the ingenuity of their American brethren; yet, in spite of the great exertions of the promoters, the title is, perhaps, the most international feature of the Frankfort Exhibition.

Though lacking in "internationality," the Chicago Exhibition will, it may be safely said, prove eminently successful as a big national show. To doubt it would be to indict a whole people, and that we have it on good authority is impossible. With its vast area and population, the diversity of its climate and products, and the ingenuity and energy characteristic of the race, the people of the United States should be able to get together a "fair" which will astonish the world, and in this "fair" no department will be of greater interest than that devoted to electricity. Englishmen will there be able to see the many strange things in electricity that America has brought forth during the past ten years. There will be much to learn, and, perhaps, something to unlearn, and a harvest of knowledge will be reaped in a few hours which, without the Exhibition, would require months of weary journeying in "palace cars." English electrical engineers may well wish success to the Exhibition, though they fail to discover valid reasons for taking part in it.

THE CONTOUR OF SOME COSMICAL VARIATIONS AND THEIR APPARENT TEACHING.

BY ALEX. J. S. ADAMS.

In connection with cosmical science, there is, perhaps, no branch more beset by difficulty than that of the daily variations in the earth's electricity and magnetism due to the ceaseless interactions of separate self-varying forces; nor in its connection is it an easy task to demonstrate to other minds effects which the familiarity of long study may have made clear to one's own.

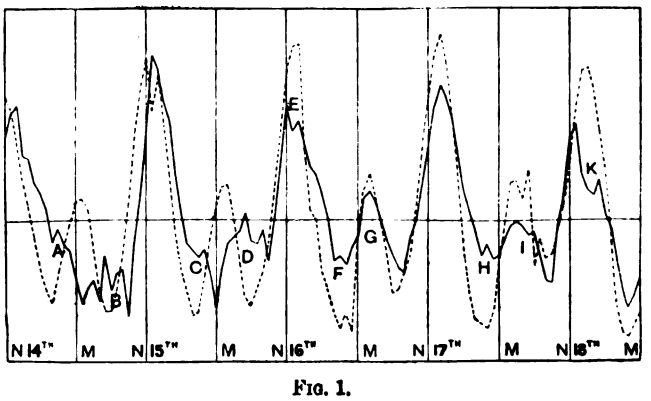

Fig. 1.

——— Declination. ..... Derived.
January, 1884.

In respect of the earth's magnetic and electric variations, the attempt is, however, here made if only that the point of view from which the subject has been studied by ourselves may become plain to other students; and that the subject may obtain greater prominence than it at present enjoys. It is not here proposed to offer an opinion upon the earth's *directive* influence, nor in respect of the *fact* of the declination; we seek only to bring under notice certain features of variation contour, aud to suggest truths which appear to us to underlie them.

Our first example of cosmical variation is given in the diagram (Fig. 1), in the continuous line curve, where we have the daily variation of magnetic declination as found at the Royal Observatory, Greenwich, during the 14th to 18th January, 1884. The letters N and M indicate noon and midnight, and are separated by their intervening hours.

Digitized by Google

Now, the first feature we notice about these curves is the similarity of one day with another. In the second place, we observe in each day a following of the sun's movement relative to the horizon, insomuch that whilst the curve is above the mean line during the daytime, it is generally below the mean line during the night hours. Thirdly, we notice that the otherwise smooth curve is frequently broken up, as at A, B, C, &c., especially during the night periods; and consequent upon which there exists a continuous tendency towards a system of daily double change, as instanced at B, D, G and I. In the

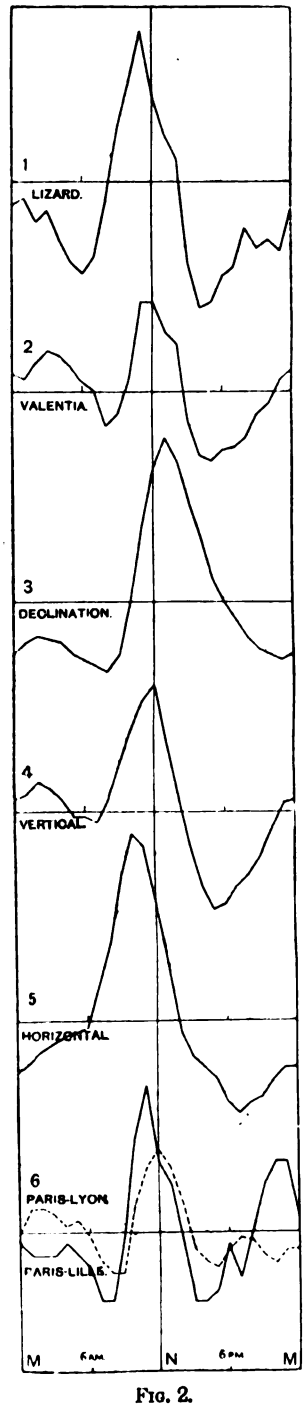

FIG. 2.

fourth place, we notice that superposed upon the general sun-following—or diurnal inequality—there is a peculiar flattening effect during the night periods, as against a marked peaking at noontide. Thus, in respect of the magnetic declination, daily variation, we have these four features:—(1) Daily similarity; (2) Daily sun-following; (3) Double daily change; (4) Noontide peaking.

But we have yet another feature to consider, namely, the possible similarity of daily contour between the variations of the different elements of the magnetic and electric phenomena. In diagram Fig. 2 we present, for comparison, curves of diurnal variation for the various elements, and which are consecutively as follows:—(1) The mean daily earth-current variation for 30 days, as observed at the Lizard Office upon the Lizard-Bilbao cable; length, 480 nauts.* (2) The mean daily variation of 78 days' earth-current change, as observed upon a submarine cable, extending 1,850 nauts, from Valentia into the Atlantic.§ (3) The mean diurnal variation in magnetic declination for every day of the year 1889, as observed at the Royal Observatory, Greenwich.† (4) The same of the magnetic vertical force.† (5) The same of the magnetic horizontal force.† (6) Examples of diurnal earth-current variations, as observed upon the Paris-Lilles subterranean conductor for March 13th, and Paris-Lyon for October 30, 1884.‡

The evidence here afforded of accord between the magnetic and electric daily variations is sufficiently demonstrative of the fact that in each case the four laws already alluded to strictly obtain. Moreover, it is here clear that in analysing the variation of one element, we to a large extent analyse the others.

For the purpose of analysis we select a series of earth-current variations, as observed upon one of the Atlantic cables by Mr. James Graves,§ and we do this because of the large extent of globe-surface embraced by the cable; and because of the sensitiveness of the apparatus used. Examine the example of this Atlantic earth-current variation for March 8, 9, 10, 1871, as shown in diagram Fig. 3 (*dotted* line I) where also N and M represent noon and midnight. The daily sun-following, and the tendency to a diurnal double change, are clearly depicted.

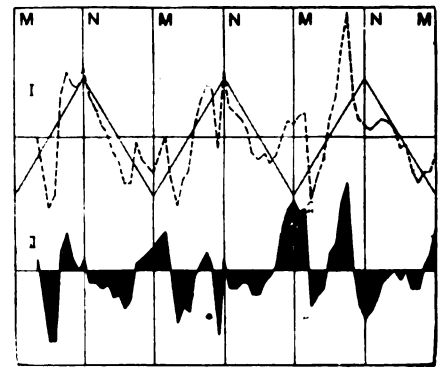

FIG. 3.—Valentia. Diurnal Tides.

The noon peaking is not well developed, but we should not fall into the error of supposing that because this last is inconspicuous the whole variation is necessarily separate and different, because the direction occupied by the electric conductor and the angle at which the magnetic measurements are taken would seem to materially modify the contour of the final result.

Let us more closely question these curves. To do so we draw the ideal solar-inequality line diagonally from N to M, and from M to N, and we then measure the dotted curve from it. The ideal solar line is now brought down and straightened (Fig. 3, II), to form a new *mean*, and the results of our measurements are stated in curve, proportionately above and below it. This new curve—darkened to render the result more conspicuous—distinctly tells us that whereas we had in curve I a diurnal sun-following, distorted in places, we now have in curve II., by the elimination of the inequality effect, a system of self-contained double variation not unlike that of the ocean tides, and thus the distortions to the solar-inequality curve are largely explained.

But in connection with this double motion, we have to ask, "Is it a true tide?" that is to say, "Is it some gravitation effect, and is it of solar or lunar origin?" Both queries may, perhaps, be answered by learning whether this earth current has a periodic movement coinciding with new and full moon; in other words, with the ocean, spring, and neap tides. In diagram, Fig. 4, the total daily variation for each day of 78 days upon

* Kindly placed at our disposal by Sir James Anderson.

Digitized by Google

this Atlantic cable is reduced by a constant, and the result thrown into curve. The lines F and N denote the times of full and new moon during the period of observation.

The outcome of our inquiry is most clear in exhibiting a distinct succession of electric spring and neap tides, which certify that the double change shown in curve II. (Fig. 3) is a true tide, and by inference due to the presence of both a solar and a lunar tidal effect.

In respect of this Atlantic cable, therefore, we reach definite ground, namely, that the earth current daily variation is built up of at least three separate forces—a solar-inequality, which we may term T 1, a lunar-diurnal double tide, T 2, and a solar-diurnal double tide, T 3. But we have yet to see how far this building up by the three T's obtains in respect of other earth-current conductors, and the magnetic elements. And, first, in support of the contention that the same law applies to them all, we have the practical similarity of contour exhibited in the curves of Fig. 2, and by which we learn that although the diurnal variation may exhibit an endless variety of modifications, the diurnal "characteristic," as illustrated by the four laws already enunciated lies at the base of them all. And, second, there is the fact—not demonstrated here owing to want of space—that the feature of springs and neaps obtains also in connection with the earth-current records of the Royal Observatory, Greenwich, aerial conductor; with those of a London-Cardiff post office aerial conductor; with those of the Paris-Lille, the Paris-Lyon, and other subterranean conductors; and in respect of the three magnetic elements. These spring and neap effects combat once and for all any idea of causation in submarine cables by the movement of tidal waters. Nevertheless, the spring and neap effects are as much interwoven with other phases as is the diurnal solar-inequality. For instance, there is exhibited—especially in the magnetic vertical force variation—an unmistakable lunar-inequality effect, and careful inquiry will frequently elicit the result of the rolling, one over the other, of the inequality and spring-neap forces. An interaction of this kind is presented to us by a discussion of the Greenwich vertical force variations for April to December, 1884, as illustrated in diagram (Fig. 5). Following the curve of daily variation there shown, we find that the new and full moon periods M and F are clearly *single*, that is to say, are lunar-inequality movements, accompanied by interruptions caused probably by the spring and neap effects K and K. F_2, N_2 are *mixed*, insomuch that little can be made of them; a mixing, by the way, which seems to have periods of recurrence of about three or four months. F_3, N_3, F_4, N_4, are clearly inequality effects, whereas F_5, N_5, F_6, N_6, are spring and neaps. At N_6, N_7, the curve is again mixed, but thence resolves itself into inequality.

We now reach another definite point for consideration, and it is this:—"As T^2 and T^3 are tidal, with daily double motions, may not T^1 be tidal also, notwithstanding its single movement?" Now, so far as we may judge, the effect of disturbed gravitation is the formation of equipoise in the form of an ellipsoid, whereby, as an example, we derive our ocean double tide. In following this idea with respect to these electric and magnetic variations, we are led to the conclusion that in some way or another those phenomena conform to the ellipsoidial law, and that, as a consequence, our globe will revolve between two centres of force, as illustrated in Fig. 6.

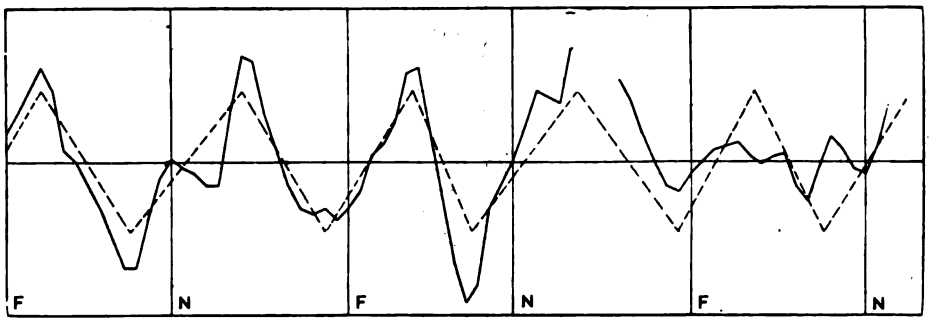

FIG. 4.—Valentia. Earth Current, March 7 to May 27, 1871. Springs and Neaps.

In this diagram, the globe represented by the inner circle is revolving between the two centres of force S and S. The effect of S and S will diminish in all directions; and the spot upon the earth's surface—here represented by the middle circle—will, in revolving from 6 a.m to 6 p.m., and from 6 p.m. to 6 a.m., strike the single line radials from S and S at various points, the values of which are stated by figures underlined. In like manner, a similar treatment of T^2, where S and S are greater than in T^3 as 5 is to 2, and where the elliptical eccentricity is proportionately extended, gives the following hourly values, counting from 6 a.m. to 6 p.m. inclusive:—0·26, 56, 84, 110, 126, 133, 126, 110, 64, 56, 26, 0. Of course, similar values hold good for the other half of the day. In applying this treatment to T^1, it must be on the assumption that whereas the ellipse in the case of semi-solids and liquids will be equally distributed as regards the globe, as in Fig. 6, in the case of more elastic material, such as occupy the far higher regions of our atmosphere, the sun's attraction will so overpower that of the earth as to pull the atmospheric ellipse away towards itself. Thus, whilst the cosmic operation is one and the same for the three T's, the actual result in the case of T^1 will, of necessity, be a diurnal single movement. Granting T^1 a maximum S of 500, at a distance twice that of T^2, we obtain the following figures, counting from midnight to noon inclusively:—0, 0, 0, 10, 25, 47, 73, 100, 127, 157, 186, 208, 214. The same holding inversely for the other half of the day.

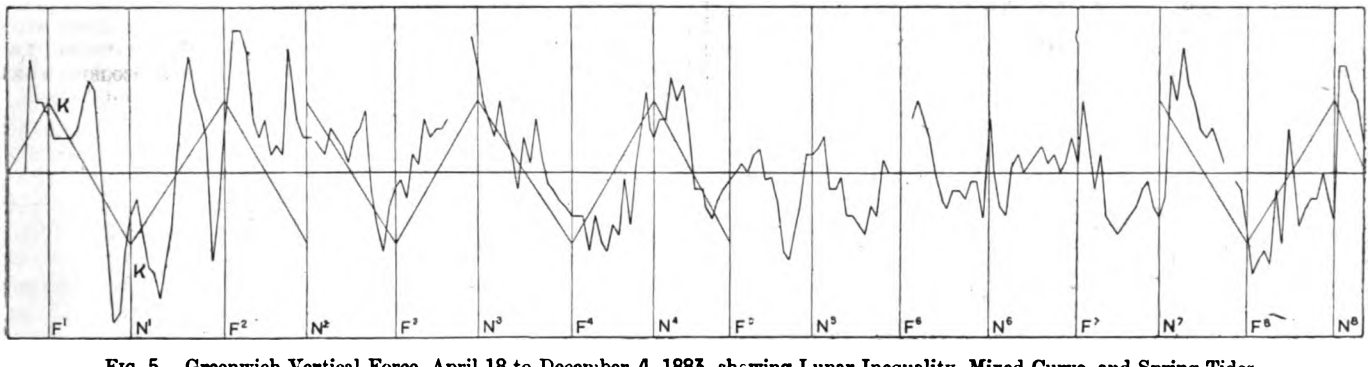

FIG. 5.—Greenwich Vertical Force, April 18 to December 4, 1883, showing Lunar Inequality, Mixed Curve, and Spring Tides.

Digitized by Google

The mean value of the forces derived in this way over a period of several days, always allowing for lunar-lag, is shown by the dotted curve in Fig. 1, and when it is remembered that the effect of lunar-inequality, declination, and orbital variation, and the enormous displacement caused by priming are neglected, the result may be considered as closely approximating actual to the variations we have had under review.

It may be objected that the lunar-inequality effect, instead of being greater than the solar-inequality, is, in reality, much less; but it may be replied that the rarefying influence of the sun's heat upon the atmosphere may indirectly augment the in equality in its case.

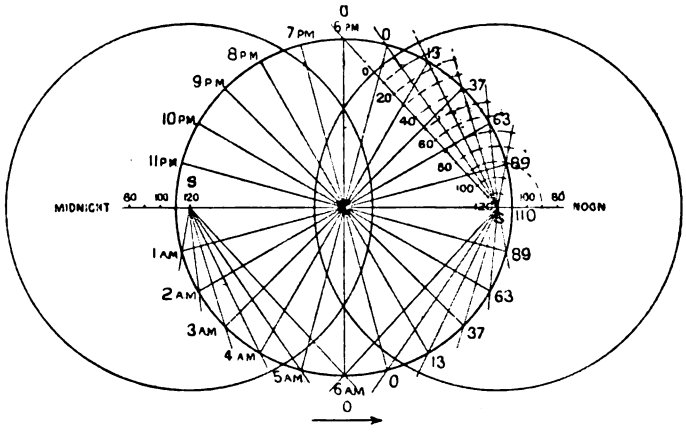

FIG. 6.

In respect of the view here advanced further evidence could be adduced, and we hope to widen the subject in a future Paper.

THE ELECTRIC TRANSMISSION OF POWER.*

BY GISBERT KAPP.

LECTURE III.

(Continued from page 396.)

As an example of a large modern transmission plant, I select, for illustration, that erected a few months ago for the Schaffhausen Spinning Mills. This example is not only interesting on account of its magnitude, but because it has been planted, so to say, into the very stronghold of rope transmission, namely, at the Falls of the Rhine, where the last generation of Swiss engineers carried out such admirable work in teledynamic transmission that the present generation can only copy, but cannot improve upon it.

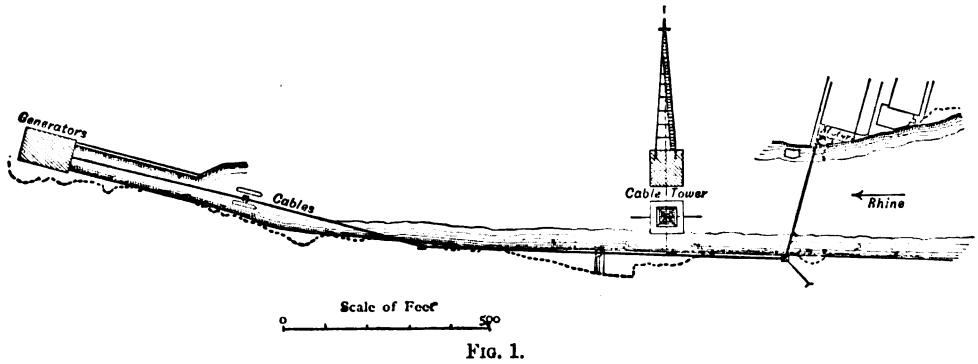

FIG. 1.

And the grand example set by Redtenbacher, Amsler, and others, on the Rhine has, as a matter of fact, been largely copied at other places. There is hardly a large engineering works in Switzerland or the South of Germany where rope transmission in some form or other will not be found, but the best days of this system are passed. Till recently, rope transmission held the field absolutely, not because it was perfect, but because there was nothing better. Now, however, we have something better in electric transmission, and the flying ropes are being steadily replaced by the electric conductors. In the first place, the capacity of teledynamic transmission to deal with large powers is limited. During last year, the Niagara Commission inspected a large number of plants in Europe, and came to the conclusion that 330 H.P. is the very utmost which can be dealt with by a single rope, so that above this power we must employ more ropes with a corresponding complication in the gear. I need hardly say that no such limit exists in electric transmission. But there are other difficulties in connection with ropes. They wear out very fast, their support at the translating stations on the line requires the erection of very heavy and costly structures, and they are largely influenced by climatic changes, causing excessive strains at some times, and slipping at others. These considerations have induced the managers of the Schaffhausen Spinning Mills to adopt electric transmission in the very spot where rope transmission, in years gone by, has received its most perfect development possible.

The situation of the works is shown on the diagram (Fig. 1). The spinning mills are on one side, and the generating station is on the other side of the river, the distance between the two being about 750 yards. In the generating station there is room for five 350 H.P. turbines, of which four are now in place, but of these only two are as yet used in connection with the electric power transmission I am about to describe. The power of these turbines is sold to the Spinning Company at the rate of £2. 16s. per annual horse-power taken off the rope pulleys (Fig. 2). The turbines are horizontal wheels, and their vertical axes are geared by bevil wheels with the rope pulleys, by which motion is conveyed through cotton ropes to the two generating dynamos. The latter are six-pole machines, each designed for an output of 330 amperes at 624 volts, and in regular work these machines are coupled parallel. The machines, and, in fact, the whole installation, with the exception of the hydraulic works, has been designed by Mr. Brown, to whom I am indebted for the particulars I now bring before you. The electrical part of the plant was made and erected by the Oerlikon Engineering Works. The line consists of four cables (each having an area of ·437 of a square inch), and is supported at four intermediate points, besides the supports at the terminuses. One of the intermediate supports is the old turbine house, which, in former times, was used in connection with the wire rope transmission; the others are towers of iron framework, 46ft. high, one of which is shown to a larger scale in Fig. 1. The span where the line crosses the river is 330ft., and where it passes along the shore of the river the span is 430ft.

You may imagine that the proper support and insulation of cables of that size, and with so long a span, is a matter of considerable difficulty. The use of glass or earthenware insulators on a stalk, as employed for the support of telegraph lines and other light wires, is, of course, out of the question. We must have something very much more substantial, and this has been provided in the manner shown in Fig. 5 (p. 418). Near the top of each post there are bolted to the iron framework four of the boxes shown on this diagram—one for each line of cables. The inner box serves as a kind of junction or connecting piece between the cable ends, which are opened out, as shown. Molten zinc is then run in, and surrounds every single wire, thus making a perfect electrical joint; whilst at the same time, the strain is divided between all the wires in the most even way possible. The inner box is surrounded by an outer box, and the intervening space is cast out with sulphur, which is an excellent insulating material, and, applied in this way, of sufficient mechanical strength to resist the large forces involved in the supporting of these heavy cables.

In mountainous countries, where thunderstorms are frequent and violent, the protection of lines from lightning strokes is a matter that must not be overlooked. The line I am describing is protected in a two-fold manner. In the first place, there is stretched over the four electric cables a steel wire rope, passing right over the supports, and in good electric connection with their iron framework, and therefore with earth. The object of this arrangement is to act as an ordinary lightning protector, on the supposition that a lightning flash will rather go to earth by way of the steel cable and one of the towers that run along the electric line. But light-

* Cantor Lectures delivered before the Society of Arts, February and March, 1891.

Digitized by Google

ning flashes are sometimes very erratic, as was shown experimentally in this very room, in the admirable "Mann Lectures," which Prof. Lodge delivered before this Society in 1888. It is, therefore, also necessary to make provision for flashes which will, for some reason or other, stray away from the direct path provided for them; and this has been done in the Schaffhausen installation, by the employment of lightning arresters at both terminal stations. At each station there are four lightning arresters, one for each cable. They consist of a pair of toothed plates, of which, however, only one is fixed, the other being movable. When a flash strikes one cable only, it goes to earth by the corresponding plates, and no further damage is done.

Fig. 4 shows a drawing of these generators. Fig. 3 is a drawing of the twin motor, which receives the bulk of the power at the spinning mills, whilst the remainder is taken up by a couple of two-pole motors, placed in other parts of the mills. These are not shown on the diagrams, as they are of the ordinary design, with which you are already familiar. The twin motor is rated at 380, and each of the single motors at 60 H.P., making in all 500 net brake H.P. delivered to the mill shafting. The coupling between the motors and the mill shafting is by cotton ropes, as shown in Fig. 3, the arrangement chosen having the advantage that very little side strain is thrown upon the motor bearings, owing to the ropes pulling opposite ways.

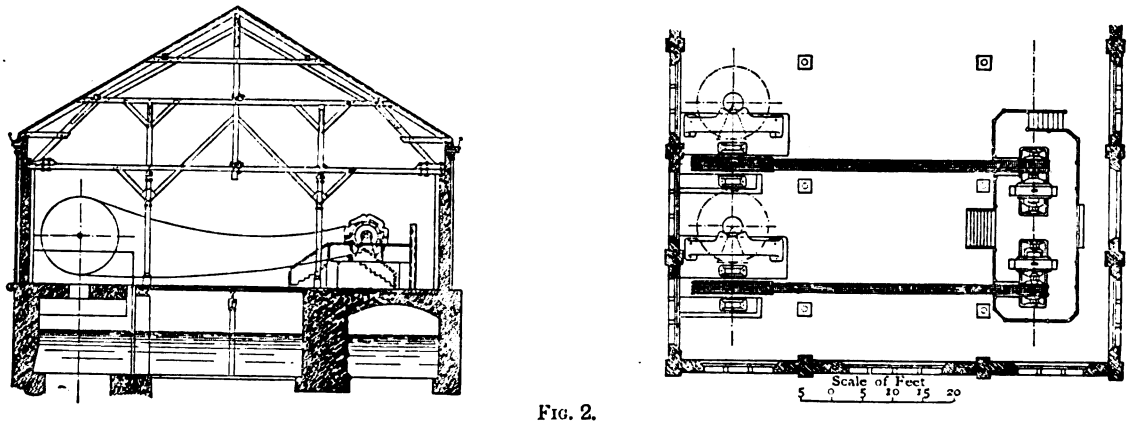

FIG. 2.

Should, however, both a positive and a negative cable be struck at the same time, then the arc set up between the plates by the passage of the lightning flash provides an easy path for the passage of the power current also; in other words, the generator will be short-circuited. The object of making one of the plates movable is to

An interesting and novel feature of the plant is the arrangement adopted for starting gradually, and yet without the use of resistance. In my experiments last week I used current delivered at constant pressure; and, to start the motor gradually, and prevent sparking at the commutator, I was obliged to insert into the armature circuit a

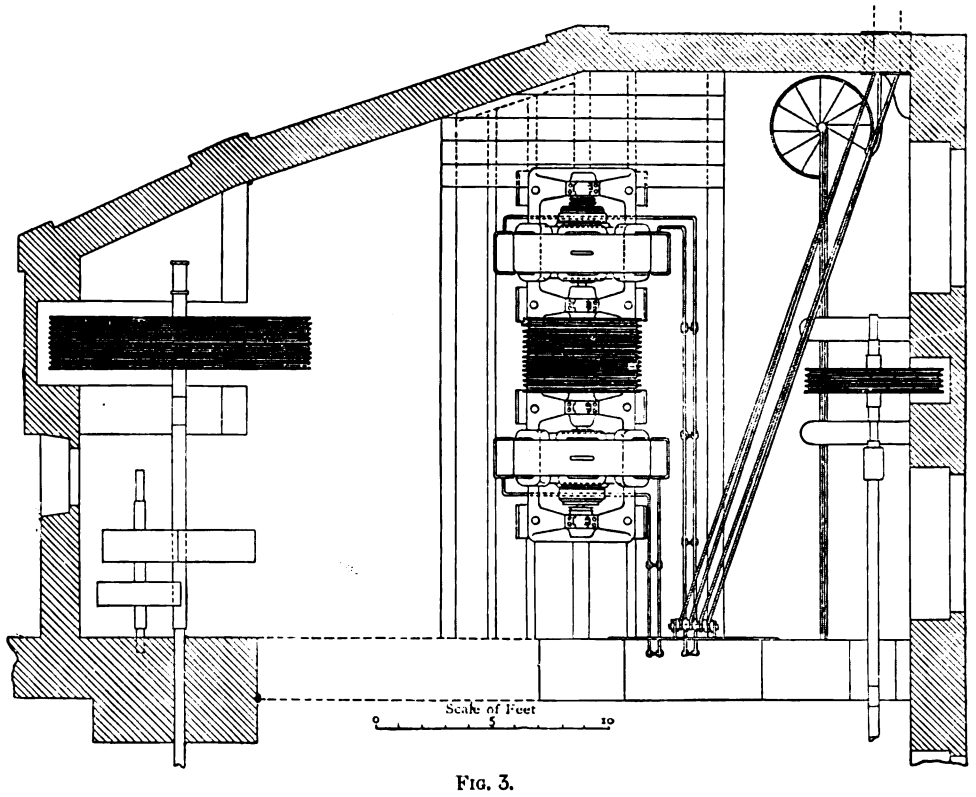

FIG. 3.

cut off the short circuit current before any harm is done to the machinery. The movable plate of the lightning protector is connected to the core of a solenoid, through which the short circuit current must flow. Immediately this current is started, the core is sucked in, and the movable plate falls away from the fixed plate, thus acting the part of an automatic switch.

Returning now to the Schaffhausen plant, the generating station contains two 300 H.P. dynamos, which are over-compounded, so as to produce a constant pressure of 600 volts at the motor station, the loss in the line being with full current 24 volts. These machines have series-wound drum armatures, running at 200 revolutions per minute. Their more important electrical data, as well as those referring to the motors, are given in the table on the next page.

variable resistance, which was withdrawn after the motor had gathered enough speed to make this safe. There is no inconvenience in using such a resistance when we are dealing with small currents; but when it is a question of several hundred amperes, and the absorption of as many horse-power, the resistance becomes a very cumbersome and unwieldy appliance. To get over this difficulty, Mr. Brown has devised a very ingenious method of coupling between the line and machines, the essential features of which are shown in Fig. 6. As I have already mentioned, there are four main cables, two positive and two negative. Three of these cables contain no switches which need be used for starting, although of course they contain the switches and fuses which may be required for testing purposes and as safety devices, but these, not being

Digitized by Google

essential to the explanation of the starting arrangements, I have not shown in the diagram. Call the two outer cables positive, and the two inner cables negative. The positive cables are looped at both terminuses, and the inner cables are also looped in this way, but a switch is inserted in the right-hand cable at the motor station.

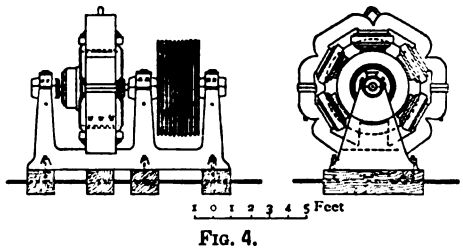

FIG. 4.

Now imagine all the machines at rest, and this switch to be open. To start the plant, the turbine-driven generator, G_1, is set in motion, and the speed run up till this machine excites itself by its

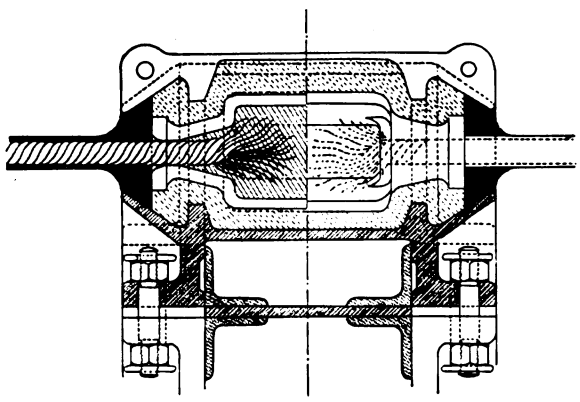

FIG. 5.

own shunt. If you follow the connections you will find that the shunts of the other three machines will at the same time also become excited. The motors have now made their fields, and if we start the second generator, G_2, slowly, a power current of gradually increasing strength will be sent through both motors, and the

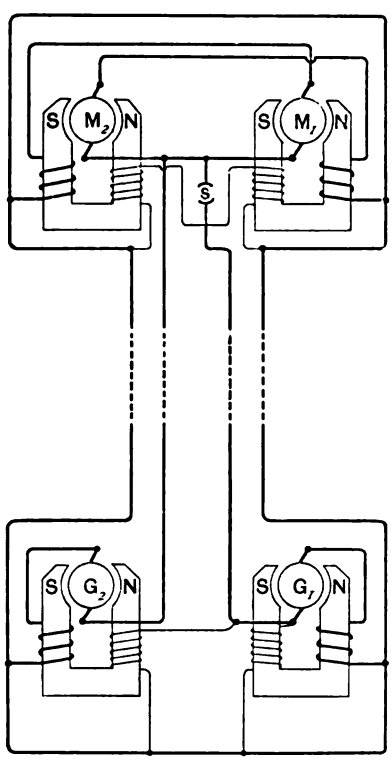

FIG. 6.

latter will gradually start. As they gather speed, their counter E.M.F., which is indicated by a voltmeter at the motor station, gradually rises; and if it has become equal to the E.M.F. indicated by a second voltmeter in connection with the current from the first generator, G_1, the attendant closes the switch, and the operation of starting is completed. It should be noted that on closing this switch there is no sudden rush of current, since the pressure on both sides of the switch is approximately equal.

Originally the motors were intended to be pure shunt machines, but it was soon found that, owing to the very small armature resistance and armature reaction, it was very difficult to get the load equally divided between them. Mr. Brown, to overcome this difficulty, hit upon the ingenious device of making the machines mutually control each other by putting on demagnetising main coils, and crossing the connections between armatures and fields, so that the machine, which might at any moment develop a tendency to take more than its fair share of current, would have its field strengthened by the deficiency of current passing through its main turns to the other armature, and would thus immediately raise its counter E.M.F., and check the excess of current, whilst the other machine which was not taking enough current, would have its field weakened, and would thus be forced to take more current. It is clear that by this cross-connection even a neglect on the part of the attendant to set the brushes properly cannot materially influence the even division of current and load between the two machines. At the same time the demagnetising influence of the main coils has the same effect as if the armature reaction was increased, and insures thus constancy of speed, as I have shown you experimentally last week. In the diagram, Fig. 6, the machines are represented as if they had only two poles each. This I have done to make the diagram as simple as possible, and for the same reason I have shown the shunt and main coils on separate magnet limbs, but you will have no difficulty in translating in your own mind this principle of circuit connections to multipolar machines.

It may interest you to have a few details of a commercial nature regarding this transmission plant. The manufacturers have guaranteed a commercial efficiency at ordinary full load of 78 per cent., also that the machines must be capable of transmitting an excess of 20 per cent. over their normal power for one hour and a-half without damage. The wear of one set of brushes to be not less than 2,000 hours, and the life of a commutator not less than 20,000 hours. The variation of speed of the motors between running idle and under full load not to exceed 3 per cent. The total cost of the electrical part of the plant, including cable towers and erection, was £6,800, or £13. 12s. per net horse-power delivered.

THE PROPAGATION OF ELECTRIC DISTURBANCES ALONG CONDUCTING WIRES.

In *La Lumière Électrique* of August 8th, Prof. Hertz offers some remarks on a contribution to that journal by M. J. Blondin, which appeared in its issue of July 18th. M. Blondin opened his article with the following remarks :—"According to Maxwell an electric disturbance should be propagated along an insulated conducting wire with the same speed as through the dielectric medium surrounding it. To show that this is so would, therefore, contstitute an invaluable verification of the truth of the theories of the English *savant*. The determination oi the speed of propagation of electric waves in metallic wires has been of late the subject of much work, the most important of which has been described in this journal (*La*

Digitized by Google

Lumière Électrique). Unfortunately, the contradictory results arrived at, so far from confirming the theory of Maxwell, seemed to show that it could not be applied without modification to propagation along conductors, and it is only quite recently that the question has been definitely settled in a sense favourable to Maxwell's ideas by the work of MM. Sarasin and de la Rive.* I therefore think it useful to take up the systematic study of the propagation of periodic electric disturbance along a conducting wire."

To this systematic study Prof. Hertz replies as follows :—"M. Blondin treats in an extremely just and kind manner certain errors which, it seems, have crept into my researches. I have scarcely anything to add to the very clear explanation of M. Blondin, and I am only desirous of taking this opportunity of myself stating in this journal that the conclusions which M. Blondin arrives at are in perfect accord with my present conviction, although they disagree with the results of the experiments which I published a few years ago. When I began these experiments, I was inclined to think that they ought to furnish two identical speeds, and I was astonished and disappointed to find that experiment gave unequal speeds. On this account I am fairly confident that I did not carry out my experiments with preconceived ideas, and in repeating them at the same place and under the same conditions I over and over again obtained the results published in my Papers. This does not preclude the idea that local conditions, either unknown or badly interpreted, had a disastrous influence, and falsified the results. To see if this were so, I endeavoured to repeat the reflection experiments in my present amphitheatre, which is a fine room, 17 metres long, 12 metres broad, and 5 metres high, without iron pillars to interfere with the experiments. I was, therefore, hopeful of obtaining excellent results and certain success. Unfortunately, the benches, which I was unable to remove, were ranged one above another in tiers in such a manner that I was obliged to give to the waves a somewhat inclined direction, unsymmetrical with regard to the horizon and the walls of the room. Under these conditions for waves several metres in length, the experiment succeeded very badly. The interference phenomena were much less pronounced than I had usually found them ; the nodes were so ill-defined that their true position remained doubtful to within more than a metre. Once again, therefore, I was obliged to give up the idea of personally experimentally verifying the facts.

"Nevertheless, these experiments enabled me to ascertain how great may be the influence of local conditions on long waves in a room of moderate dimensions and not completely empty. I even think that any such closed space complicates vibrations and produces effects analogous to acoustic vibrations in cubic tubes ; that is to say, tubes the dimensions of which are approximately all the same. If this is so the intensity of the disturbance and its distribution in space will depend in a large measure on the relation which exists between the period of the exciter and the period of the vibrations proper to the closed space, on the position of the exciter relative to the nodal surface of the simple vibrations, &c., &c.

"Perhaps we shall find in these considerations a possible explanation of the diverse results obtained ; in any case I do not publish them as a proven explanation. However, it does not seem to me that the beautiful experiments of MM. Sarasin and de la Rive were carried out under better conditions than were my own. If any physicist has at his disposal a large gallery, 8 metres high and 8 metres broad, and from 20 to 40 metres long, I think that even now it would not be lost labour to repeat these experiments on a large scale in order to remove the last uncertainty from science. I do not doubt that such an experiment would verify the results of the Geneva physicists. In a laboratory of ordinary dimensions, I think it would be very difficult to get a certainty greater than that already obtained."

CONTRIBUTIONS TO THE THEORY OF SECONDARY CELLS.†

BY F. STREINTZ.

This Paper considers the capacity and efficiency of elements with positive plates of various sizes. For the experiments E.P.S. plates, supplied by Messrs. Getz and Odendall, of Vienna, were sawn up so that the cut passed through the middle of the lead framework. The active material was thus not interfered with. Three elements were tested : in I., the positive plate contained 5×5 meshes of the lead network ; in II., 5×6 ; and in III., 6×6 ; the distances between the elements in each case were 1·5cm. In a larger vessel was placed an amalgamated zinc plate in dilute sulphuric acid ; by means of a glass syphon this could be put into communication with the contents of each of the three elements, for the purpose of determining the potential difference between the zinc and the plates of the accumulators.

The experiments were conducted as follows :—The element was first charged by a known current for several hours beyond the point at which the negative plate began to give off hydrogen. It was then discharged with the same resistance in the conductors until the current strength fell 10 per cent. below its stationary value. This discharge, during which the potential and current strength were taken every hour, served to determine the capacity. On the following day it was again charged at the same current, but this time the charging was stopped as soon as hydrogen began to be given off ; finally came a discharge under similar conditions, following usually immediately upon the charge. The observations taken during the second charge and discharge served to determine the efficiency.

The tests showed that the capacity, *i.e.*, the number of watt-hours which an element was capable of giving out before the current strength fell 10 per cent., increases as the current strength diminishes. The element II. showed the highest capacity of the three.

It was demonstrated that a reduction in the size of the positive plate conduces to an increase in the capacity, the efficiency at the same time not being lowered.

LONDON CHAMBER OF COMMERCE.

MEETING OF THE ELECTRICAL TRADE SECTION COMMITTEE.

A meeting of the Committee of the Electrical Trade Section of the London Chamber of Commerce was held, on Friday last, at Botolph House, Eastcheap, for the purpose of conferring with the Directors of the Crystal Palace Company as to the desirability of postponing the proposed Electrical Exhibition. Mr. R. E. Crompton occupied the chair, and amongst those present were Messrs. Moritz Immisch, R. S. Erskine, G. Binswanger, Shirley Price, E. J. Paterson, George Offor, W. J. Rivington, W. T. Goolden, Musgrave Heaphy, and R. Applegarth.

The CHAIRMAN opened the proceedings by reading a lengthy letter from Major Flood-Page, suggesting the advisability of postponing the Exhibition until July next, and the probability, in that event, of the Crystal Palace Company securing the support of a joint Committee of the Section and of the Council of the Institution of Electrical Engineers.

On the Directors being introduced, the CHAIRMAN laid Major Flood-Page's letter before them, and said that he understood they had come together in order to arrive, if possible, at some agreement as to the advisability, in the interests both of the Crystal Palace and of the Electrical Trade, of postponing or of going on with the proposed Exhibition.

Captain HENSHAW RUSSELL (Manager of the Crystal Palace) said that he had already received sufficient applications for space to occupy the entire area available. Over 50 firms (56 he thought was the exact number), many of them first class firms, such as Johnson and Phillips and Easton and Anderson, had applied. The object of the Crystal Palace Company was, of course, to make the Exhibition representative, but it must be remembered that the Company was under certain obligations to the firms who were prepared to exhibit in November. For his part, he thought July a very bad month indeed to open an Electrical Exhibition. For an electric lighting show the winter time was, in his opinion, the best ; they then had four or five hours every evening, instead of one, during which they could light up.

The CHAIRMAN said that the feeling of the trade was that they had been in a constant state of exhibiting since the first one at the Palace. He thought, however, that a thoroughly representative and exhaustive Exhibition, accompanied by trials of plant, would be of some good to the industry, but such an Exhibition could not be got together without considerable preparation.

One of the Directors suggested, as a compromise, that the date of opening should be postponed until the 1st of January.

Mr. G. T. RAIT, of the Crystal Palace Company, asked the Committee to remember that it was the Crystal Palace Company which would have to bear the financial risk of the Exhibition. The Directors were indebted to the Section for the interest it had taken in the matter, and they cordially invited the Section and the Institution of Electrical Engineers to support them. The Crystal Palace Company were, however, of opinion that the Exhibition should go on.

The CHAIRMAN failed to see where the financial risk of the Crystal Palace Company came in, and thought the exhibitors ran the most risk. If the Exhibition failed to attract *customers* the trade would regard it as a failure, but the Crystal Palace Company

Digitized by Google

had only to attract the shilling-paying public. He was afraid they looked at the matter from two different points of view.

After a few further remarks the Directors withdrew, and a discussion ensued, in the course of which Mr. OFFOR stated that if the Exhibition came off, the Company he was connected with was prepared to transmit 400 H.P. to the Palace, from a distance of 1½ miles, on the continuous-current transformer system.

The following resolution was finally proposed by Mr. GEORGE OFFOR, seconded by Mr. SHIRLEY PRICE, and carried :—

"That, in the opinion of the Electrical Trade Section of the London Chamber of Commerce, the offer of the Crystal Palace Company to postpone the opening of the Exhibition to January 1st, 1892, while affording a compromise in point of time, is not entirely satisfactory, but, in view of the fixed determination of the Directors to hold an Exhibition, this meeting advises firms in the electrical trade to support it as far as possible under the circumstances."

Mr. W. T. GOOLDEN then proposed, and Mr. MORITZ IMMISCH seconded, the addition of the following rider :—

"At the same time, this meeting strongly urges that the prospects of the success of the Exhibition would be greatly improved if the Directors could see their way to still further postpone the opening of the Exhibition until the autumn of 1892, which would appear to be a very favourable date for holding an Electrical Exhibition."

On being put to the meeting this was unanimously agreed to.

The Secretary was requested to intimate, in forwarding this resolution to the Secretary of the Crystal Palace Company, that, in accordance with the suggestion which they had made to the Directors in conversation—a suggestion which the Directors had welcomed—that they would be prepared to appoint a Committee to co-operate with the Crystal Palace authorities in their efforts to make the Exhibition a success, on being formally invited to do so.

The CHAIRMAN then read a list of the firms who had, in response to the Chamber's circular, agreed to visit the Frankfort Exhibition in the form of a party from September 5th to 15th. The Chairman and Mr. Binswanger agreed to co-operate with the Secretary in making the necessary arrangements for the party, such as hotel accommodation, &c.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 1, 1891.

Electrical Business.—News from Pittsburgh states that the Westinghouse Company is now pretty completely reorganised, and that the outlook there is brighter than it has been for many months. The Edison Company has recently been pushing its mining machinery, especially the reciprocating rock drill, but of the long predicted alternating current system there are no signs as yet. The Directors of the Company have not yet made up their minds what they want to do about prosecuting infringers of the lamp patents. Presumably the next few weeks will develop a definite policy of some sort or other. Of the larger electrical companies the Thomson-Houston is at present the most active and, a large number of installations are under way, though none of them of any great size. The bulk of electric lighting work in this country is done in towns and the smaller cities, especially through the West, so that although the aggregate is considerable, no individual job is of any formidable size. The Edison lamp decision is still a fruitful theme of conversation, and it is singular to notice how general seems to be the opinion that the decision was influenced by the great reputation of the inventor? Still, even the opponents of the Edison interests acknowledge that the moral effect of a strong decision sustaining an important patent is excellent, for so many patents have been broken down recently that inventors are far from being encouraged.

Rapid Transit in New York.—The Rapid Transit Commissioners have, as you have probably noticed through the daily papers, planned a subsidiary route up the east side of New York City. They have carefully abstained so far from giving any useful information as to the probable nature of the underground structure they propose erecting. The two still most important are the Reno and Greathead systems of tunneling. The former being a four-track tunnel that is looked upon with considerable favour by the commissioners; the latter being too familiar to you to need comment. Mr. Frank J. Sprague has shown himself very strongly in sympathy with the Greathead system, although whether he has any official connection with it is unknown. He is certainly abundantly able to push the electrical work through to success whatever form the enterprise may take. Meanwhile the cable road on Broadway is going down rapidly, in spite of the rumours that have from time to time gained currency that this plan was to be abandoned. The borings made by the Rapid Transit Committee along Broadway show that the task of tunneling in the lower part of the city will be comparatively easy, as rock is not encountered in quantity until the vicinity of Union Square is reached; above that point the engineering work will present few great difficulties, but a very large amount of rock cutting will have to be done.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all, Vol. I., 20; Vol. II., 18), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

TENDERS INVITED.—EXTENSION OF TIME.—The time for delivery of tenders for lighting the Southampton Royal Pier by electric light, and providing and fixing two electric cranes on the Town Quay, has been extended to September 8th. Further particulars will be found in our advertisement columns.

SALE BY TENDER.—Mr. Frederick Miller announces in our advertisement columns that, by direction of the Official Receiver, he will sell by tender the electric appliances belonging to Mr. J. Scott, at 13, Apple-tree-yard, York-street, St. James's, and Marylebone-mews, High-street, Marylebone. The stock may be viewed on Wednesday and Thursday next, and forms of tender may be obtained at the vendor's office, 2, Soho-street, Lincoln's-inn-fields, W.C.

MESSRS. W. T. GOOLDEN AND CO.—We are pleased to learn that at this, the slackest time of the year in the trade, this firm are very busy, and have in hand a large number of dynamos for lighting as well as complete plants for transmitting power.

PRIESTMAN'S OIL ENGINE FOR ELECTRIC LIGHTING.—About two years ago Priestman's Oil Engine was put upon the market, and the makers assure us that the progress made has been very satisfactory. A large number of orders have been received for engines varying in size from 1 to 25 actual H.P. for electric lighting, and Messrs. Priestman's works have been largely extended, with a view to giving prompt deliveries. It is claimed for this engine that it runs with exceptional steadiness and great regularity; can be easily fixed; is not dangerous, having no boiler to burst or keep in repair, requires no driver, and therefore works with great economy, can be kept in good working order by an unskilled man; and finally that, using only heavy mineral oil, no extra insurance is charged. Amongst orders recently executed for electric lighting may be mentioned a second order from Messrs. B. Verity and Sons, a third order for a 9 H.P. engine from Mr. F. M. Newton of Taunton, a second order for a 5 H.P. engine from Messrs. Anderson and Munro, and the New South Wales and Victorian Governments have recently adopted the Priestman engine for electric lighting purposes, the latter using a 25 H.P. engine. Mr. W. J. S. Barber-Starkey has recently given the following testimony :—"I have for the last nine months used one of Messrs. Priestman's engines for electric lighting, and it has given me every satisfaction. As I have it arranged the charging current is so steady that the needle of the ampere meter placed in the charging circuit shows hardly any perceptible fluctuation."

GAIETY THEATRE, DUBLIN.—An electric light installation has just been fitted up in this theatre by the Electrical Engineering Company of Ireland, under the supervision of their engineer, Mr. Porte, and of Mr. Harry South, of Garrick-street, London. Two Otto gas engines of 14 H.P. each drive two compound-wound dynamos, built by Messrs. Lawrence, Scott and Co., of Norwich, which supply current to 250 lamps. A feature of the installation was the rapidity with which it was fitted up, everything having been done within three weeks of the order being received.

ANNUAL DINNER.—The *employés* of Messrs. Swinburne and Co., of Teddington, held their first annual dinner on Friday last. A feature of the outing was the journey from Staines to Windsor in a steam launch. Notwithstanding occasional showers, a pleasant day was spent.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

July 7, 1891.

11,497. J. McLaren. Edinburgh. An hydro-electric lift.

11,519. E. A. Le Sueur. London. Improvements in diaphragms for electric cells.

11,526. F. G. W. J. Adams. London. Improvements in and connected with portable electric lamps, and in primary electric batteries and lenses for deflecting light to be used therewith.

11,538. G. Prokofiew. Chiswick. An electric traction magnetic conductor.

11,539. G. Prokofiew. Chiswick. An improved dynamo machine.

11,560. G. G. M. Hardingham. London. Improvements in and relating to galvanic batteries. (J. R. Hand and H. Connett, United States).

July 8, 1891.

11,620. E. E. Lever. London. Improvements in apparatus for preparing bleaching solution and bleaching powder by electrolysis.

11,625. J. H. Holmes. Liverpool. Improvements in the method of and apparatus for making electrical connections.

11,644. I. A. Timmis. London. Improvements in the lighting of trains by electricity.

11,645. R. B. Evered and T. Rudling. London. Improvements relating to combination gas and electric fittings, and to gas fittings.

July 9, 1891.

11,668. J. Parkes. Liverpool. Electric lighting of ships' compasses transparent cards.

11,712. H. C. Bull. London. Improvements in or connected with electric batteries.

July 10, 1891.

11,720. J. H. Tucker. Erdington. Improvements in electrical switches.

11,746. F. Van Houten. London. Improvements in telegraphic apparatus

11,756. W. Brock and W. H. R. Saunders. London. Improvements in electrical railway signalling.

11,762. G. H. Dörken. Barmen, Germany. A button commutator or cut-out.

11,767. J. E. Kingsbury. London. Improvements in telephone switchboards.

July 11, 1891.

11,801. R. D. Haines. London, Improvements in the manufacture of insulating conduits, or coverings for electric conductors. [Date applied for under Patents Act, 1883, Sec. 103, 12th December, 1890, being date of application in United States].

July 13, 1891.

11,836. A. Cance and Societe Anonyme d'Appareillages and d'Eclairages Electriques. (Lampes Electriques Cance). London. Improvements in electric arc lamps.

11,891. W. P. Thompson. Liverpool. Improvements in and relating to switch devices for effecting the connections in telephone systems. (J. Dietz, Germany).

July 14, 1891.

11,964. H. E. Newton. London. Improvements in accumulators for direct-acting engines. (C. P. Worthington, United States).

July 15, 1891.

11,978. A. R. Upward. London. A system and apparatus for the evolution and diffusion by electrical energy of disiufectants, antiseptics, and substances of a like nature.

12,004. R. Whitehead and A. Doxey. Sheffield. An improved microphone transmitter.

12,014. A. T. Collier, A. Marr, and W. F. Bottomley. Manchester. Improvements in telephonic transmitters.

12,018. E. Wilson. Charlton. Improvements in electrical gear for steering ships, and controlling the movement of holophotes, guns, and the like.

12,019. W. L. Wise. London. Improvements in the manufacture of carbons for electric arc lamps. (The Rheinische Fabrik for Elektrische Bogenlichtkohle W. Grüdelbach, Germany).

12,036. S. W. Maquay. London. Improvements in primary batteries.

12,040. A. A. Dykes and W. B. Hird. London. Improvements in voltmeters.

12,046. J. Sahulka. London. Improvements in or relating to electric motors.

July 16, 1891.

12,069. H. D. Fitzpatrick. Glasgow. An improved electrode plate for electric collectors. (K. F. Schöller and R. H. Jahr, Germany).

12,070. H. D. Fitzpatrick. Glasgow. An improved method of reciprocating the anchor of an electric apparatus. (K. F. Schöller and R. H. Jahr, Germany).

12,009. S. W. Maquay. London. Improvements in electric motors.

12,106. F. V. Maquaire. London. Improvements in and relating to electric lamps or lighting apparatus.

12,107. W. E. Dow. London. Improvements in drops or suspending mechanism for electric light and other like fittings.

12,117. E. Hartmann and W. Braun. London. Improvements in electric current meters.

July 17, 1891.

12,133. R. J. Bott. London. Improvements in the automatic contacts of incandescent lamp holders.

12,188. R. H. Barrett. London. Improvements in and in connection with incandescent electric lamps.

July 18, 1891.

12,244. J. S. Nettlefold. London. Improvements in portable electric lamps.

12,257. P. Scharf and R. Latzko. London. Improvements in the manufacture of electric incandescent or glow lamps.

July 20, 1891.

12,285. A. A. Goldston. Middlesbrough. A magneto advertising or displaying device.

12,286. C. S. F. Mellor. London. Economic electro-motor and motive power.

12,296. A. S. Elmore. London. Improvements in apparatus for the manufacture, by electrolysis, of tubes and other articles of circular section.

12,313. E. C. C. Jungnickel. London. Improvements in electric batteries

July 21, 1891.

12,322. A. J. Boult London. Improvements in or relating to electrica welding. (J. H. Bassler, United States).

12,384. M. Mackay. London. Improved compound for insulating electric wires in general.

July 22, 1891.

12,415. F. E. Stuart. Twickenham. Improvements in and relating to quick hitching harness and its operation by electric current.

12,416. A. Marr. Manchester. Improvements in telephonic transmitters.

12,455. J. Wetter. London. Improvements in electric locomotives. (H. Bonneau, France).

July 23, 1891.

12,484. A. R. Bennett. London. Improvements in telephonic switching apparatus.

12,491. C. L. Baker and Woodhouse and Rawson United (Limited). London. Improvements in the construction of rheostats or similar electrical instruments.

12,503. E. Owen. London. An improved electric ear-ring for curative and remedial purposes.

12,525. G. S. Grimston and A. H. Dykes. London. Electrical steering gear.

12,529. H. Edmunds. London. Improvements in means for distributing electric currents.

12,531. D. Bouchard. London. A new or improved apparatus for producing pictures upon a screen in stereoscopic relief by means of electricity.

12,535. A. P. Newton. London. Improvements in switches for electric installations. (A. Swan, United States).

12,540. H. Cuénod, E. Sautter, and G. Hochreutiner. London. Dynamo-electric machines. [Date applied for under Patents Act, 1883, Sec. 103, December 31, 1890, being date of application in Switzerland].

12,541. H. Cuénod, E. Sautter, and G. Hochreutiner. London. A system for the automatic regulation of the position of the brushes of dynamo-electric motors. [Date applied for under Patents Act 1883, Sec. 103, December 31, 1890, being date of application in Switzerland].

July 24, 1891.

12,592. H. H. Lake. London. Improvements relating to the manufacture or preparation of carbons for electric lamps or lighting apparatus. (Lacombe and Co., France).

12,602. H. Aron. London. Improvements in apparatus for measuring electric currents.

12,605. H. H. Lake. London. Improved means for securing terminals or binding screws to plates or electrodes for electric batteries. (Lacombe and Co., France).

12,611. J. W. Swan. London. Improvements in or connected with the electrolytic deposition of copper.

12,622. N. Wells. Newport. An improvement in electric clocks.

12,628. J. J. Hargreaves and R. W. Nuttall. Bradford. Improvements in couplings and terminal connections for electric cables.

12,634. A. D. Macdonald and J. Dodd. Liverpool. Improvements in apparatus for electrical sound and sight signalling on railways and other lines of rail.

COMPANIES' MEETINGS & REPORTS.

Cuba Submarine Telegraph Company (Limited).

The fortieth ordinary general meeting of the shareholders of this Company was held at the offices, 58, Old Broad-street, on Wednesday, under the presidency of Mr. Thomas Greenwood.

The CHAIRMAN, in opening the proceedings, said: The Secretary will read the notice convening the meeting.

The SECRETARY (Mr. James Scott) having read the notice,

The CHAIRMAN said: The Board has very little intelligence for you to-day beyond that already given in the report. As so many shareholders failed to attend these meetings, the Board has always been very anxious to give in the report every information to them that they are likely to want. I apprehend that you have made yourselves acquainted with the purport of that document, and that it need not be read before I move the adoption of the report and accounts. I may, however, draw your attention to a few points that may be of interest to you. The receipts of last half-year compared with those of the corresponding period of the previous year were not quite so large. That was not owing to any want of trade, but to the impediments caused for a few days by the breakdown of our cables. As, however, we have our cables now duplicated from end to end, it is highly improbable that such a circumstance will occur again, and, therefore, we may expect that the public service will be continued without interruption and with no loss to the Company. The repairs have been completed during the half-year, and the charge has been rather less than in the corresponding period of 1890; the result is that we have ra her a larger sum to carry to the credit of our reserve fund. The reserve fund, as you see, now amounts to £78,000. We have spent about £22,500 upon new cable, so that but for that outlay, which really is property invested for use, our reserve fund would now amount to rather over £100,000. I think that that is a very satisfactory state of affairs. The suit with the Spanish Government makes slow progress. Lawsuits even in England do not go very fast, and in Spain I think that the lawyers are, perhaps, rather more lethargic than they are here. The Government has lodged in the Court the papers in their hands which it was necessary for them to do before any further steps could be taken, and we have made our plaint. It was lodged within 10 days, the time allowed for such cases. The case is before the Court now, but when it will come on for hearing I cannot say. The delay has not been prejudicial to us. All that we want, indeed, is that there may be perpetual delay. We want a decision that the Government have not the right to grant this concession, and until that is decided against us we are going on with our business, and our opponents can do nothing. So far, delay is beneficial to us, and we have no cause to complain on that ground. I am not aware that there is anything more in the report, or in the circumstances of the Company as a whole, that I need mention to you, but if there is anything further upon which you may be desirous of receiving information, we shall be very pleased to furnish it. The formal resolution which I have to propose is:—

"*That the report and accounts for the half-year ended June 30th last, now submitted, be received and adopted.*"

Mr. ALEXANDER F. LOW: I beg to second that.

Mr. COCHRAN: I do not know whether you could explain the great increase that has occurred in the item of depreciation on stores and cable in stock. I find, on looking back to the previous three half-years, that you have charged for that item £323, £313, and £219, whereas this half-year it has suddenly sprung up to £734, which is a very considerable advance. I did not quite catch what the Chairman said as to the £100,000, and about adding £22,000 to the reserve fund. I suppose those are the accumulated payments for the new cable.

The CHAIRMAN: No, you did not understand me. We have now a reserve fund of £78,000, after having spent more than £22,000 on the new cable. If that money had not been laid out upon the new cable our reserve fund would be £100,000.

Mr. COCHRAN: That is practically what I understood. It strikes me as rather a severe tax on our revenue that something like £8,000 should be written off in one half-year for really capital charges. We have paid half of the annual payment on account of the Cienfuegos-Santiago cable, £1,875, cable repairs, £3,698, and we carry to the reserve fund £2,656, making altogether £8,229 for the half-year, while the distribution to the shareholders is only £9,400. I have always felt that it is a wise thing to maintain the Company in a sound financial position, but at the same time I think that is rather a severe docking of our profits, unless it makes the future more secure, but I do not know that I am prepared to do more than simply draw attention to it. It seems to be rather a heavy sum to deduct from the gross profits.

Mr. W. GRIFFITH: I rather agree with the last speaker that the reserve fund is a very fine figure. I am in favour of safety and of everything that is necessary to secure the future welfare of the Company; but as we are fortunately paying a rent for one of our cables we do not need a reserve fund so strongly as other companies do. Other companies buy their cables and are unable to ensure themselves against any risk to them, and it is a point with them to have their reserve fund standing at a large figure, even though the interest earned by them is small. We have the additional security of, however, renting our cable, and the insurance of it is included in the rent. That is a question of policy which requires consideration. I would, like my brother shareholder, merely suggest that the reserve fund be kept down, and that, if possible, the dividend should be increased. That may be a selfish policy to some extent, but I think it may also be a safe policy. I must apologise for being a little late, and the question which I am going to ask may already have been answered. Have we anything to fear from the new line from Halifax to our neighbourhood? I suppose not, but you are able to tell us more surely about the future than we can guess it. Reading over the report, I was sorry to see that our old friend, Mr. Horatio Perry, had died. He was a gentleman who had served us extremely well in that very warm climate, which I found was too warm to be pleasant, although I have travelled over the south of Europe. I am sure that we ought to be very thankful to him for what he did for us.

The CHAIRMAN: Replying to the remarks of the two previous speakers, the stock of our material is always valued by our engineer, and we get his certificate at the end of every year. We have had it this year. The whole of the stock has been overhauled, and a revaluation has been made. This has caused, perhaps, some little increase in the charge for depreciation of the stock. Still, the stock is there, whether we value it at a larger or a smaller amount, and it stands in our books now at, perhaps, a lower value than it is; but it is better to err on the safe side and write off so as to keep down our assets to their true value. The figures quoted are, no doubt, quite accurate. We have charged our revenue with a large sum in the half-year, but that is mainly because the repairs have been done in the half-year. All repairs must be borne by the revenue in the half-year. There is nothing outstanding. The rent of the one line which we have taken from our manufacturers has hitherto been charged against revenue. I do not think there is any necessity for altering that. It had to be paid for 12 years, and as we have paid it for 10 years the line will be ours in two years more without paying any further rent. After that time we shall have to pay for the repair of it. During the period of the rent the cost of repairs have been paid, not by us, but by the contractors. I do not think it is wise to increase the dividend under present circumstances. We have before us, as you know, the possibility of opposition, which may materially reduce our receipts. I hope the dividend will never go below 8 per cent., but while we maintain it at that rate I think it is a highly satisfactory return, especially if we can sustain it and yet put something more to reserve fund than we should do but for the fact of the threatened opposition. I hope that if the opposition goes off we shall be able to increase the dividend, but if we can sustain it at 8 per cent I think the shareholders generally may feel that it is a satisfactory result. As to the threatened opposition *vid* Halifax, the line has been made from Halifax to Bermuda, but we have heard nothing of its being extended beyond Bermuda. He then put the motion to the vote in the usual way, and declared it carried unanimously. Continuing, he said: The next resolution is:—

"*That the following dividends for the half-year be now declared upon the shares of the Company, viz., at the rate of 10 per cent. per annum, subject to income-tax, on the preference shares, and 8 per cent. per annum, free of income-tax, on the ordinary shares, payable on and after to-morrow.*"

Mr. CHARLES W. PARISH: I beg to second that.

The CHAIRMAN put the motion in the usual way, and it was carried unanimously, adding: It falls now to someone else to propose the next resolution.

Mr. LOW: I have much pleasure in proposing:—

"*That Mr. Thomas Greenwood be re-elected a Director of the Company.*"

Mr. JAMES GODDARD: May I have the pleasure of seconding that? I think our business has been carried on in the most prudent manner, and I quite agree with the Board in thinking that, while anything threatens us, it will be best to go on as we have done, making the reserve fund as large as we can, and writing off everything that we can.

The resolution was carried unanimously.

The CHAIRMAN: I thank you for re-electing me to my seat on the Board. I shall be pleased to do all that I can in the interests of the Company, and therefore in my own interests as one of the members of it. The next resolution must also come from the other side of the table.

Mr. HOOPER: I am sure that our accounts are presented to us in the way we should desire in every respect, and therefore I propose:—

"*That Mr. John Gane be re-elected auditor of the Company for the current year at a salary of 20 guineas.*"

Mr. BAYLES: I second the motion.

Mr. GRIFFITH: Is there any plan by which we should be able to have our accounts audited if Mr. Gane should unfortunately be taken to a better world? We were in that difficulty before, and I then suggested the advisability of a second auditor. I still retain that view.

The CHAIRMAN: We have had that question discussed at several meetings. The Board made a proposal to the effect that in the event of the death of the auditor occurring in the half-year the Board might appoint an auditor for that particular half-year; but the meeting did not approve this suggestion, and the Board did not wish to press it. As Mr. Gane is a young man and in good health I do not anticipate any difficulty occurring on this score. He

Digitized by Google

then put the resolution to the meeting, and it was unanimously adopted, adding: I thank you for your attendance; the business is done.

Mr. HOOPER: May I propose a special vote of thanks to Mr. Keith for the work which he has done in the past half-year? I have seen Mr. Keith, and I feel that as long as you have him as your engineer you may be sure that anything that can be done for you at Cuba will be done. At the same time the shareholders must remember that they are dependent on two deep sea cables, one laid in 1875 and the other in 1881, the latter being manufactured as early as 1874. That was put down at the risk of the contractors, who agreed to maintain it for 12 years. That cable has fortunately stood well, and the interruption to it has been made good, but it was due to Mr. Keith that it was made good, and he not only repaired the 1881 cable but also the cable laid in 1875, and the cable between Cienfuegos and Batabano. I have been out there, and it will be satisfactory to you to know, with regard to those photographs on the wall, that the works are in first-rate order. I was surprised to see what work could be done at that workshop. You see cable there that has been recovered from the water, and it is utilised over again. The engines, boilers, and apparatus which Mr. Keith has out there are in very good order, and are well worth the money shown in the balance-sheet, and the staff out there seemed to use their best endeavours to repair the interruption to the two cables which occurred last February. Speaking as a shareholder, I think that our thanks are due to the staff in Cuba for their work in the past six months. I only say what I feel myself, and I propose a vote of thanks to Mr. Keith and the staff in Cuba.

The CHAIRMAN: I am pleased that Mr. Hooper has spontaneously risen to speak in favour of Mr. Keith and his work. No one is better able than Mr. Hooper to speak on this subject. He was out there during the laying of the new cable and the repair of the old one. Mr. Keith has done his work well and at a moderate expense, and his whole time and attention are given to the work in the Company. He has also given his skill, which is very great. He is fully acquainted with the whole of our business there, and he has not only a knowledge of the business, but also of the language, which is a great desideratum. I should like to second the motion of Mr. Hooper, both on behalf of myself and the other members of the Board. The motion is that a vote of thanks be accorded to Mr. Keith and his staff for the work which they have done for us in the past half-year, which has been satisfactory to the shareholders and the Directors.

The resolution was carried unanimously.

Mr. COCHRAN: We do not usually separate without formally expressing the appreciation of those on this side of the table at the management of our affairs by the Directors. I am sure that while we all agree that a very large amount of our success must rest with the officials on the other side—and we all heartily concur in the observations made by Mr. Hooper—we also remember that some portion of our success must depend on the way in which the business is managed here. I, therefore, rise to propose a hearty vote of thanks to the Chairman and the Directors.

Mr. GRIFFITH: I have very much pleasure in seconding that. The proposal is certainly a reasonable one, and Mr. Hooper's proposal was most reasonable, and would commend itself to all right-minded persons, more especially as we have such valuable and incontrovertible testimony as to the value rendered to us by Mr. Keith. While, however, we properly render our thanks to those abroad, it is only right that we should acknowledge the services of the gentlemen on this side. I, therefore, have great pleasure in seconding the resolution.

The motion was carried unanimously.

The CHAIRMAN: It is very kind of you to think of us in this very agreeable manner. The Board very much appreciate your goodwill. I can assure you that we are doing our very best to promote the welfare of the Company. There are little difficulties that crop up which the Board have to deal with, and which have a large bearing on the question of the success of the Company. Hitherto we have succeeded in our dealing with these little difficulties, and I hope that we shall continue to do so.

The proceedings then terminated.

Montevidean and Brazilian Telegraph Company (Limited).

A general meeting of the members of the above-named Company was held at the office, Langthorn House, Copthall avenue, E.C, on Tuesday, August 11th, for the purpose of an account being submitted showing the manner in which the winding-up had been conducted. Colonel H. G. W. Macaulay presided.

The Liquidator's report presented to the meeting showed "The number of shares in the Western and Brazilian Telegraph Company (Limited), issued as the consideration for the purchase of the undertaking of the Montevidean Company, was 5,300, as stated in the Directors' circular of November 11, 1890. These shares were distributed as follows, in accordance with the special resolutions confirmed on December 10, 1890:—

To shareholders in the Montevidean Company	4,343
To debenture-holders in the Montevidean Company	650
To the liquidator, in satisfaction of his remuneration	10
To the Directors and secretary, as compensation for the loss of their offices	145
	5,148
Unappropriated balance, to be sold and proceeds applied towards the expenses of the liquidation	152
	5,300"

The financial position was stated as follows:—"As shown in the cash account, the unappropriated shares have been sold at £10. 17s. 6d. per share, the proceeds amounting to £1,653. The expenses of the liquidation, amounting to £164. 16s. 5d., have to be paid out of the proceeds of the above-mentioned shares, together with an amount of £380 for the redemption of debentures not previously charged to the Company's revenue account. As shown in the cash account the balance will allow of the payment of a first and final dividend of 2s. 5d. per share to the holders of all shares, whether preferred or deferred, in the Montevidean Company, amounting in all to £1,050. 12s. 11d., and leave the sum of £26. 9s. 5d. still unappropriated."

The CHAIRMAN stated that since the circular of Mr. George Fraser the liquidator, had been issued, the Stock Exchange had granted a quotation for the above shares. A large number of shareholders had sent in their proxies approving of the scheme. He paid a tribute of praise to Mr. George Fraser for the manner in which the liquidation had been carried out, and concluded by moving—

"That the liquidator's report and cash account, now submitted to the meeting, be approved and adopted."

The motion was seconded and carried.

A vote of thanks was accorded to the liquidator (Mr. George Fraser) for the manner in which he had carried out the liquidation of the Company; and a vote of thanks to the Chairman for presiding terminated the meeting.

United River Plate Telephone Company (Limited).

The fifth annual ordinary general meeting of this Company was held at Winchester House, 50, Old Broad-street, London, E.C., on Friday, August 7, 1891, for the purpose of receiving and adopting the report of the Directors and the accounts for the year ending March 31, 1891; and for transacting the ordinary business of the Company; Mr. J. Irving Courtenay, the Chairman of the Company, presided.

Mr. ROBERT HERRING (the Secretary) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said: Gentlemen, I rise to move the adoption of the Directors' report and statement of accounts. When I last had the pleasure of addressing you, now 12 months ago, I certainly did look for an improvement in River Plate affairs, but very shortly after the last meeting a revolution broke out in the Argentine Republic, and from that day to this it cannot be said that there has been any improvement financially; on the contrary, the gold premium has fluctuated violently, and the recent unfortunate failure of the English Bank of the River Plate has caused, if possible, an increased want of confidence on this side. The failure of that bank had no effect upon this Company directly, as it was not one of our bankers. By the direction of the Board an account which we had with its Rosario branch was transferred nearly a year ago to the London and River Plate Bank. I am aware that it is the opinion of many that matters have reached their worst, and there are undoubtedly some hopeful features in the situation, but the position changes so rapidly that I think it the wisest course not to attempt to give any strong opinion as to the probable course of events in the near future in the Argentine Republic. Regarding the results of the past year's working in our own Company, they have been entirely governed by one factor, namely, the gold premium, to which I will call your attention later on. The gross income for the past financial year was £106,259. 19s. 8d., as compared with £108,612. 2s. 7d. in the previous year. The difference arises solely from the diminution of our sales business, which, in consideration of the long credits customary in the River Plate, we have not thought it prudent to push. I desire to call your particular attention to the strength of the Company's business, notwithstanding the continued crisis, as shown by the figures I have just given. There has actually been more money received from subscribers and messages this year than was received last year, though there has been a considerable falling off in the total number of subscribers. We have had no less than 1,099 new subscribers come on our books during the past year, and I believe we shall find our experience to be the same as has been found in other enterprises, that the subscribers who come on during a period of financial tightness are more permanent subscribers and are better payers than those who come on during a period of inflated commercial prosperity. You must understand that there is no diminution in the demand expressed for telephonic communication, but our representatives are very wisely prompt in taking out telephones from bad payers. Our working expenses in the Plate were £56,941. 1s. 9d., against £63,497. 15s. 5d. for the previous year. This reduction of £6,556. 13s. 8d., being over 10 per cent., has been the result of economies made where practicable, notwithstanding the increased cost, to a considerable extent, of materials, general expenses, and taxes. The Directors have endeavoured to effect all economies possible in the management and expenses of the Company, and in this they have been effectively aided by our managers in the River Plate. Further economies, to some extent, are anticipated, but unless a reduction in the gold premium occurs a greater degree of expenditure must be expected; this would necessitate such a rise in our rates as would at least meet the increased expenditure. The capital outlay for the year has been £3,096. 10s. 10d., against £12,772. 8s. for the previous year, and though this figure is low, still a considerable amount of important work has been done which has been charged to revenue, such as a complete installation of lightning arrestors, which will prevent serious damage to our whole plant, including the multiple switch-board at the central offices, not only from lightning, but from contact with electric light wires. We have also pulled down old lines of the two old Companies, and have built several miles of new trunk lines, thereby reducing taxes on posts and expenses of working and maintenance. Our Buenos Ayres manager reports that our plant to-day is in a most excellent condition in every respect, and that its working is perfect; and from our other important centre, Rosario, the manager writes—"It is a great pleasure to me to be able to inform the

Digitized by Google

Board that the service, I am sure, cannot be beaten in any part of the world; complaints there are none." We had the advantage of a personal inspection by one of our Directors, Mr. Cooper, during last spring, who, on returning to this country, gave a most satisfactory report both as to the efficiency of the service and the general management of the business. The Directors, mindful of the necessity for diminishing expenditure in all directions, have, as stated in the report, reduced the London fixed expenses since the end of the financial year by one-third, so that these expenses now stand at about one-half of what they were for the previous year, *i.e.*, the year ended March 31, 1890. I have now, I think, touched upon most of the points in the Directors' report and the figures in the balance-sheet, and I can but express my great regret that we are unable, for the first time in the history of the Company, to declare a dividend. This is entirely owing to the loss on exchange, amounting to £36,049. 0s. 8d., or nearly 12½ per cent. on the Company's paid-up share capital, a loss, of course, wholly beyond our control. In spite of the extremely adverse circumstances we have had to contend with in the River Plate, and of which you are fully cognisant, the business of the Company has held its own remarkably well and shows an undoubted vitality; so that it may reasonably be expected that with only a slight revival of commercial affairs in Buenos Ayres and a fall in the gold premium, the Company would soon again be in a dividend paying condition. I may properly mention here that the latest telegraphic advices from Buenos Ayres, dated the 4th inst., state that our receipts for July are better than for the same month of last year, which cannot be regarded as other than satisfactory. Several changes have taken place during the past year in the administration of the Company. We have met a severe loss in the death of our colleague, Mr. John Coghlan, a gentleman widely and most favourably known in connection with River Plate affairs for very many years. Lord Thurlow, who was with us from the beginning, as our Chairman, felt obliged owing to the pressure of his other engagements, to tender his resignation as a Director, which the Board very regretfully accepted. Our late Secretary, Mr. Unwin, who has also been with us from the outset, resigned his post at the end of the year to enter into partnership with an old-established South American firm. The Board, desiring to retain the benefit of his valued services and long business experience in South American business, elected him to the vacancy caused by the death of Mr. Coghlan. It also appointed to the vacant secretaryship, Mr. Robert Herring, who has always been the Company's accountant, and who now unites the duties of both positions. Feeling the necessity of a more general supervision of the Company's affairs under this re-arrangement of the home management than could well be given by an ordinary Director, the Board have thought it wise to ask Mr. Frank W. Jones, one of its members, to take the position of Managing Director, which I am pleased to state was accepted by him. Mr. Jones, who is here to-day, and who is one of our largest share and debenture holders, was, as you will remember, Chairman and Managing Director of one of the enterprises in the River Plate upon which this Company was founded. I shall conclude my remarks—and shall be happy to give any further information that I can—by moving the resolution:—

"*That the report and accounts submitted to the meeting be, and they are hereby, received and adopted by the Company.*"

Mr. GEORGE COOPER: I beg to second it.

Dr. ELLIS: The speech of the Chairman has covered so much ground, and has covered it so very satisfactorily, that it leaves very few words for me to say, further than to ask one or two questions more or less for my own personal information than for anything else, and first of all I should like to inquire when the exchange—or rather the premium—on gold fluctuates from 200 to 300 per cent., how it is that the very large sum of £36,000, mentioned in your speech, is lost to bring home £38,000? I cannot understand how this is. That is one question I should like answered, and this is another: Whether it is necessary, when the exchange is so very adverse, to turn all our paper money which we receive into gold at once? I want to know whether it would not be better to keep a certain portion of it, at all events, out in the Bank at the River Plate and in Buenos Ayres against better times. Of course these are technical matters which I have no doubt can be satisfactorily answered; still, I should like to know. Then there is one other subject mentioned in your speech, that of extensions, and it is stated that a further £3,000 has been spent upon extensions. That has gone to capital expenditure, I suppose. I should like a little explanation upon that point. There is one other matter, too, to which I would like to refer, which is that all the figures and details in the accounts are given in pounds sterling. I know that it would be difficult, if not impossible, to mix pounds and dollars, but at the same time it is a little misleading. It seems that we have gone into a further £3,000 expenditure in the River Plate, and I want to know whether that really means £3,000, or whether, under present conditions of exchange, it does not mean about £15,000 or £20,000 in River Plate money.

The CHAIRMAN: I am sorry to say that I cannot quite see your point.

Dr. ELLIS: I want to know whether the £3,000 expended means £3,000 sterling; I mean the additional working outlay in the River Plate, because if it is not in sterling it becomes a very serious matter, and means a very large sum of money out there in paper, and shows the extreme necessity for avoiding any increase of capital expenditure at the present time, because 1,000 new subscribers would hardly pay for the expenditure of £3,000 sterling.

The CHAIRMAN: It is in sterling.

Dr. ELLIS: Well, with these few questions, to which I shall be glad to have answers, I need say nothing more except that I never heard a more satisfactory speech in many respects, and in regard to the explanations given to the shareholders, than has been given by yourself, sir, to-day. It has been a most exhaustive statement and as satisfactory a speech as any one that I have listened to that has not had for its termination the declaration of a dividend.

The CHAIRMAN: If there are no other questions to be asked I will rise to answer those of the hon. proprietor, Dr. Ellis, and he must first of all permit me to say how much I thank him for the kind expressions he has used with regard to the explanations given in my speech. The whole subject is a question—as I stated in my speech—of exchange, and we, as a Company doing business in that country, have auditors who have to pass these accounts, and, in order that they may be duly checked and audited, the money must be converted into sterling. We should be very glad indeed to avoid this if we could, but there is no help for it. We cannot present our accounts in paper dollars, and we are compelled to convert. The same question has occurred to us as has occurred to Dr. Ellis, whether, instead of converting our money into pounds sterling, we should leave the money there, as suggested, at some of the banks, and not convert it. Well, the first objection to that is that we want the money here to pay our debenture interest, and we have to bring the money over to pay the debenture-holders in sterling, and therefore we must convert; and then, again, you will observe that we should run a very serious risk if we did not convert our money, but left it there in the banks. That amounts to speculation upon the gold premium, because if it rose we should stand to lose, and if it fell to gain. Now, if we had not converted and brought over this money, which we have done, and if we had let it wait there in hopes of better times, and it had become necessary to bring over a large amount at the present time, we should have incurred a considerable and serious further loss. It is a policy pursued by other companies in the River Plate, and, after careful consideration, it is believed to be the wise one to convert the money at the rate of the day from time to time when necessary to bring it over, and not to speculate upon the probabilities of the rise or the fall which may take place in the gold premium, and which might lead to a very serious loss. Therefore we have adopted this policy, and we think that it is a very sound policy, and, as I said, we have the satisfaction of knowing that this policy is adopted by other Boards of Directors having heavy business interests with the River Plate. We have carefully considered the matter, as they have, and we have all arrived at the conclusion that it is the right policy to adopt. Now, with regard to the other point to which the honourable shareholder addressed his observations, viz., the question of the expenditure of £3,000 in the River Plate. You must remember that a large proportion of that was for materials. These materials are telephones and other things that are bought here (in London) and paid for in gold. Wages and other things over there are paid for in paper; therefore it does not represent the very large sum which you think, because a large portion, at any rate, as far as the bulk of the materials are concerned, have been bought here and paid for in sterling here.

Colonel ARMSTRONG: May I ask how much money has to be sent here from the River Plate?

The CHAIRMAN: We have had sent over here sufficient to pay the debenture interest and for the expenses of carrying on the Company.

Colonel ARMSTRONG: I suppose that amounts to about £9,000?

The CHAIRMAN: You will see it here in the figures.

Colonel ARMSTRONG: We seem to convert according to the accounts at a cost of £36,000 to send the money here.

The CHAIRMAN: We have no choice—we have to convert.

Colonel ARMSTRONG: The wages and other payments, I suppose, are made in paper there, and this is the cost for the conversion of the money sent home?

The CHAIRMAN: You may put it, if you like, as the cost of conversion there.

A SHAREHOLDER said that he did not understand the way in which the conversion was carried out, and he wanted to know whether the accounts showed that the whole of the money—every farthing of revenue that had been earned in the River Plate—had been sent over here.

The CHAIRMAN: All the surplus has been sent home.

The SHAREHOLDER: The surplus is what I mean.

The CHAIRMAN: Yes.

Dr. ELLIS: I do not quite understand yet how it is that the large sum of £36,000 is charged to send home £38,000.

Mr. J. OWEN UNWIN, a member of the Board (at the request of the Chairman), replied to the question, and said that he must admit that this question of exchange was a most puzzling thing for anybody to understand, but the Directors could assure the shareholders that there was no doubt that the accounts, as presented, were perfectly straightforward, but he would endeavour in one word to make the matter clear. They were dealing in a country with the depreciated paper currency, but the capital of this Company was raised in sterling, and their debenture interest was paid in sterling, and their dividends, when they came, were paid in sterling. They transmitted their capital, which was subscribed, out to the River Plate, and they had to deal with it in the currency of the country. Perhaps most of the shareholders were aware that when they took their capital out to the River Plate the exchange there, or rather the premium on gold, was very much lower than it was at the present time. In fact, when the Company was started, the premium on gold was something like, he believed, 30 per cent.

The CHAIRMAN: Yes.

Mr. UNWIN said that when they came to make up their accounts they had to convert the paper into sterling at the exchange of the day—the rate then ruling—and they must do this in order to avoid speculating. When their money was taken out it was, of course, what was then known as the "par of exchange," but that had long since wandered away, for the condition of things was entirely altered, and £106,000 in paper money was only really worth something like £40,000 or £45,000 in sterling. It did not matter what they dealt in—be it as a manufacturing company, be it as a railway company, be it as a gas company, be it as a telephone company, or be it as a merchant—if they were trading in a country with a depreciated currency, and their head-quarters were over here in England, they must convert their paper money into sterling at the exchange of the day. If they liked to leave their paper money over there—for instance, if this

Digitized by Google

Board of Directors liked to leave any surplus in the River Plate—they would have to borrow money against it on this side, and by leaving their paper money over there they would be "simply and solely speculating upon the rise or fall of the exchange." If it went up they would be losing money, and if it went down they would get more—it was simply a matter of speculation.

Dr. ELLIS: Excuse me interrupting you, but I do not think that you see the point. What I want to know is, how we could have lost £36,000 to bring home £38,000 at the present rate of the gold premium.

The CHAIRMAN: It is on the working for the year.

Dr. ELLIS: I thought it was on £38,000.

The CHAIRMAN: It is on the total transactions of the Company.

Mr. FRANK W. JONES: It is not upon £9,000 sent home.

Colonel ARMSTRONG asked further questions in regard to the same matter.

The CHAIRMAN stated that, as had already been explained, the matter was quite correct, and the accounts were duly audited.

Mr. FRANK W. JONES said he wished it to be clearly understood that the loss in consequence of the premium, as shown by the accounts, was not upon £9,000 nor upon £38,000, but was upon the entire working of the Company, and which had to be converted into sterling at the current rate of exchange of the day upon which the money was transmitted.

The CHAIRMAN: I will now put the resolution. It has already been read to the meeting. Those in favour of the same will signify it in the usual way, by holding up their hands. Against it. That is carried unanimously. The next business is the re-election of Directors.

Mr. FRANK W. JONES: I beg to propose that Mr. J. Irving Courtenay be, and he is hereby, re-elected a Director of the Company.

Dr. RAE: I beg to second it.

The resolution was unanimously carried.

Mr. FREDERICK GREEN: I beg to propose that Mr. J. Owen Unwin be, and he is hereby, re-elected a Director of the Company.

Mr. BILLETER: I beg to second the motion.

The resolution was carried.

The CHAIRMAN: The next business is the re-appointment of auditors, Messrs. Cooper Brothers and Co. It is a shareholders' question, and I will ask a shareholder to propose it.

Mr. RODGERS: I beg to propose that Messrs. Cooper Brothers and Co. be, and they are hereby, re-elected auditors of the Company for the current year.

Mr. EDWARD PINCHES: I have much pleasure in seconding the motion; it would be impossible to have more efficient auditors.

The motion was carried.

The CHAIRMAN: That concludes the business of the meeting.

Dr. RAE: I beg to propose a vote of thanks to be passed to the Chairman for the way in which he has conducted the affairs of the meeting to-day, and I agree with the gentleman who spoke earlier (Dr. Ellis) that I never heard a more clear and pleasant statement from a Chairman over a bad business than that which he has made to us to-day. He has put everything clearly before us in a wonderful manner. I did not myself quite understand the £36,000 cost of bringing money over—loss on exchange—but I begin to see how it is now. I have much pleasure in proposing the vote of thanks.

Dr. ELLIS seconded the motion, which was carried amid applause.

The CHAIRMAN, in reply, said: Dr. Rae and gentlemen,—I sincerely thank you for the very kind vote of confidence in myself, which I take also to be a vote of confidence in my colleagues. You will quite understand we have had a very anxious time during the past year—it has been a very anxious time for anyone connected with River Plate affairs—and all I can say is that I trust that the next time we meet you we shall have some of the dark clouds dispelled. I thank you for your attendance here to day, and for your vote of thanks.

The proceedings then terminated.

City and South London Railway Company.

The fourteenth ordinary general meeting of this Company was held at Winchester House, Old Broad-street, on Tuesday, under the presidency of Mr. Charles Grey Mott.

The SECRETARY (Mr. W. F. Knight) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: It now becomes my duty to propose:—

"*That the report and statement of accounts for the half-year ended June* 30, 1891, *now submitted to the meeting be approved and adopted.*"

There is one matter connected with this report which I am sure you will have read with satisfaction, and that is that we have been enabled to carry over the line 2½ millions of passengers during the half-year without any accident whatever. I regret that a few days ago, for the first time in the history of the Company, a fatal accident occurred connected with the line, but as the passenger in that case acted in violation of the bye-laws of the Company, and in direct defiance of the officers of the Company who were carrying out those bye-laws, no blame could attach to the Company itself at all. At the same time you may be sure that we exceedingly regret such an accident, and that we sympathise very much with the relatives of the passenger. The past half-year has, as you can well imagine, been a very anxious one for the Board. In the first working of a new system, such as this, three points are naturally presented to the Directors: first, will the system of electric locomotion which we have adopted work at all? secondly, will it work satisfactorily? and, thirdly, will it work in such a way as to give a remunerative return to the shareholders for the money invested? On the first two heads we can report with confidence in the affirmative. We have worked the railway, and we have worked it satisfactorily. As regards the last head, I am sorry to say that at the present moment we cannot answer it with the same satisfaction as we can the two first. We have yet to show that this system is not only efficient, but also that it is one that will be a thorough financial success. As you have seen from the accounts, the past half-year has given us a profit which has enabled us to pay our debenture interest in full, leaving a very slight margin beyond. As we have no other preference charge at the present moment beyond our debenture interest, and beyond the very small sum that we may have to pay for the preference shares that may be issued—which is not a large amount, as you know, but very small indeed—any further profits on this line will go into the hands of the ordinary shareholders. I hope that our future profits will go on steadily increasing, and that it will not be very long before I may have the pleasure of standing here and feeling that we have earned a substantial dividend. But that rests with the future, and I do not like to prophesy—you know that I have always refused to do so, and wisely, I think. I prefer to deal with accomplished facts. Now, you may like to have a short *résumé* of our present position, financially. Our receipts from passengers during the past half-year—and they are the only source of receipts we have at the present moment, because we have practically no other traffic over the line but passenger traffic—have amounted in the whole to £19,403. We have received a small sum for transfer fees, rent of property, &c., bringing the total revenue for the half-year up to £19,637. We have received this by carrying 2,412,343 passengers. The number of passengers per train mile we have run is 17. If this were an ordinary railway that would be a very large number, because the general average of the large English railways is only about 3½ passengers per train mile. The general average of all the railways—including the suburban lines—in this country is about five passengers per train mile. As I have said, we have carried 17, but then, ours is purely a Metropolitan line, costing very much more, and the traffic upon it is expected to be very much heavier than the ordinary railways of the country. Now, you may say, Is your capacity for carrying the traffic at its maximum? No, with our existing train service we could carry three times the present number of passengers if we had them to convey spread over the whole of the 24 hours. Therefore, we have capabilities of development even in our present system of working—with the present number of trains we run. We propose, however, and hope before long to be running more trains, and if the traffic goes on, as we hope, steadily, we shall be able to take a very much larger number of passengers than even our full capacity now may be. Our earnings per train mile have been 2s. 9d. Of course, the earnings per train mile on a line of this kind ought to be larger than on an ordinary railway. Unfortunately, however, that is not at present the case, because we are not carrying the relative traffic to those railways that we ought to carry. The average receipts from passengers, pure and simple, apart from parcels and mails, carried by passenger trains on a line like the North-Western are 3s. 3d. per train mile against our 2s. 5d. Some of the railways, of course, earn more than 3s. 3d., and all the large railways benefit, of course, by the receipts which they get from other things which are carried by passenger trains—for instance, parcels, horses, carriages, mails, and things of that description. As regards our expenses, they have been, as stated in our report, heavier in the past half-year than the rate at which we are now working. In the early stages it was necessary that we should have a very large staff to deal with a traffic which was unknown and new, and we also had to have expensive men to educate the staff on a new system of this character. A considerable reduction has been made in the expenditure, and we are now working at a much less rate than we were in the early days of the concern. That, of course, is one of the pleasant features in the future. We have, of course, yet to learn what the cost of maintenance of our stock will be. It is all new now. I do not think it is likely to turn out that we shall have a very heavy item for maintenance. In our experience so far our permanent-way expenses are not likely to be as great as those of ordinary railways. Our locomotive power is the one point which, at the present moment, compares unfavourably with the ordinary working of a steam railway; but I would venture to caution you against taking the amount which at present appears in our accounts under "locomotive and generating power" as a permanent and absolutely ascertained figure. It has been difficult, especially in the early part of the half-year, to distinguish what was the permanent charge in that respect, because our motive power is used for various other purposes besides that of working the locomotive power itself, and the absolute division between these two in the half-year is not an ascertained fact. In future we hope to have it an ascertained rather than an estimated fact, and we shall deal more accurately with these matters in future half-years than we can do now. The expense of running has been about 11d. per train mile in the present accounts. That compares with charges on an ordinary railway, varying from 9½d. to 1s., so that we may be said to be not far from on a par in the past half-year with the ordinary charge per train mile of an ordinary steam railway; but, of course, our trains are very much lighter, and will not carry so many passengers as a train on a steam railway. As, however, we carry as many passengers at the present moment as we have to carry (we do not send any away), we are not losing anything by having smaller trains, and I am not sure that in the future the system we shall adopt of running light trains more frequently will not prove more economical and more conducive to the public convenience than running heavier trains, as on an ordinary railway, many of which run comparatively empty. We have had to contend in the past half-year with a good many difficulties. We are trying steadily to overcome them. They are not serious difficulties any of them, but, although small, the improvements which we are making, and hope to make, will, I think, render the railway much more popular when they are carried out than it has been in the past. At the same time, anyone who has used the railway will, I think, feel that as far as comfort, speed, and all the general accessories of convenient railway travelling are concerned our line is really not inferior to that of any of the ordinary steam railways. We hope in

Digitized by Google

future to make it very much superior, and I believe that, when all our improvements are carried into effect, it will be confessed that we have brought into use a system of locomotion which will be a decided improvement upon what has hitherto been in existence. The great stage coaches of the past had their day, and were efficient in their day, which lasted for some 60 years. They were superseded by the steam railways, which have had their day, and have lasted up to the present time for another 60 years. It remains to be seen now whether, after all, the time has not arrived when some new departure ought to be made in our locomotion. Whether electricity is the mode and is to be the new departure has, I think, yet to be proved, but we have the satisfaction of knowing that, at all events, we have tried to do something towards the development of an improvement in the future, and I hope it will not only prove a success as regards public convenience, but that the time will come when I shall be able to congratulate you upon its being a financial success also. The improvements which we are making are in various directions. We have had two new trains of carriages built. They are now on the ground and are being put together ready for working, and I think that they will be a decided improvement on the old ones. We have two locomotives building which we also believe will improve the speed and regularity of the trains. The lighing of the trains is having our special attention, and half the trains are now lighted on an improved principle, which, I think, will be still further developed. It is the electric light. Hitherto it has been, as you know the electric lighting very often is, an uncertain matter; I think we are now making it into a certain and fixed light that will be thoroughly satisfactory for the purpose. We have just placed two new boilers in position, so as to give us additional power. We have a new engine and a new dynamo nearly ready for delivery, and before long we shall be in a position to cope with the traffic which comes to us—as, unfortunately, all suburban traffic does come—in an irregular manner, that is to say, in the morning and evening you have a certain crush of people, while in the middle of the day we should be glad of more passengers than we now carry. We hope to get our increase of traffic, first, from disabusing the public mind of the prejudice which exists at present very largely against travelling by an underground railway of this description. When the Metropolitan Railway was first opened, those who recollect it will remember how very strong was the prejudice against travelling underground. People have got over that prejudice, but, with a railway two stories underground and working with a power so little known as electricity, there is, naturally, on the part of the timid section of the public a great deal of prejudice to be overcome. I believe that when we have everything in order we shall overcome that prejudice, and that our traffic will steadily increase. We hope, also, to get—and we are getting, in fact—an increase of traffic from the growth of population on the route. The houses that were formerly unoccupied are now being occupied. New houses are being built in consequence of this line coming in that direction, and, in addition, all railway companies find that increased facility to the traffic produces increased traffic. Therefore, we have every hope that this line, as other railways, will steadily grow in traffic and increase; and as I think our expenses will not grow in the same proportion as they do in the case of an ordinary steam railway, we have, I think, some hope in the future, though, unfortunately, it is hope deferred at the present moment; and I am not able, as I should have liked to do at our first meeting, to declare a dividend. As I have stated at previous meetings one of the most important questions that we have to consider is how to fill up the trains during the middle of the day. We have made an effort to do that in certain cases in the last two or three months by reducing the fare from 2d. to a 1d. from certain stations at stated times. The result has been so far satisfactory. It has resulted in our carrying from those stations already three times the number that we carried before, and our receipts have increased from those stations some 50 per cent. Whether the decrease in the fares at other stations would produce like results is a question that we must consider very carefully. As long as our trains are full at 2d., it is not in the interest of the Company to reduce the fares. We regretted to have to alter the system of a perfectly uniform fare over the whole line, but still, however much you may be attached to a system, we felt that it was our duty in this matter to meet the varying circumstances of the day, and to try and increase the popularity of the line, and, concurrently, its receipts. We agreed to go to Parliament for an extension of this line through the City up to the "Angel" at Islington. That would have been a very good line in itself, and I think would have paid very well, and have brought to the existing line a very considerable increase of traffic exactly at the time we wanted it. Unfortunately circumstances occurred in the first Committee of the House of Commons which led the Committee to throw out the Bill. There was very slight opposition to the Bill itself. The only remaining opposition at last was that of the Corporation of London, and even they, I believe, did not wish or desire that the Bill should have been thrown out. However, circumstances arose in Committee, with which we have nothing to do, which probably induced the Committee to throw out that Bill. I question whether in our present financial position—at least it is very doubtful—we could come to you now with a recommendation for such an extension again. Until we have brought up the price of our shares on the market it might be doubtful if we could issue the capital, except at such a large discount that it would be undesirable to do so. However, between this and Parliament meeting we shall have to consider the question, and if we can see our way of carrying that through, without burdening the existing Company, we should much prefer to do it. The expenses of the Clapham extension remains as a separate item until we can see what is to be done with that matter. The new plant which we are putting down is intended as part of the plant that will work this extension, but the same reason that we do not propose immediately going for the Islington extension again will apply to our carrying out the Clapham extension at the present moment. We propose, however, to do certain things as part of that work which will be available for use on the present line, and which will also form part of the extension traffic in the future. You will see that the action taken by the London County Council (to contest the right of the Company with respect to the line of frontage at Kennington and the Oval stations) ended in our success. It was a very arbitrary action, having no good case as regards ourselves, but really having for its object the testing of particular rights, which they thought they could try with a small company like this with more success than with a larger company. We felt that there was no alternative but to oppose their action, which we did successfully in the first Court, and on their appealing to the Court of Appeal the decision was confirmed in our favour.

Mr. SAMPSON HANBURY seconded the motion.

Mr. S. PETO hoped the Directors would seriously consider before going for any extensions. He thought from what the Chairman had said that it would be hopeless at the present time to raise new capital except on most disadvantageous terms. He saw that Mr. Robinson had resigned his seat at the Board, and that another gentleman had been elected in his place, but with such a small undertaking as theirs was it absolutely necessary to have five Directors. He thought there was no cause for despondency, and of course in such an undertaking they must hope for better things in the future.

The CHAIRMAN, in reply, assured Mr. Peto that the Directors were as anxious as that gentleman himself could be not to commit the Company to any expenditure that could be avoided. He did not think there was any likelihood of their going on with the Islington extension at present. As to the number of Directors, they were bound by the Act of Parliament, and they could not have less than five. Three was to form a quorum, and in the case of illness or absence of a Director, it was almost impossible to get this quorum unless there were five. He quite agreed with Mr. Peto, and was himself not in favour of a large Board, but there must be a sufficient number to make their working certain. Although the income of the Company was at the present moment very small, the work connected with it was not by any means small, and a great deal of constant attention and management was required.

The motion was carried unanimously. A vote of thanks to the Chairman and Directors was then proposed, seconded, and carried unanimously.

The CHAIRMAN, in reply, thanked them for their kind expression of confidence, and assured them that the Directors would do their best to deserve it.

The proceedings then terminated.

Liverpool Overhead Railway Company (Limited).

The half-yearly meeting of the Liverpool Overhead Railway Company was held on Wednesday, at Liverpool, Sir William Forwood in the chair.

The CHAIRMAN, in moving the adoption of the report, said the amount received on capital account was £163,035, of which £143,098 had been expended in works. They had made satisfactory progress during the past half-year. The main structure had been advanced south to the Collingwood Dock, and in the course of the work three important opening bridges had been made, The foundations were completed as far south as St Nicholas Church, and he expected that the structure would be advanced to that point by the end of September, or the beginning of October. During the past two months they had erected two miles of the main structure, and the contractor expects that the whole of the foundation for the southern section will be completed within four months. It was rather difficult to hazard an opinion as to when it would be completed, but he hoped that by next spring they would be within measureable distance of the completion of this important undertaking. During the past six months they had given serious consideration to the means of propulsion to be adopted. The Directors had visited various electrical works in the country, and they had seen the electrical railway now being worked in London. They also had the advantage of the advice of Mr. Greathead, the engineer of the railway passing under the Thames, and after careful consideration they had decided to adopt electricity, because it would be cheaper and safer and cleaner, and more economical in its working than steam. They had invited tenders, and they had selected the one sent in by the Electrical Construction Company, of Wolverhampton, with which they had entered into a contract to work the line for two years at 3½d. per train mile for locomotive expenses. The electricity would be generated at a central station, to be located near the Wellington Dock, a position which they had been fortunate enough to obtain from the Dock Board. By having their station at that point they could obtain water at an advantage, and they would also have the advantage of having their coal tipped from the railway overhead, without the necessity of constructing buildings, &c. In that way they would save a considerable amount of money. The electricity would be conveyed by a central rail to the motor cars which will compose the train, and the journey from end to end, including stoppages, will be made in 25 minutes.

Mr. BRANCKER having seconded the motion for the adoption of the report,

The CHAIRMAN, in reply to questions, said that the 3½d. per train mile covered the whole of what was known as the locomotive expenses of the line. It had been the intention of the Directors from the first to open the northten section as soon as it was completed; but a great deal would depend upon the completion of their electrical plant and generating station. In other words, the southern section was being proceeded with so rapidly that it might be completed by the time the electrical equipment was ready, and in that case all sections of the line would be opened together. The Directors did not at present contemplate manufacturing electricity for illuminating purposes, except for their own uses, and the line would be lit by electricity manufactured by themselves.

The report was unanimously adopted, and a vote of thanks to the Chairman concluded the proceedings.

Birmingham Central Tramways Company (Limited).

The annual meeting of this Company was held at the Queen's Hotel, Birmingham, on Wednesday, Mr. Joseph Ebbsmith (Chairman) presiding.

The report submitted by the Directors stated that the electric lines, which in the first half of the year were suffering from exceptional difficulties of construction and maintenance, have apparently overcome those difficulties, and show a substantial profit, which is steadily improving. The accompanying accounts showed that the electric car lines, since the opening of the lines on July 24, 1890, had run 138,396 miles, and carried 1,144,718 passengers, the receipts from that department being £8,372. 1s. 8d., against an expenditure of £5,711. 8s. 5d., giving a balance of £3,020. 13s. 3d. The cost per mile run on the four sections of the Company's lines for the year were :—Steam, 10·99d.; electricity, 9·90d.; horse, 9·79d. ; cable, 6·33d. The gross revenue account showed a balance, including £6,124. 7s. brought forward, of £31,782. 3s. 9d., out of which the Directors proposed to place £10,000 to reserve, to pay a dividend of 4 per cent. on the ordinary shares, carrying forward, after payment of the dividend on the Five per Cent. Guaranteed Shares, the sum of £1,262. 3s. 9d.

The CHAIRMAN, having moved the adoption of the report, in the course of his speech, said that that meeting marked an epoch in the history of the Birmingham Central Tramways Company, for to all intents and purposes they had succeeded in carrying out those works of capital commitment which it was the duty of the present Board to accept at the time when they took office four years ago. It was well from time to time to take stock of the progress which was made ; and when they looked back on the dreary record, and when they considered how many of the shareholders and how many experts outside the Company were of opinion that it would not be possible for the Company to meet its engagements, he thought it was very satisfactory indeed to say that every contract to which they were committed at the time when they accepted office had been loyally fulfilled, and that the capital account of the Company was one for the future consideration of the shareholders, and that there were no rocks ahead of which they need take serious notice. The expense of maintenance of the steam engines had increased during the past year by 25 per cent., and almost the same ratio obtained between 1890-89. One cause of this great expenditure was increasing traffic, and it had been necessary that the engines should do an increasing amount of work. That increasing amount of work had meant an increased expenditure in maintenance ; that maintenance must continue, and he could not hold out to them any expectation that the cost of maintenance per engine would decrease. It was an expense which had to be faced, unless, indeed, the shareholders were prepared to recommend the policy of a very great addition indeed to the engine power, so as to enable them to run a proportionately decreased mileage with each engine. But that, to his mind, would not be sound policy. As Central shareholders, they were bound to look forward to the future, and they knew that steam traffic was but a question of time. It was useless to blink the fact that in future another form of traction would very probably obtain. But during the whole tenure of his office he had most scrupulously abstained from anything approaching to prophecy, and he bade them take this comfort home with them—that, having regard to the character of the main lines of the city, and having regard to the accounts of the cable department which were now before them, when the time arrived for the reconstruction of the form of traction haulage of the Company the present shareholders need not fear or doubt their own position. He did not advocate any rash or sudden change. They had had a period of strain in the past ; they asked for the consideration of the local authority and those in power during the period of rest and experiment, and during which they might obtain something like certainty with regard to the results of working any other systems. Whenever it did come it would be, in his opinion, an advance from solidity of position to prosperity, and not a case of injury to the ordinary shareholder by reason of the transformation.

In the course of the discussion which followed, the CHAIRMAN mentioned that the cost of the electric tramway in Bristol-road was, roughly speaking, about £30,000, whilst the cost of the cable lines was 50 or 60 per cent. more than this amount ; this was the cost of construction, but the question of working—a more intricate subject—must be borne in mind.

The Directors' report and recommendations were unanimously adopted, and Mr. Ebbsmith and Mr. Martin J. Smith, the retiring Directors, were re elected.

Johannesburg Gas Company (Limited).

The adjourned extraordinary general meeting of the shareholders of this Company was held, on Wednesday, at the Cannon-street Hotel, Mr. W. F. Lance presiding.

The CHAIRMAN proposed a resolution dissolving the Company, and forming a new company, to be called the Johannesburg Lighting Company (Limited) (which was given *in extenso* in our issue of July 17th), and said that this resolution was agreed to at a meeting on 15th July, but on account of the Directors having an insufficient number of proxies they were unable to declare it legally carried. They had now more than the requisite proxies, the shares represented numbering over 90,000, out of a total of 130.000. He wished to point out that although the total capital was mentioned as £250,000, the Directors hoped to keep it down to not more than £200,000, and to say that although, in consequence of people being out of town, the arrangements for carrying out the proposal set forth in the resolution had not yet been completed, he hoped they would be by October, to which month he would suggest that the meeting be further adjourned, in case of any unforeseen contingency arising.

The resolution was seconded by Mr. PARKER and carried unanimously, and the meeting was then adjourned until Thursday, 15th October

NEW COMPANIES, STATUTORY RETURNS &c.

ENDURANCE SEAMLESS TUBE AND VIAL COMPANY (LIMITED).—This Company has been registered by Waterlow Brothers and Layton (Limited), with a capital of £25,000 in £5 shares. Object : To carry on business as manufacturers of and dealers in weldless and other tubes. The first subscribers are :—A. Chamberlain, Birmingham ; G. Hookham, Birmingham ; P. Hookham, Birmingham ; W. Chamberlain, Birmingham ; J. Harrison, Handsworth ; J. A. Harrison, Handsworth ; H. Lane Edgbaston.

"ENGINEERING" (LIMITED).—This Company was registered on August 7, 1891, with a capital of £180,000, divided into 7,500 Five per Cent. Preference and 10,500 ordinary shares of £10 each, by Hyde, Tandy, Mahon, and Sayer (solicitors to the Company), 33, Ely-place, Holborn, E.C. The objects are : To purchase or otherwise acquire and take over as going concerns the business of proprietors and publishers of the newspaper or journal known as *Engineering*, carried on at Nos. 35 and 36, Bedford-street, Strand, W.C., and also the business of printers and otherwise, carried on at Bedfordbury, St. Martin's-in-the-Fields, under the style of the "Bedford Press."

AKESTER ELECTRO-MOTOR AND ACCUMULATOR COMPANY (LIMITED).—The annual return of this Company, made up to February 28, 1890, was filed on August 5, 1891. The Company, which was registered on May 16, 1887, has a capital of £5,000, in £1 shares ; 5,000 shares have been taken up, upon 1,500 of which 16s. per share has been called, while the remaining 3,500 shares have been considered as fully paid. The calls paid amount to £1,000, and unpaid to £112. The Company's offices have been changed from 50, Holborn-viaduct, E.C., to 36, Great James-street, Bedford-row, W.C. (filed on July 29, 1891).

CHILI TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to July 28th, was filed on August 4, 1891. The Company, which was registered on June 28, 1889, has a capital of £250,000 in £5 shares ; 40,000 shares have been taken up, the full amount called and all calls paid. Office : 42, Old Broad-street, E.C.

DEVON AND CORNWALL ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The final order for the winding-up of this Company (which was registered on May 12, 1882, with a nominal capital of £100,000 in £5 shares), upon the application of Alfred A. James, its official liquidator, was granted by Justice Chitty on July 24, 1891, and a notice filed on August 5, 1891.

HEAD, WRIGHTSON, AND COMPANY (LIMITED) (Engineers, Shipbuilders, Electricians, and Contractors).—The annual return of this Company, made up to July 4, 1891, was filed on July 14, 1891. The nominal capital is £210,000, in £5 shares. The Company was registered on June 21, 1891. All the shares have been taken up, and upon 28,001 the full amount has been called and paid, and upon the remainder the full amount has been considered as paid, the calls paid amounting to £140,005, while £69,995 is considered as paid. The total amount for which share warrants, comprising 500 warrants of 1 share each, 200 warrants of 5 shares each, 150 warrants of 10 shares each, and 100 warrants of 20 shares each, amounting to 5,000 shares, are outstanding, is £25,000. Office : Teesdale Iron Works, Stockton-on-Tees.

HOUSE-TO-HOUSE ELECTRIC LIGHT SUPPLY COMPANY (LIMITED).—At an extraordinary general meeting of this Company, held at the Central Electric Lighting Station (Kensington), Richmond-road, S.W., on July 7, 1891, the following special resolution was duly passed, and at a subsequent meeting held on July 24, 1891, duly confirmed :—"That clause 115 of the Articles of Association (which reads as follows :—'Any casual vacancy occurring in the Board of Directors may be filled up by the Board, but any person so chosen shall only retain his office so long as the retiring Director would have retained the same if no vacancy had occurred') be struck out, and the following be substituted :—'The Directors may at any time appoint any qualified person as a Director, either to fill up a casual vacancy, or as an addition to the Board ; but so that the number of Directors shall not at any time be more than the maximum number hereinbefore mentioned, or such reduced number as may from time to time be fixed by the Company in general meeting, provided that any person so appointed shall hold office only until the next ordinary general meeting.'" This notice was filed on August 8, 1891. Office : 117, Bishopsgate-street Within, E.C.

MANCHESTER EDISON SWAN COMPANY (LIMITED).—The annual return of this Company, made up to the 29th July, was filed on August 4, 1891. The Company, which was registered on May 24, 1882, as the "Manchester and District Edison Electric Light Company (Limited)," has now a nominal capital of £550,000, divided into 50,000 "A" shares of £9 each, and 10,000 "B" shares of £10 each ; 20,000 "A" shares have been taken up, and £1 called and paid upon each share, and the whole of the "B" shares have been taken up, and the full amount called and paid, the calls paid amounting to £120,000. Office : 14, St. Ann's-square, Manchester.

LANCASHIRE AND YORKSHIRE ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company, made up to July 9, 1891, was filed on August 5, 1891. The Company, which was registered on November 4, 1882, has a nominal capital of £100,000 in £5 shares ; 127 shares have been taken up, upon each of which £2. 10s. per share has been called. The calls paid amount to £315, and unpaid to £2. 10s. Office : 6, St. James's-square, Manchester.

NEW TELEPHONE COMPANY (LIMITED).—The following was filed on July 25, 1891 : In the High Court of Justice, Chancery Division, Mr. Justice North. Upon the petition of S. P. Thompson, of the Technical Insti-

tute, Finsbury, and E. Garcke, of Victoria Works, Belvedere-road, Lambeth, on June 3, 1891. This Court doth order that all further proceedings in relation to the winding up of the Company be stayed. The offices are now situate at 90, Cannon street, E.C. (Filed August 7, 1891).

WILLIAMSON ELECTRICAL AND ENGINEERING COMPANY (LIMITED).—The capital of this Company, which was originally £5,000 in £10 shares, has now been increased to £25,000 by the creation of 2,000 new shares of £10 each, and the notice of such increase filed on July 31, 1891. Office: 14, St. Ann's-square, Manchester.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the weeks ending July 31st and August 7th amounted to £4,251 and £4,243 respectively.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The traffic receipts of this Company for the week ended July 31st amounted to £821.

MANGANESE BRONZE AND BRASS COMPANY (LIMITED).—A meeting of this Company was held on Thursday, at the offices, 73, Lombard-street, E.C., but the proceedings were private.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended August 7th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,680.

WESTERN COUNTIES AND SOUTH WALES TELEPHONE COMPANY. The half-yearly warrants for dividend to June 30th last on the Preference shares of this Company, at the rate of 6 per cent. per annum, were posted on Saturday, the 8th inst.

WOODHOUSE AND RAWSON UNITED (LIMITED).—The Stock Exchange Committee have appointed to-day (Friday) a special settling day in this Company's ordinary shares (Nos. 1 to 31,436) and preference shares (Nos. 40,001 to 59,946 and 61,765 to 61,800), but have refused a quotation in the Official List.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 692.—Vol. XXVII. FRIDAY, AUGUST 21, 1891. Price Sixpence.

NOTES.

The early date of the sixty-first meeting of the British Association, which opened at Cardiff on Wednesday, has accentuated the usual lack of information with regard to the Papers to be read. In Section A, Prof. W. Stroud will make "Some Revolutionary Suggestions on the Nomenclature of Electrical and Mechanical Units," and Mr. Preece will give us some further information on "The Magnetic Quality of Different Steels, and on Modes of Tempering," a complex subject, which was briefly dealt with in our columns a few weeks ago by Prof. Silvanus Thompson. Mr. F. T. Trouton will describe some experiments on "The Rate of Propagation of Magnetisation in Iron;" and Prof. D. E. Jones, of the Aberystwith College, is down for a Paper "On the Damping of Electric Waves along Wires," while Prof. Silvanus Thompson and Mr. Swinburne will each have something to say about standard cells. In Section G we may expect a little information with regard to the working of the London-Paris telephone line from Mr. Preece. Mr. A. R. Bennett will read two Papers, one on "The Telephoning of Great Cities" and another on "An Electric Parcel Exchange System;" and Prof. George Forbes will sum up our "Recent Progress in the Use of Electric Motors." A by no means striking programme. The British Association is, however, fruitful of surprises, and, although verging on the great climacteric, it frequently exhibits signs of youthful vigour, so that, in spite of outward and visible signs to the contrary, the Cardiff meeting may yet develop into a success from the electrician's point of view.

"The strange and startling rumour" which was said to have been in the air about this time last week, to the effect that Mr. Ferranti had severed his connection with the London Electric Supply Corporation and had left the country, probably originated from the fact that Mr. Ferranti had left *for* the country (a not unusual proceeding in August) and that his agreement with the Corporation terminated in due course at the beginning of the present month.

It was pretty evident from the tone of the Chairman's speech at the meeting of the shareholders of the London Electric Supply Corporation, last March, that as soon as everything was complete in connection with the present 90,000 light plant installed at Deptford, the first constructive period was to be considered at an end, and severe economies were to be effected. "We are now," the Chairman then said, "going to be mighty prudent, that is to say, before entering on the next stage of our operations, the stage which will complete and develop 200,000 more lights, we shall want some more money. I do not think we shall get it myself, or I do not think I shall have any hard in trying to get it, until we have established the first stage as a profitable commercial undertaking, because if you were to attempt to raise more money until that is tested, you could only raise it on disastrous terms." In consequence of this prudent determination here foreshadowed the engineering staff of the Corporation has been re-organised, with the result that it has been found possible (now that everything is working smoothly) to allow Mr. Ferranti to relinquish his responsible position of Chief Engineer.

We are glad to hear that more than 30,000 lights are now connected to the Deptford system, and that the Siemens and Fowler-Waring concentric cables, which have given entire satisfaction, have everywhere been substituted for the old overhead distributing network, now a thing of the past. Four transformer sub-stations are at present in regular operation—namely, the Grosvenor Gallery, Blackfriars, Trafalgar Square, and Deptford.

The difficulty in arriving at any definite information as to the cost of electric traction in this country, as compared with other systems, has been due to the fact that it has not been carried out on a sufficiently extensive scale. On another page, however, will be found an analysis of the accounts of the steam, horse, cable, and electric tramways worked by the Birmingham Central Tramways Company. At present the steam trams are carrying 58·5 per cent. of the passengers, while the cable takes 21·5 per cent., and the horse cars take 15·4 per cent., the electric trams only accounting for 4·7 per cent. of the whole number of customers. But, in spite of this very small proportion, the figures are extremely favourable to electricity. The proportion between the passengers carried by horses and by electric traction is as 100 is to 30·4, but the proportion between the balance carried to revenue in these two systems is as 100 is to 92, showing greatly to the advantage of electricity. This is partly explained by the first table, in which it appears that the electric trams carried nearly once and a-half as many passengers per car-mile as the horse trams and omnibuses, while the expenses per car-mile differ by only one per cent. The profit per car-mile for electric traction was more than four times that of horse traction; but interest on capital not being

Digitized by Google

taken into account, and the depreciation being of a different kind, the actual figures cannot be accepted as representing the actual earnings.

PERHAPS the most satisfactory and encouraging part of the analysis is that which deals with the working expenses, for these are not affected by accidents of fares and districts. The skilled labour naturally burdens the electric system, but steam is only 21 per cent. lower, and horse traction offers a saving of only 6 per cent. in wages. The electric trams show a saving of 12½ per cent. over the steam trams in cost of fuel, and 55½ per cent. over the cost of forage and bedding. The repairs for electric cars were higher, but the expenses of permanent way were much lower than for steam. The general charges for steam and for electricity are identical, and the total expenses differ in favour of electricity by about 10 per cent., while horse traction is about 1 per cent. cheaper than its latest competitor. All the above comparisons are very encouraging, considering that only some half-a-dozen cars have been running for a twelvemonth, and it appears highly probable that if all three systems were carried out on an equal scale and under similar conditions the further saving of wages and fuel would amply provide for the wear and tear of battery plates, and leave a handsome balance in favour of electric traction. We hope that next year full information will be given as to capital charges, and that depreciation will be allocated to the different departments, so that a more strict comparison may be made.

IN our issue of the 7th inst. we alluded to two matters connected with photometry, the one raised by the gas companies, who ask the Board of Trade for more uniformity in the instruments which are "used against them," and the other by the County Council, who call for a more satisfactory standard of light. The first of these, and the one which is of comparatively small importance or interest to science or to engineering, has been met by a "Memorandum as to Photometers," issued by the Standards Department of the Board of Trade. It is announced that the Department will receive for examination and verification any photometer in use in connection with the sale of gas; but a certificate of verification will only be issued in respect of photometers of the Evans or Letheby forms. In our recent article we argued that the standard of light, as defined by the "parliamentary candle," was not provided, like a yard or a pound, as a standard to which buyers or sellers could refer, and still less can be said for these photometers, which are simply instruments for official testing of the quality of gas supplied. These may be compared to the chemical apparatus used by Dr. TIDY and Dr. FRANKLAND in their tests of the purity of our water supply. The Standards Department, on the other hand, have a very elaborate and accurate system of applying the standard of length to the determination of the cubic foot, and hence, by standard gas meters, to the verification o ordinary gas meters.

THE real cause of complaint about photometers seems to have been that ingenious improvements have been occasionally introduced by gas inspectors, and these may have been considered successful if they told against the gas companies. It is difficult to see what practical gain is effected. The Standards Department may be depended upon for verifying instruments only because they are really capable of enabling a skilled operator to make accurate comparisons; and they will not countenance any conventional or old-established method if not accurate. As nearly all photometric measurements, and certainly all of those under consideration, depend on the use of a balance or null method, the chief desideratum of a photometer is sensitiveness. The Memorandum, however, refers to the official verification of "the burner, meter, minute-clock, scale, governor, pressure-gauge, and other subsidiary measuring appliances." These have no interest whatever to the majority of our readers, and are connected with a rather clumsy attempt to provide a more convenient standard of light, and with the testing of gas rather than with photometers.

THE experiments of M. LEBLANC, which were described in a recent issue, makes the possibility of using paper and paraffin for the construction of condensers very hopeful. The success which he met in using thin ebonite does not appear to be so important, as the thickness is still too great, and the fact that the ebonite condensers stood 11,000 volts does not prove its superiority for practical purposes over such well-known, cheap, and easily-handled materials as paraffin and paper. Paraffin of great purity is commonly used for electrical purposes; its impurities are easily detected, and it can be well relied upon for not changing in any way with time. But there is hardly any material of which more varieties and qualities are to be found than paper, though, after experiments with a great number of kinds, Messrs. SWINBURNE and Co. only found one satisfactory sort. The "forming" process of M. LEBLANC, although supported, now that it has been hit on, by excellent theoretical reasons, was not likely to have been thought of deliberately, and was the result of a happy accident. Knowing the rubbish that is used in making paper, and the potent chemicals employed in inducing this rubbish to present a respectable appearance, we would hardly go so far as M. LEBLANC and say that one need not trouble oneself about the quality of the material so long as it undergoes the process of formation described. Continuity is the first essential, and homogeneity the second, while the process of formation is itself the best possible test of the finished article.

THE biography of Prof. VON HELMHOLTZ, accompanying the steel plate engraving published with the present issue, has been specially written for this journal by Prof. H. KRONECKER, of Berne, one of the great German *savant's* most successful pupils. We are indebted to Dr. GAMGEE, of Cambridge, for the admirable translation from the German. The concluding portion of the biographical sketch, dealing more especially with Prof. VON HELMHOLTZ's electrical work, will appear in our next issue.

Dublin.—The Town Council propose to replace their electric lighting licence of May 3, 1889, by a Provisional Order.

Belgrade.—The concession for the electric lighting of Belgrade has been secured by the firm of Tzikos, Pericles, and Caze.

Digitized by Google

Budapest.—At a recent meeting of the Town Council it was decided to replace about 20 per cent. of the existing gas lamps in the streets by the electric light.

University College, Nottingham. — The Session 1891-92 of this College begins on Monday, October 5th. The engineering department is in charge of Prof. William Robinson. For further particulars see our advertisement columns.

Bristol.—The Electric Lighting Committee of the Town Council have decided to request Mr. Preece to furnish them with a written report, giving his reasons for selecting the particular machinery recommended to the Committee.

Personal.—We are informed that Mr. G. E Hartmans has resigned his position as Assistant Engineer to Messrs. Crompton and Co., and has joined Mr. J. G. W. Aldridge, consulting engineer, of 9, Victoria-street, Westminster, and Southampton.

Hampstead Vestry.—The Hampstead Vestry has resolved to apply for a Provisional Order authorising it to introduce electric lighting for public and private purposes. The Vestry has, however, not yet decided whether to carry out the lighting itself or to place it in the hands of a company.

Telephonic Communication between Stockholm and Christiania.—The last Swedish Parliament granted a sum of 60,000 crowns for the purpose of extending the telephone to the Norwegian frontier, on the condition that Norway should bring her telephone wires to the Swedish border. According to Norwegian papers the Storthing has acceded to this condition, so that direct telephonic communication between Stockholm and Christiania will shortly be established.

Pendant Switch.—Inquiry.—We have been requested to ask through our columns if there is such a thing to be had as a reliable pendant switch composed solely of earthenware, or other incombustible and non-hygroscopic material, with the necessary metal parts. Two forms are required by our correspondent, one for attachment to, or in combination with, a bayonet socket lamp holder, and the other to hang on the end of a flexible cord separate from the lamp.

Accident at the Agricultural Hall.—On the 28th ult. an arc lamp, which was hanging over the entrance of the Agricultural Hall, gave way and fell on a little girl. At the inquest, the electrician in charge of the electric lighting plant at the hall attributed the accident to a leak, which resulted in the current going to earth through the suspending wire. As a result the wire was burnt clean through, causing the lamp to fall. The wire was found to be hot after the accident occurred. The lamp was not alight at the time.

Telephony Abroad.—According to a French contemporary, the Belgian Government is contemplating telephonically connecting all the *chief lieux de canton* and large *communes* throughout the country to their respective provincial capitals. In Luxemburg, it seems, this has already been done, and even the smaller *communes* have been connected up. The atmosphere of small States apparently favours telephonic development, Sweden, Belgium, and the Grand Duchy of Luxemburg leading the way in the matter of cheap and extensive telephony.

Institution of Electrical Engineers.—With reference to our comments on the new rules of this Institution, in a recent issue, we understand that Associates can vote on any question that does not affect the Articles of Association, while the Institution of Mechanical Engineers do not allow either their "Graduates" or their "Associates" this privilege. As regards the additional "entrance fee" required on transfer from one class to another by the Institution of Electrical Engineers, it is to be noted that in the case of the Institution of Civil Engineers, in which no such additional payment is demanded, the same large entrance fee (£10. 10s.) is paid both by an Associate and a Member.

The Edison Convention.—The annual convention of the Edison Illuminating Companies was held in New York, on August 11th, 12th, and 13th. The following reports were down for presentation:—Report of Committee on the prevention of damage from crosses of high tension circuits; report of the Committee on lightning protection, and the results of experiments at the laboratory on new forms of lightning arresters; report of Committee on grounding the neutral wire in three-wire systems; report of Committee on fuel gas. Amongst the Papers to be read were:—"Important Details in Underground Conductors," by Mr. Stevenson; and "Peculiar Features of the Edison Feeder System," by Mr. Wilson S. Howell.

The Electric Lighting of Odessa Harbour.—The Odessa Harbour electric lighting plant constructed by the Thomson-Houston International Electric Company was taken over on July 8th by the Russian Government. There are in regular working 64 2,000 c.p. arc lamps, and eight 125 c.p. incandescent lamps. The arc lamp-posts vary in height from 43ft. to 30ft. There have been used about 10 miles of armoured cable, manufactured by Felten and Guilleaume, and also about 1,000 yards of submarine cable, 126 sq. mm. in cross-section, steel wire armoured. Where the submarine cable joins the land cable a Thomson-Rice cut-out is placed, allowing the cutting out of the submarine cable in case of fault. The generating plant consists of four 35-light series-wound arc dynamos, driven by belting from two central valve condensing Willans and Robinson high-speed engines. The two boilers are supplied by the Babcock and Wilcox Company.

Pisa.—At a meeting of the Town Council, on July 22nd, the terms on which a concession for the distribution of electricity would be granted were settled upon. From the pamphlet of regulations published by the authorities we gather that the period of the concession will not exceed 30 years, a provisional deposit of £400 will be required, and the firm finally obtaining the concession will have to deposit £2,000 as security. The leads may be laid either underground or overhead; in the latter case they must not be within 23ft. of the ground level. In case of a partial breakdown, lasting over 15 minutes, a fine ranging from 4s. to £40, according to the quantity of energy affected by the interruption, will be imposed. Should two total cessations of the supply, lasting over 15 minutes, occur within 30 days, the fine on the second occasion will be £80. Any disputes that may arise will have to be referred to a committee of arbitration consisting of three members.

Manchester.—According to the *Manchester Examiner and Times*, "The Electric Lighting Sub-committee appointed by the Gas Committee of the City Council have had under their consideration the reports of several consulting engineers as to the proposed installation of the electric light in Manchester. They have decided to recommend the appointment of an electrical engineer, who will advise as to the best system of lighting to be adopted, and will also superintend the operations of the contractor whose tender may be accepted for the work. This gentleman will receive a commission on the cost of the scheme, as is customary in the case of architects. The Sub-committee recommend that the 'lower pressure' shall be adopted, but further details of the scheme will be arrived at after the engineer has been appointed. It is proposed to confine the operations of the Committee entirely to a street installation; no apparatus in the interior of houses will be supplied, and those who desire to take advantage of the installation will have to execute their own connections. In this respect the Committee's scheme differs materially from the ordinary commercial operations of electric lighting companies." As no electric supply company of any standing now undertakes the business of interior fittings, we are unable to see where the material difference referred to comes in.

Damage by Lightning.—In the volume of Bavarian meteorological observations for 1890, Dr. C. Lang (the Director of the Service) contributes, says *Nature*, an article on the "Secular Variations of Damage by Lightning and Hail." He points out that in almost all recent investigations the conclusions come to are that during the last 50 years damage by lightning has much increased, but this is not borne out by his inquiry, but is probably owing to more attention having been paid to the subject recently. The numerous impurities introduced into the air of towns from fire-places, &c., would make it probable that they would be more liable to damage than country places, but exactly the opposite is the case, the ratio of damage to buildings in towns to that in the country being 1 : 2. This result is possibly to some extent due to the more numerous lightning-conductors, and to railway lines in the towns. He finds that

Digitized by Google

the damage from hail shows a very probable connection with the period of sun-spot frequency, but the secular range of the former points more particularly to the influence of temperature, so that the curve of hail-frequency shows not only a minimum occurring with the 11-year sun-spot maximum, but also a period of about 35 years. The damage from lightning, on the other hand, does not show any connection with a secular range of temperature, but the minimum occurs with the maximum of sun-spot frequency. In other words, damage from hail seems to be more decidedly connected with terrestrial, and damage from lightning more with cosmical, influence.

Cornish Boilers.—In the course of the systematic tests of steam boilers undertaken by Mr. Bryan Donkin, jun., and Prof. A. B. W. Kennedy, an experiment was made upon three Cornish boilers in regular use by the East London Waterworks Company, which may be taken as exemplifying the performance of this class of steam generators when set and worked in good style, without an economiser. The experiment lasted from 8.50 a.m. to 6.50 p.m.; two of the boilers being fairly clean and the other rather dirty. The feed-water was taken from the hot well of the engine; and the furnace gases were sampled periodically at a point in the main flue where the products of combustion of all three furnaces united just before passing the main damper. The fuel used was the standard coal selected by Mr. Donkin for all the experiments. It is practically smokeless. In the present case the firing was done by the ordinary stokers. Each boiler was 30ft. long and 5ft. 9in. diameter, with a single flue 3ft. 6in. diameter, crossed by three Galloway tubes; the total heating surface of the boiler being 700 square feet. Rather thick fires were kept. The waste gases entered the chimney at a temperature of 485°F. The balance-sheet of the boilers showed that the heat accounted for in the water was 78·3 per cent., 14 per cent. going away in the furnace gases, and 4·4 per cent. being lost by radiation. The equivalent evaporation per pound of coal as burnt from and at 212°F. was after the rate of 11·4lb. of water. The absolute steam pressure maintained was 51·7lb.

The Telegraph in China.—The Chinese, who have for a long period evinced a remarkable aversion to the construction of railways, have, says *Iron*, shown themselves scarcely less amenable to the establishment of telegraphic communication. The first telegraph put into work in China was constructed in the year 1866, during the Formosan war, and connected the island of Pagoda with the arsenal of Foo-chow. The concession for this line was granted to a foreign company by the Viceroy of the province of Foohkin. But the Government itself disapproved of the concession and threw various obstacles in the way of the Company with a view to prevent the completion of the line. Happily, however, for the progress of telegraphy, these subversive attempts of the Chinese authorities were frustrated, thanks chiefly to the powerful intervention of the various foreign ministers at that time resident in Pekin. In addition to the official harassment, the Company had to contend with the prejudices of the native peasantry, who regarded with no small animosity, mingled with distrust, this invention *du diable*, as they termed it; and it was only with the utmost difficulty that the Chinese Hodge could be induced to respect the wires. Since those eventful times the telegraph in China has been largely extended. There is a line from Pekin to Tientsin; another placing the capital in communication with the principal Manchurian towns, and continued to the Russian frontier, on the Amour and the Oussouri. The seven treaty ports on the Yang-tse-Kiang and the chief cities of the empire are connected between themselves and with the capital. A line from Canton has been extended in a westerly direction as far as Yunnan-Foo, capital of the province of Yunnan, near the borders of French Tonquin. Other wires have been laid between Foo-Chow and Canton, and between Port-Arthur and the capital of the Corea. The line which follows the valley of the Yang-tse-Kiang has stretched far into the interior of the country. As the result of a recent arrangement between the Chinese and Russian Governments, the native and Siberian lines unite in the valley of the Amour, thus securing direct telegraphic communication between Pekin and Europe.

Electric Apparatus for the London Fire Brigade.—The following extracts from the specification of work to be done and materials to be supplied in placing and maintaining in perfect order for a period of three years the electric bells, apparatus, working and fittings at all the Fire Brigade stations belonging to the London County Council may be of interest:—(*a*) The contractor is required to provide a telephone line between the chief station of the brigade and his office, by means of which requisitions for any work necessary will be transmitted to him, and all such requisitions reaching him between 8 a.m. and 5 p.m. must be attended to within two hours, and the work as far as possible carried out on the same day. (*b*) The cells are to be cleaned at least once in every six months, and from time to time as required, and recharged when necessary, and any new parts provided when required. (*c*) Any cell which on open circuit does not give at least 1 volt when tested immediately after ringing the bells connected to the battery of which it forms part for a continuous period of 30 seconds, must be at once renewed. The batteries must be maintained in such condition as to give not less than 8 volts at the terminals of the bells when all are ringing, unless a different figure shall be fixed by the chief engineer in any special case. (*d*) Bells are to be adjusted as requisite, and all bells ringing off the same battery are to have approximately equal resistance, and if the chief engineer shall so determine, existing bells which do not comply with this condition are to be replaced, and any bells which the contractor is unable or fails for 24 hours to put in perfect ringing order are to be replaced with new bells of approved kind. These will usually be required to have a resistance of from 45 to 50 ohms. (*e*) The automatic switches are to be adjusted and maintained to ring the bells to which they are connected for a continuous period of either 15 seconds or 20 seconds as directed. (*f*) All new insulators for outside wires are to be fluid insulators of approved pattern, the wires to be shackled off at each post or support. (*g*) All new posts are to be galvanised iron, with galvanised iron shoes and crossbars.

Electrical Subways in Brooklyn.—The final report of the Brooklyn Board of Commissioners of Electrical Subways, issued two years ago, still remains, says R.W.R. in the *Engineering and Mining Journal* of New York, the best summary statement of the municipal problem with which it deals. In one noteworthy particular the opinion and prophecy of the Board have received a striking confirmation. I refer to the matter of the corrosion of lead in conduits of creosoted wood. This evil was at one time very threatening, and so important that, although it constituted the only serious objection to the use of such wooden conduits, it might have counterbalanced, if remedy had proved impracticable, all the great advantages of that material. One concern, at least, engaged in the manufacture of lead-covered cables declined to guarantee them if laid in creosoted conduits. The remedies suggested were two: the alloying of the lead with about four per cent. of tin, which, however, rendered the cables both more expensive and more difficult to manufacture; and the use of a fibrous covering, which was somewhat objectionable on other grounds. The Brooklyn Board, however, caused careful laboratory tests and analyses to be made, and announced in its final report that, in its opinion, the corrosive agent is "phenol, which, being highly volatile, either escapes from the wood in the process of seasoning, or could be expelled more rapidly, if required, by artificial means." The frequent occurrence of the phenomenon of corrosion in different cities was, no doubt, due to the haste with which underground conduits were everywhere constructed during that period of spasmodic reform under "scientific" legislation. Experience has proved that the Brooklyn Board was right. The two-year-old Brooklyn conduits do not now corrode lead—even pure lead—appreciably; and in some other cities where the authorities and electrical companies were almost ready, in a panic, to abandon the system, the simple lapse of time has cured the difficulty. The underground system in Brooklyn seems to be running so peacefully and successfully that it is never heard of. If the Legislature had not summarily abandoned the whole experiment, that city might now be a model in the extent, as it is confessed to be in the simplicity and perfection, of its subways.

THE HISTORICAL DEVELOPMENT OF THE INDUCTION COIL AND TRANSFORMER.

BY DR. J. A. FLEMING, M.A.

(Concluded from page 361.)

§ 20. Sir. W. Grove's Employment of Alternating Currents with an Induction Coil.—Shortly after the publication of the description of Wilde's magneto-electric generator, Sir W. Grove had the idea of exciting an induction coil with an alternating current. He accordingly applied an ordinary medical magneto-electric machine to the primary of a Ruhmkorff coil, first screwing up the contact breaker of the coil, so as to close the primary circuit, and cut out the condenser. He found to his surprise that he could get no secondary discharge at all. When, however, he opened the contact breaker, so as to place the condenser in series with the primary coil and the magneto-electric machine armature, he got sparks of about one-third of an inch in length between the ends of the secondary coil. Not being able himself to see fully the reason for this he appears to have shown or described the experiment to Clerk-Maxwell, who sent him the explanation of it. (See *Phil. Mag.*, Vol. XXXV., 5th series, 1868, p. 360.)

Maxwell pointed out that the reason why he obtained no sparks from the secondary circuit, when the condenser was short-circuited, and the magneto-electric machine was applied directly to the primary of the coil, was because the self-induction of the primary coil prevented the alternating electromotive force of the generator from developing any but a very small current in the primary coil. When, however, the condenser was thrown into series with the primary coil by opening wide the contact points, the capacity of the condenser annulled a great part of this self-induction of the primary circuit, and hence permitted the alternating E.M.F. of the generator to send a much larger current through the primary coil, and this was able to generate a very considerable secondary current and secondary electromotive force. The condenser neutralised in part the impedance of the primary circuit. In this same Paper, Clerk-Maxwell sketched out the mathematical theory of the shunted condenser in series with an inductive circuit as follows:—Let V_0 be the maximum value of the periodic electromotive force of the generator, and let R and L be the resistance and inductance of the primary circuit of the coil, and C the capacity of the condenser shunted by a non-inductive resistance, r, arranged as in Fig. 26. Then the following relations hold good:—Let v_1 be the potential difference of the condenser-plates at any instant, and let i_1 be the current through the primary coil, and i_2 the current through the condenser shunt. Also let I_1 be the maximum value of the current in the primary coil. If v_0 is the E.M.F. of the generator, then we may write

$$v_0 = V_0 \cos p t$$

as the expression for this instantaneous value of the E.M.F. in terms of its maximum value, where p stands for 2π times the frequency of the alternating current or electromotive force; also we can write

$$i_1 = I_1 \cos (p t + \alpha),$$

and

$$v_1 = r i_2.$$

Hence we have

$$C \frac{d v_1}{d t} = i_1 - i_2,$$

and

$$V_0 \cos p t + R i_1 + L \frac{d i_1}{d t} + v_1 = 0,$$

as equations true at any instant, and it is easy to deduce that the maximum value I_1 of the current in the primary is given by

$$I_1^2 = \frac{V_0^2 (1 + C^2 r^2 p^2)}{r^2 \{(1 - L C p^2)^2 + C^2 R^2 p^2\} + 2 R r + R^2 + L^2 p^2}.$$

If $r = 0$, that is, if the condenser is short-circuited, this reduces to

$$I_1^2 = \frac{V_0^2}{R^2 + L^2 p^2} \quad \ldots\ldots \quad (1)$$

If $r = \infty$, that is, if the shunt is removed, it reduces to

$$I_1^2 = \frac{V_0^2}{R^2 + \left(L p - \frac{1}{C p}\right)^2} \quad \ldots\ldots \quad (2)$$

In the case when $2 C L p^2$ is greater than unity, the value of I_1 given by (2) is greater than the value given by (1). Hence the primary current is *increased* by throwing into circuit a suitable condenser. If $C L p^2 = 1$ the expression for the current is reduced to

$$I_1 = \frac{V}{R},$$

or the current has the greatest value it can have, and the inductance of the primary circuit is entirely annulled by the condenser.

Maxwell thus pointed out the condition for obtaining the maximum primary current and the reasons why the interposition of a condenser of suitable capacity increases the primary current, and hence increases the secondary electromotive force to the point of creating very considerable sparks between the secondary terminals.

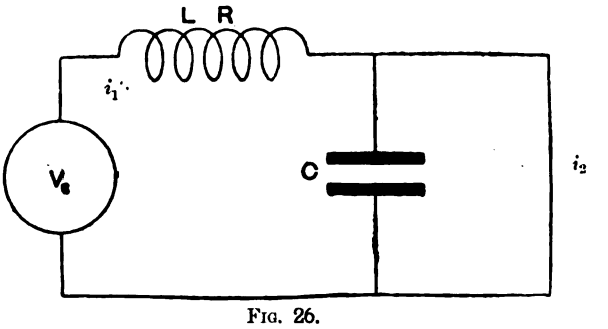

FIG. 26.

§ 21. Mr. Apps' Large Induction Coils, the Polytechnic Coil, and Mr. Spottiswoode's Great Coil.—In the years since 1867, Mr. A. Apps has devoted great attention to the production of large induction coils, and has been the designer and constructor of some of the most powerful coils in existence. Mr. Apps began by making coils of single flat spirals of wire insulated by discs of insulating material, but finding this construction too expensive, he adopted a modified form of the sectional winding. In 1869 he built the large Polytechnic coil, sometime exhibited and used at the old Polytechnic Institution of London. The secondary wire of this coil was 150 miles in length. The diameter of the wire was ·014 of an inch, and it was silk-covered. This secondary wire was wound in grooves about ⅛ of an inch in width and 200 in number. The iron core was a bundle of soft iron wire, 4in. in diameter, weighing 123lbs., and about 5ft. in length. The primary bobbin weighed 145lbs., and consisted of 6,000 turns of covered copper wire ·095 of an inch in diameter and 3,770 yards in length. The secondary bobbin when complete had an external diameter of 2ft. and a length of 4ft. 10in. The primary coil was insulated from the secondary coil by an ebonite tube. Excited by the current from 40 large Bunsen cells, this coil would give secondary sparks 29in. in length, and could in a few seconds charge 66 Leyden jars, each having 11 square feet of internal coated surface. The secondary discharge could pierce blocks of glass 5in. in thickness. The secondary sparks were of considerable thickness and apparent volume, and accompanied by a kind of flame. The next coil of any importance was an 18in. spark coil made for the late Mr. Spottiswoode, which was made on the same general lines as the Polytechnic coil. After introducing many improvements, Mr. Apps began, in 1876, to construct his most important induction coil, viz., the colossal induction coil built for the late Mr. Spottiswoode, which is described as follows in the *Philosophical Magazine* for January, 1877, p. 30, and which was used by Mr. Spottiswoode in many of his researches. It is thus described in the above-mentioned periodical by Mr. Spottiswoode himself:—

"The general appearance of the instrument is represented in Fig. 27, by which it is seen that the coil is supported by two

Digitized by Google

massive pillars of wood, sheathed with gutta-percha, and filled in towards their upper extremities with paraffin wax. Besides these two main supports, a third, capable of being raised or lowered by means of a screw, is placed in the centre, in order to prevent any bending of the great superincumbent mass. The whole stands on a mahogany frame resting on castors.

"The coil is furnished with two primaries, either of which may be used at pleasure. Either may be replaced by the other by two men in the course of a few minutes. The one to be used for long sparks, and indeed for most experiments, has a core consisting of a bundle of iron wires, each ·032in. thick, and forming together a solid cylinder 44in. in length and 3·5625in. in diameter. Its weight is 67lbs. The copper wire used in this primary is 660 yards in length, ·096in. in diameter, has a conductivity of 93 per cent., and offers a total resistance of 2·3 ohms. It contains 1,344 turns wound singly in 6 layers, has a total length of 42in., with an internal diameter of 3·75in. and an external of 4·75in. The total weight of this wire is 55lbs.

"The other primary, which is intended to be used with batteries of greater surface, *e.g.*, for the production of short thick sparks, or for spectroscopic purposes, has a core of iron wires ·032in. thick, forming a solid cylinder 44in. long and 3·8125 in diameter. The weight of this core is 92lbs. The copper wire is similar to that in the primary first described, but it consists of 504 yards wound in double strand forming three pairs of layers, whose resistances are ·181, ·211, ·231 ohm respectively. Its length is 42in., its external diameter 5·5in., and its internal 4in. Its weight is 84lb. By a somewhat novel arrangement, these three layers may be used either in series as a wire of ·192in. thickness, or coupled together in threes as one of ·576in. thickness. It should, however, be

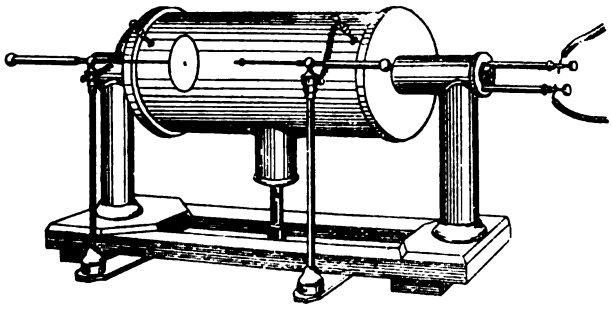

Fig. 27.—Mr. Spottiswoode's Great Induction Coil, made by Mr. Apps (1876).

added that, owing to the enormous strength of current which this is capable of carrying, and to the highly insulated secondary coil being possibly overcharged so as to fuse the wire, this larger primary is best adapted for use with secondary condensers of large surface, for spectrum-analysis, and for experiments with vacuum tubes in which it is desirable to produce a great volume of light of high intensity, as well as of long duration at a single discharge. The alternate discharges and flaming sparks can also be best produced by this primary. It has been used for high-tension sparks to 34in. in air, the battery being 10 cells of Grove's with platinum plates 6¼in. × 3in. Great facilities for the use of different sets of batteries are afforded by the division of this primary into three separate circuits, to be used together or separately; and by a suitable arrangement of automatic contact breakers, the primary currents may be made to follow in a certain order as to time, duration, and strength, with effects which, when observed in the revolving mirror, will doubtless lead to important results in the study of striæ in vacuum tubes.

"The secondary consists of no less than 280 miles of wire, forming a cylinder 37·5in. in length, 20in. in external and 9·5in. in internal diameter. Its conductivity is 94 per cent., and its total resistance is equal to 110,200 ohms. The whole is wound in four sections, the diameter of the wire used for the two central sections being ·0095in., and those of the two external being ·0115in. and ·0110in. respectively. The object of the increased thickness towards the extremities of the coil was to provide for the accumulated charge which that portion of the wire has to carry.

"Each of these sections was wound in flat discs; and the average number of layers in each disc is about 200, varying, however, with the different sizes of wire, &c. The total number of turns in the secondary is 341,850.

"The great length of the wire necessary can be easily understood from the fact that near the exterior diameter of the coil a single turn exceeds 5ft. in length. The spark, it is believed, is due to the number of turns of wire, rather than to its length, suitable insulation being preserved throughout the entire length. In order to ensure success, the layers were carefully tested separately and then in sets, and the results noted for comparison. In this way it was hoped that step by step safe progress would be made. As an extreme test, as many as 70 cells of Grove's have been used, with no damage whatever to the insulation.

"The condenser required for this coil proved to be much smaller than might at first have been expected. After a variety of experiments, it appeared that the most suitable size is that usually employed, by the same maker, with a 10-inch-spark coil—viz., 126 sheets of tinfoil 18in. × 8·25in. in surface, separated by two thicknesses of varnished paper, the two thicknesses measuring ·011in. The whole contains 252 sheets of paper 19in. × 9in. in surface.

"Using the smaller primary, this coil gave with five quart cells of Grove, a spark of 28in., with 10 similar cells one of 35in., and with 30 such cells one of 37·5in. and subsequently one of 42in. As these sparks were obtained without difficulty, it appears not improbable that, if the insulation of the ends of the secondary were carried further than at present, a still longer spark might be obtained. But special adaptations would be required for such an experiment, the spark of 42in. already so much exceeding the length of the secondary coil.

"When the discharging points are placed about an inch apart, a flowing discharge is obtained both at making and at breaking the primary circuit. The sound which accompanies this discharge implies that it is intermittent, the time and current spaces of which have not as yet been determined.

"With a 28in. spark, produced by five quart cells, a block of flint glass 3in. in thickness was in some instances pierced, in others both pierced and fractured, the fractured pieces being invariably flint glass. If we may estimate from this result, the 42in. spark would be capable of piercing a block 6in. in thickness.

"When used for vacuum tubes this coil gives illumination of extreme brilliancy and very long duration: with 20 to 30 cells and a slow-working mercury break, giving, say, 80 sparks per minute, the striæ last long enough for their forward and backward motion to be perceived directly by the unassisted eye, The appearance of the striæ when observed in a revolving mirror (as described in the *Proceedings of the Royal Society*, Vol. XXV, p. 73) was unprecedentedly vivid, and this even when only two or three cells were employed.

"Further experiments have shown that with such large coils only the newly discovered effects of very high temperature-combustion or volatilisation can be produced. On exciting the primary of the coil with a suitable dynamo-electric machine, or battery, and using a large Leyden jar in the secondary circuit (according to Sir William Grove's experiment), the electrical discharge passing between electrodes placed before the slit of the spectroscope lines and bands may be observed to advance and recede according to the variations made in the magnitude of the exciting discharges. As the atmospheric pressure may be assumed to remain constant, these effects are probably due to differences of temperature arising from the action of a greater or smaller extent of electrical effects on the electrodes in a given time."

Following on this great coil Mr. Apps has made many others, such as the 20in. spark coil made for the Framjee Kawasjee Institute of Bombay, and by certain devices of insulation has increased the length of the secondary spark beyond the length of the bobbin, thus making a bobbin of 8½in. in length give an 11in. spark. As an illustration of this fact Mr. Apps has, by permission, furnished the author with the details of six coils made for Lord Armstrong, the measurements of which are as follows:—

Digitized by Google

The secondary circuit consists of 8 miles 25 yards of silk-covered copper wire, ·0064in. in diameter. It makes 41,425 turns, and weighs in all 7lbs. 1oz. 7drs. The secondary circuit resistance is 12,500 ohms. The interior diameter of the secondary bobbin is $3\frac{5}{16}$in., the exterior $5\frac{7}{16}$in., and the length $8\frac{5}{8}$in. The secondary spark is from $10\frac{1}{4}$in. to 11in. in length. The primary coils consist of square copper wire, No. 14 B.W.G., the length of wire on each bobbin being 51 yards, laid on in four layers of 366 turns. The primary coil resistance is ·32 ohm. The length of the primary coil is 9·1in.; the outside diameter of the bobbin is 2in., and the

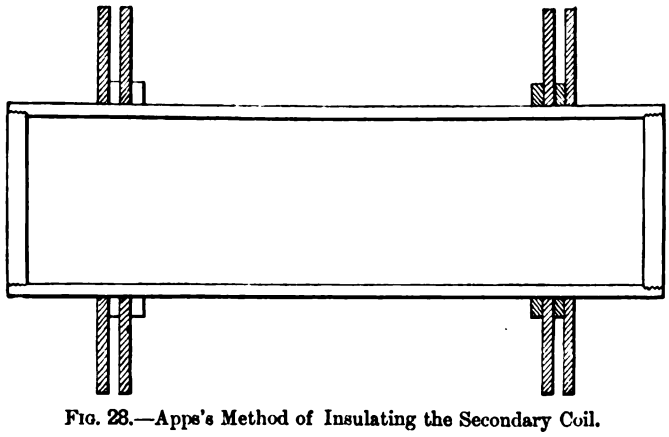

Fig. 28.—Apps's Method of Insulating the Secondary Coil.

inside diameter 1·6in. The most effective primary current is a current of 12 amperes and 10 volts. Each coil is fitted with a condenser divided into six parts. The details of the processes by which these remarkable achievements in insulation are produced are of the nature of trade secrets, but generally it may be said that the greatest precautions have to be taken to secure the result. Mr. Apps has obtained a high reputation by the excellent performance of many of his coils.

Some of Mr. Apps's improvements in induction coils are described in his British Specification, No. 177, of January 24, 1867. In this he gives the details of improvements in

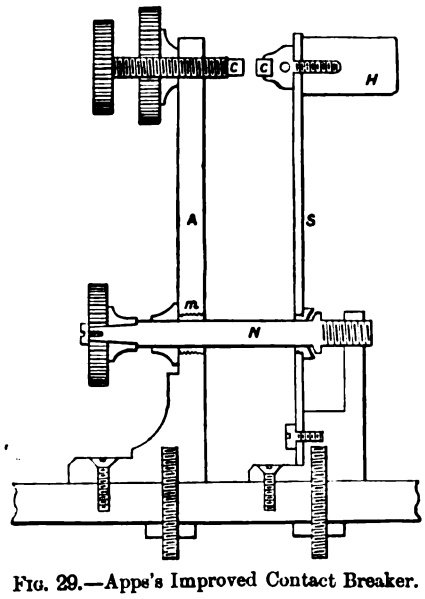

Fig. 29.—Apps's Improved Contact Breaker.

the mode of insulating the secondary coil, and in the construction of the contact breaker. His method of obtaining high insulation between the primary and secondary coil is as follows:—The primary coil is wholly enclosed in an ebonite tube (*see* Fig. 28), which projects beyond the secondary coil for some distance. On this ebonite tube are slipped, alternately, a series of ebonite discs and ebonite rings, which act as distance pieces separating the discs, and thus form a series of narrow grooves or compartments in which the secondary coil is wound. The secondary coil is then laid in these grooves, each section being carefully insulated and tested, and the several sections joined up so that no two portions of the wire which come very near to each other are at very different potentials. Besides greatly improving this groove mode of winding, Mr. Apps devoted attention to the contact breaker. He gave it the form shown in Fig. 29. In this figure S is the spring which carries the hammer head H. The pillar A is perforated and bushed at *m* with an insulating collar, and a tightening screw, N, serves to press back the hammer spring, if desired, so that the platinum contacts, *c*, *c*, are pressed more tightly in contact, and the time of vibration of the spring, S, is increased. This enables the rate of break to be altered even during the working of the coil. Mr. Apps has devised a form of multiple contact break which renders it possible to divide the break spark between several points.

It cannot be said that any subsequent improvements have been made which have altered for the better the mode of construction adopted by Mr. Apps for the construction of the induction coil since his chief large coils have been made. Other makers have introduced little changes of arrangement, but the essential features in all good coils remain the same, and even the general form of the coil is not much varied. Some changes of manufacture have been introduced, such as that in Pyke and Barnett's induction coil (*see* Fig. 30). In this coil the hammer break is erected on the top of a vertically placed coil. The hammer is mounted on a short thick spring and is

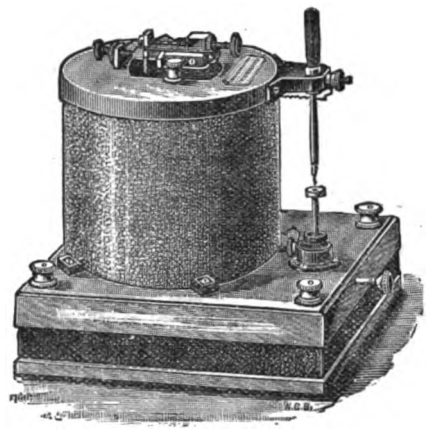

Fig. 30.—Pyke and Barnett's Induction Coil.

rapidly vibrated by an auxiliary electro-magnet, the exciting coils of which are in a shunt circuit to the main primary coil. The main coil contacts are so mounted that their normal position is in contact, one of them being carried on a spring. The vibrating hammer in its excursion strikes against one of these contacts and separates them slightly and instantaneously, thus interrupting the circuit of the primary coil.

The whole of the parts are arranged for ready and rapid adjustment. The discharging terminals of the secondary circuit are arranged at the side of the coil in a convenient manner.

A California Mining Plant.—The Dalmatia Mine is situated in the California Mountains, 1,500ft. above the sea, and nearly 60 miles from Sacramento. Fuel being dear, the question of obtaining power for operating the mine was a serious one. After deliberation it was decided to install an electric plant. The nearest water is Rock Creek, a stream running into the American River. The creek was tapped about two miles above the point where it empties into the river, and the water was then led through ditches dug and blasted through the rock to a point about 100ft. above the river. The power station is placed close to the river, and the water is led into it through a 28in. iron pipe. At the power-house is installed a large Pelton waterwheel, driving a jack shaft, to which is belted a Brush compound generator, giving 1,800 volts and 40 amperes. The current is taken by an overhead copper wire over the mountains to the mine, one and a-half miles distant, where the motor equipment is situated, driving the stamps and other mining machinery.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*" *All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

'THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

SUBSCRIPTION RATES.

The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements should be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL PREPAID ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. (Royal 8vo.)

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1891 Edition, published on the 23rd February, 1891, consists of 900 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries at home and abroad may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with well-written Biographical Notices of leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1891 should be ordered at once. Price 5s., post free 5s. 9d. Abroad postage extra. Prospectuses free.

ELECTRICAL BOOKS AND PUBLICATIONS

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are agents for all the leading publishing houses at home and abroad*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. Vol. I. Price 7s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Vol. I. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

Several Further Volumes in Active Preparation.

NOW READY, IN TWO VOLUMES.

"THE ELECTRICIAN" PRIMERS.

Fully Illustrated.

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

SPECIAL NOTICE.

With this week's number of "THE ELECTRICIAN" we issue (gratis to Subscribers) a fine Steel-Plate Portrait of Professor von Helmholtz. Complaints of non-receipt should be promptly made to the Publisher.

SECONDARY BATTERIES.

Since the FAURE battery was introduced and described in a letter to *The Times* of May 16, 1881, as the marvellous "box of electricity," there has been ample time to gain experience of the commercial value of lead secondary batteries, and to form a judgment as to their prospects, and it is not without interest to recall the expectations aroused by it and see how far they have been realised. Sir WM. THOMSON, in his letter to *The Times*, dated Glasgow, June 6, 1881, hailed the advent of the FAURE battery as a solution of that most important problem, the conversion of electrical energy into a preservable and storable form, so that it could be used at any time when wanted. Referring to the long felt want of a battery which could have the chemical energy restored to its elements by being worked backwards by a steam-engine and dynamo, Sir WILLIAM says:—"But with all ordinary forms of voltaic battery the realisation of the idea seemed hopelessly distant. By PLANTÉ'S admirable discovery of the lead and lead peroxide voltaic battery, alluded to by your correspondent, an important advance towards the desired object was made 20 years ago; and now by M. FAURE'S improvement practical fruition is attained." This enthusiasm appears to have been generally shared, and with the invention of pasted plates the problem of the storage of electrical energy was taken as solved. Secondary batteries were to do for electric lighting "what a water cistern in the house does for an inconstant water supply," our tram cars and launches were to be driven by them, and the Herculean task of purifying the atmosphere on the Underground Railway was to be performed by using them, instead of steam engines, as a source of the motive power for the trains.

Ten years' experience cannot, however, be said to have realised the hopes then entertained. Although they are now largely used for electric lighting, no thoroughly satisfactory battery for traction purposes has yet been introduced, and we still have to submit to disinfection with sulphur, and to being blackened by soot, whenever we are compelled to travel on the Inner Circle. It is, therefore, important to discover whether the causes of the principal defects which have retarded the introduction of lead secondary batteries, *i.e.*, "buckling" and "sulphating," are such as can be remedied by improved

Digitized by Google

methods of manufacture, or whether they are traceable to the chemical reactions always occurring in normal working. Innumerable batteries have been brought out since the date of FAURE's great discovery, and much ingenuity has been displayed in effecting improvements in the mechanical structure of the plates, both of the PLANTÉ and FAURE type. Taking advantage of the experience gained in the manufacture of sulphuric acid that lead is much less attacked by the acid when containing antimony than when pure, the grids in the FAURE type of cell were alloyed with antimony, with the result of increased strength and durability. Many devices have also been resorted to to obtain and maintain good contact between the paste and the grid, with the result that considerable improvement has been effected in storage capacity. But, all these mechanical improvements notwithstanding, the various batteries have exhibited the characteristics observed by PLANTÉ in his cell. In all there is a rise of electromotive force on breaking the discharging circuit, with a corresponding fall on breaking the charging circuit; and a sudden lowering of the electromotive force at the end of discharge, not due to the exhaustion of the active material, since after a rest the battery will yield a further discharge. As sulphating and buckling also occur to a greater or less extent in all the batteries yet introduced, they would appear to be due, like the peculiarities in electromotive force, which PLANTÉ ascribed to the action of peroxides in the electrolyte, to chemical reactions common to the whole class of lead peroxide—sulphuric acid—lead cells, and not to any particular method of manufacturing the plates.

Turning to the work which has been done on the subject by physicists and chemists we find that in a Cantor lecture delivered in 1883, Prof. OLIVER LODGE pointed out that the sudden running down of the cell was not due to the exhaustion of the peroxide plate, as the cell would continue discharging if the lead plate was removed and a fresh one inserted. He also showed that the recovery of the electromotive force exhibited by the cell on rest is only to a very slight extent due to the peroxide plate. MIESLER has shown that, while the potential difference between the acid and the peroxide plate only exhibits a very slight falling off, even when the discharge is continued until the electromotive force of the cell has fallen to half its original value, that between the lead plate and the acid decreases very rapidly, and reverses at about 1·5 volts. This confirms Prof. OLIVER LODGE's observations, shows that the alteration in the electromotive force must be due to some change in the nature of the chemical compounds formed on the lead plate, or in the acid next it, and also shows that the changes occurring at the peroxide plate must be practically identical throughout the discharge. In reply to Dr. FRANKLAND's oxysulphate theory, Messrs. GLADSTONE and HIBBERT have shown that the formation of oxysulphates by the action of dilute acid on litharge and red lead respectively is very doubtful. However, since in the cell on starting the discharge we are dealing with the action of sulphuric acid on peroxide of lead and lead respectively, even if oxysulphates corresponding to the monoxide and sesquioxide of lead exist, it remains to be proved that these oxides are formed in the discharge of the cell before Dr. FRANKLAND's hypothesis of the action of the cell can be accepted. Mr. G. H. ROBERTSON has shown that the normal action of the cell gives rise to the formation of persulphuric acid in the first instance, and that this body forms hydrogen peroxide by secondary action, and, further, that the addition of hydrogen dioxide to the acid causes a lowering or reversal of the electromotive force in the case of a lead peroxide—lead couple. We are, therefore, in a position to account for the sudden lowering of the electro-motive force and also for the sulphating of the surface of the plates which takes place during rest, and which local action seems scarcely to explain. Although the knowledge of all the chemical actions involved in charge and discharge which we now possess does not enable us to suggest the addition of any substance to dilute sulphuric acid which shall permanently prevent the formation in it of deleterious bodies, and at the same time be harmless to the plates, we can now bring back to health damaged plates, and tell when the acid is getting into a bad state, and thus prevent injury to them.

For electric lighting, lead secondary batteries seem likely to fulfil the hopes entertained of them, particularly in connection with Central Station work. On the other hand we do not seem appreciably nearer a light and durable secondary battery for traction work. The great weight of a lead cell immediately places it at a disadvantage. Moreover, when we remember that in a fully charged cell, the peroxide paste is in such a finely divided and disintegrated state that it cannot be touched without removing some of the active material we can imagine what must be the speedy result of the constant wash produced by the movement of a car. We may prevent the formation of deleterious bodies in the acid as effectually as we like, but weight can only be diminished, and the injurious effects of wash can only be overcome by a radical alteration in the type of cell employed. It would seem, therefore, that we must look to some new departure, such as the alkaline copper cell, or Dr. PAUL SCHOOP's gelatinous electrolyte and not to a modification of the lead peroxide, sulphuric acid, lead cell for a completely satisfactory self-contained apparatus for the propulsion of tram cars.

HERMANN VON HELMHOLTZ.

Some thirty years ago the scientific visitor to Heidelberg could not fail to be interested in a large house, the "Riese," or giant, as it was termed, situated at the west end of the principal street of that town. The first floor of this house afforded shelter to the physiological, the second to the Physical Institute. In the upper story of this house Kirchoff and Bünsen compared the spectra of the metals with those of the sun; a few steps lower, Helmholtz built up the vowel sounds by combining the tones of vibrating tuning forks; Wilhelm Wundt, his then assistant, here taught us how graphically to record the contractions of the muscles, whilst the students, more inclined to play than to work, busied themselves with their prescribed practical exercises, which consisted in grinding teeth into slips of microscopic thinness.

When Helmholtz, our great master, walked through our work-rooms, and the quiet but penetrating glance of his large, mobile eyes fixed itself on our insignificant work, we listened with strained attention to his instruction. In general, his directions were expressed in few words, yet these were sufficient to cause us to work for days, both with our heads and our hands. For, besides attending to the ideal conception of a research, he did not in the least neglect the practical working details. I remember how, during many weeks, he made me build up a myograph out of the boards of a cigar-box, knitting needles, cork sealing-wax, and glass plates, and his great head nodded friendly approval at this 'prentice work of mine.

To-day that the whole world of learning celebrates his jubilee, and the German people, with just pride, congratulate their Helmholtz, and it appears becoming that we should cast a light over the path by which the great man reached his high position.

Hermann Ludwig Ferdinard von Helmholtz was born on August 31, 1821, at Potsdam, where his father occupied the position of a teacher in the "gymnasium." In his seventeenth year he entered the University of Berlin as a student. Helmholtz would have liked to have devoted himself to the study of

Digitized by Google

physics. Circumstances, however, compelled him to enter on the study of medicine, a course which was rendered easy for him by the liberal arrangements of the Frederick William Institute, an institution for the training of military surgeons. The education which he there received he has never regretted. In his speech "On Thought in Medicine," delivered at the commemoration of the foundation of the Institute for the Education of Military Surgeons in Berlin, on August 2, 1877, he esteemed "that to have been a real happiness which he at one time had felt to be burdensome." He expresses himself thus:—"Apart from the fact that I entered on the study of medicine at a period when anyone who was even moderately skilled in physical modes of examination found a fruitful virgin soil to cultivate, I consider the study of medicine to have been the school which taught me, as no other could have done, the eternal laws which are the bases of all scientific work." The high conception which he entertained of the aims and objects of medicine may be gathered from the following quotation:—"The proud saying of Hippocrates served almost as the watchword of the old deductive medicine 'ἰητρός φιλόσοφος ἰσόθεος' (godlike is the physician who is a philosopher)." If we conceive the philosophical physician of Hippocrates to be a man possessed of consummate insight into the causal relations of the processes of nature, we shall be able to say of such a man that he will indeed be able to render aid even as a god might do. So understood, the sentence of Hippocrates expresses, in three words, the ideal which our science has to strive after. Who shall say whether it will ever be attained?"

Medical education, at the time when Helmholtz, studied depended still essentially on the study of books; microscopes were still dear and rare. "I myself," relates Helmholtz, "succeeded in becoming possessed of one by falling ill of typhus fever during the autumn holidays of 1841, when, being as a pupil gratuitously treated in the Charité, I found myself, on my recovery, in possession of that part of my small income which had been accumulating during my illness. The instrument was not beautiful, yet by its aid I was able to recognise the nervous processes of the ganglion cells of invertebrates, which I described in my dissertation, as well as the vibrios referred to in my work on putrefaction and fermentation."

His inaugural thesis for the doctor's degree (November 11, 1842), the researches for which he undertook at the suggestion of the great Johannes Müller, afforded evidence of his intense power of observation, which always led him to discover the most important facts. This rare quality manifested itself likewise in the second work, already referred to, "On the Nature of Putrefaction and Fermentation" (1843). With all the strictness which the modern investigation of septic processes has been able to attain, did he demonstrate that putrefaction is not brought about, as Liebig had supposed, by the oxygen of the atmosphere, but that superheated air is entirely incapable of bringing about putrefaction or fermentation. In putrefying liquids he observed, with a magnifying power of 400 diameters, small spherules and large rod-shaped organisms, which moved slowly, and rotated around their long axes. Small pieces of boiled meat, enclosed in flasks, were likewise found by Helmholtz not to putrefy when he passed an electric current through the liquid, and, by the decomposition of water, set oxygen free. Schwann, his distinguished comrade in the laboratory of Johannes Müller, had already shown that vegetable cells bring about fermentations in solutions of sugar, which the introduction of superheated air was unable to induce. Helmholtz might, therefore, have considered his analogous observation as sufficient and complete in itself. But his scientific critical acumen, waging war against all sources of error, caused him to extend his observations. The extraordinary difficulties which these presented, at a time when many of our more valuable modern methods of investigation were not available, led to results which somewhat misled him. Surprised and doubtless disappointed by the conclusions to which his final experiments appeared to point, we find the youthful investigator (for he was still only 22 years of age) bowing modestly before the unwelcome truths of Nature, and formulating his conclusions as follows: "From these researches it appears that putrefaction may originate independently of vital processes." Thirty-nine years later he appended to the re-publication of this work ("Ges. Abhandl.," Vol. II., p. 737) the following remarks:—"Recent researches make it probable that organisms of very minute size (which the extraordinary magnifying power, modes of illumination, and methods of staining, of the present day, have for the first time allowed us to recognise) are able to pass through, or to grow through membranes.' At that time Helmholtz occupied the post of military surgeon in Potsdam. But he remained faithful to his scientific mission. He contributed to the "Advances in Physics" published by the Physical Society of Berlin. The invitation to write the article on "Heat" in the Encyclopœdic Dictionary of Medical Sciences gave him the opportunity (1845) of writing an essay on this subject, which, even to-day, may serve as a model. His thoughts turned in this Paper to one of the most important physiological questions relating to the nature of vital power: whether the life of organisms be due to a peculiar self-producing purposeful power, or is the result of forces acting also in inorganic nature. He examined the material exchanges of muscular action, and found that the substances contained in muscle soluble in water were diminished in quantity by muscular activity, whereas those extracted by alcohol were increased in amount, so that "a chemical change occurs in compounds contained in it." He expected at that time that a deeper comprehension of these processes would result from further investigations; and yet to-day the highly developed state of physiological chemistry is unable to give a clearer answer to the question. In near relation to this, he proved (1847) that muscles give out heat during activity.

In the same year, in a small pamphlet on "The Conservation of Energy," he gave a vigorous proof of the following proposition:—"In all cases of the motion of free material points under the influence of attracting and repelling forces whose intensity is solely dependent on the distance [the loss in potential energy is always equal to the gain in kinetic energy, and the gain in the former is equal to the loss of the latter, so that] the sum of the kinetic and potential energy is always constant." From this it follows that no energy is lost in the world, but that it alters only in its mode of manifestation, so that, for instance, chemical affinity can be converted into heat or electricity, this latter into heat or motion of masses, &c. At the same time, he showed that all the processes of Nature obey the laws of mechanics. Previously to this, heat had always been regarded as a "substance." Helmholtz showed "that the phenomena of heat can all be looked upon as motion." With this he brought science on to a plain path. But at first he met with opposition from authorities on the subject. His article was rejected by *Poggendorff's Annalen*, and amongst the members of the Berlin Academy only Jacobi, the mathematician, espoused his cause. Even when his fame penetrated through wide circles, doubt was thrown on the originality of this epoch-making work. Helmholtz had written his pamphlet in ignorance of the work of Robert Mayer (1842 and 1845). When still in the third form of the gymnasium of Potsdam, he had found it perplexing to reconcile the experiments of Rumford and Humphry Davy on the production of heat by friction with the then orthodox conception that heat was an imponderable substance. What wonder, then, that as a fully developed mathematician and physicist he should recognise that the "heat resulting from friction is to be looked upon as the apparently lost *vis viva*?"* Helmholtz readily acknowledged the priority of Joule and R. Mayer even before it was claimed, and was the first to bring into prominence the merits of the doctor of Heilbronn in the discovery of the great new universal principle.

But how far above his predecessors he was! R. Mayer's first essay gives no *proofs*, but only sets forth theses, and even in his more detailed article on "Organic Motion in its Relation to Metabolism" (1845) he supports only by general, although extremely ingenious, arguments his axiom that "in all physical and chemical processes the given energy remains a constant magnitude" (p. 32), and further, "in vital processes there is only a transformation of matter as well as energy, but never any creation of either the one or the other" (p. 40). Mayer, too, on even the most suitable occasions, does not mention his immediate predecessor Joule. In how different manner do the trained

* Lectures and Speeches. Vol. I., p. 66.

Digitized by Google

physicist and speculative doctor treat the same subject! Helmholtz proved experimentally the increased consumption and increase of heat during muscular activity. Mayer affirmed —without proofs—that every casual movement took place with the formation of carbonic acid and water; that "every muscle whose supply of atmospheric air is cut off ceases from its activity" * (p. 87). "With every muscular action, heat *in statu nascente* is set free" (p. 94). "In continued work there is a summation of this loss of heat which can be detected by observation" (p. 95). "A clever smith can bring a cold piece of iron to red heat by hammering; but this temperature is made at the expense of the temperature of his arm. *Ex nihilo nihil fit*" (p. 96).

Helmholtz calmly followed his own lofty path, as teacher of Anatomy in the Academy of Art in Berlin, and assistant in the anatomical museum; he succeeded one of his friends occupied in the same pursuits, namely, Brücke, and found another, E. du Bois Reymond, still with his teacher, Johannes Müller. In the following year, Helmholtz was called to Königsberg as Professor of Physiology and General Pathology. "General Pathology was looked upon by the ancients as the finest flower of medical science. But what formerly made up its contents has only historical interest for the disciple of modern science." It was on dogmas that the fundamental views of medicine were then based. Helmholtz was always an enemy of the deductive method. "The fact of a conclusion being drawn by the most accurate and logical methods from an uncertain premiss does not add a hair's breadth to its certainty or value." Many old physiologists considered it beneath their dignity to make experiments, but Helmholtz always maintained, in contradiction to the metaphysicians, that "it is the duty of scientific research to seek the laws governing disconnected facts." How fruitful were his methods is shown by his researches at Königsberg, in in the first of which, in 1850, he determined the duration of muscular contraction and the rate of transmission of nervous impulses.

(To be concluded.)

REVIEWS.

Der Betrieb und die Schaltungen der Elektrischen Telegraphen. 3 vols. By Dr. KARL EDUARD ZETZSCHE. (Halle a-S: Wilhelm Knapp.)

The present volume, "The Working and Connecting of Electric Telegraphs" is supplementary to the Doctor's well-known "Handbook of Electric Telegraphy," &c., and is a carefully compiled and well-illustrated work, dealing with everything of note or interest appertaining to telegraphy. G. B. Prescott in his "Electricity and the Electric Telegraph (1881)," says, "special attention has been paid to the voluminous contribution of Germany, a nation whose electricians unquestionably occupy the foremost rank among discoverers and inventors, but whose labours, although lying at the foundation of many of the most brilliant achievements of modern telegraphy, have heretofore remained for the most part unknown to the English reader." Dr. Zetzsche, however, by no means confines himself to the achievements of his own countrymen, his book being both comprehensive and cosmopolitan. Dr. Zetzsche has proved himself a most careful compiler of information relating to the different systems and instruments in use for land line and submarine telegraphy. The letter-press is clear and the illustrations numerous.

The first part of Vol. I. deals with keys and instruments; the second part with the use of these, and the circuits and connections for simplex and duplex working, electrical disturbances in cables, &c. In Vols. II. and III. the systems and connections for simplex telegraphy are further explained and illustrated, as well as those for "duplex" on short lines, long aerial lines, and for cables. Explanations are also given of the duplex, quadruplex, and multiplex. Towards the end of the last volume the author makes some judicious observations on the proper mode of training and the requisites of good telegraphists. Dr. Zetzsche's latest work is certain to attain the same popularity that his previous efforts have met with in Germany and elsewhere.

* Johannes Müller confirmed (1833-1837) already, in the older editions of his celebrated text-book, the observations of Spallaazani, that cold-blooded animals continue to expire carbonic acid even in an atmosphere free from oxygen. Burdach says the same of warm-blooded animals in his "Physiology" (1835), Vol. V., p. 375.

ELECTROMAGNETIC THEORY.—XIV.

BY OLIVER HEAVISIDE.

(Continued from page 354).

§ 77. To further exemplify the significance of the electric stress, let us introduce a foreign body into a stationary electric field. The field will be disturbed by its introduction, and will settle down to a new state; the change depending upon the nature of the foreign body, whether conducting or non-conducting, in substance or superficially, and upon whether it has a charge itself, or contains any other source of displacement. If it be a good conductor, either charged or uncharged, the final state, reached very quickly, will be such that the displacement will terminate normally upon its surface, thus reproducing the previous case (§§ 74 to 76). But if it be a non-conductor, the result is somewhat different. If superficially conducting, we may indeed have an ultimate electrification of the surface, so as to come wholly or partly under the same case: but if there be no superficial or internal conduction, or only so little that a long time must elapse for it to become fully effective, what we do is simply to replace the dielectric air in a certain region by another dielectric of different permittivity, usually greater. Then, supposing the external field to be due to charges upon insulated conductors or to internal electrification in the air (kept at rest for the purposes of the argument), no change will occur in their amounts; but there will be merely an alteration in the distribution of the electrification on the conductors, caused by the displacement becoming denser within the foreign body than before (or less dense, if its permittivity can be less than that of the air). The intrinsic electrification of the body itself, if any, must also be allowed for; but should it have none previously, it will remain unelectrified when introduced into the field, and the displacement will pass freely through it, and out again in a solenoidal manner. This is expressed by the surface condition

$$\mathbf{D}_1\mathbf{N}_1 + \mathbf{D}_2\mathbf{N}_2 = 0,$$

where $\mathbf{D}_1$ and $\mathbf{D}_2$ are the displacements in the air and foreign body respectively at their interface, and $\mathbf{N}_1$, $\mathbf{N}_2$ are the unit normals from the interface to the two media.

The only quite simple case (excepting that of infinite plane sheets) is that of a sphere of uniform permittivity brought into a previously uniform field. The ultimate displacement in the sphere is then parallel to the original displacement in the air. It may vary between zero and three times the original displacement, as the permittivity of the sphere varies from zero up to infinity. It is certainly a little surprising that the ultimate displacement with infinite permittivity should be only three times the original (and it is not much less when the permittivity is only 10 times that of the air); whilst, on the other hand, the zero displacement when the permittivity is zero (a quite ideal case) is obvious enough, because the displacement never enters the sphere at all, but goes round it. The original uniform field may be conveniently that between the parallel plates of a very large air condenser. There is, however, a double action taking place. When the transverse voltage of the condenser is maintained constant by connection with a suitable source, the insertion of the foreign body will increase or reduce the permittance of the condenser, and so increase or reduce its charge under the action of the constant source, besides concentrating the displacement within itself, or the reverse. With constant charges, however, when the plates are insulated, the insertion of the foreign body will reduce the transverse voltage when its permittivity exceeds that of the air; and conversely. Increase of permittivity also increases the stored energy when the transverse voltage is constant, but reduces it when the charges are constant.

Digitized by Google

Now, since the electric force does not terminate on the boundary of the foreign body, but extends all through it, so does the electric stress. So far, however, as the resultant force and torque on the body, when solid, is concerned, we may ignore the internal stress altogether, aad consider only the external, or stress in the air. This is a particular case of a somewhat important and wide property in abstract dynamics, which we may state separately thus.

§ 78. The resultant force and torque due to any stress in any region is zero. Or, any stress in any region forms a self-equilibrating system.

Imagine any distribution of stress to exist in a region A, and to terminate abruptly on its boundary. Or, equivalently, imagine a piece of a stressed solid to be removed from its place without altering the stress. The stress-variation, when estimated in a certain way, constitutes mechanical force tending to move the body. This will be in the case of an ordinary irrotational stress, entirely translational force. But there are two kinds. First, there is internal force, reckoned per unit volume, due to the continuous variation of the stress in the body. Next, there is superficial force, reckoned per unit area, due to the abrupt cessation of the stress. This surface traction is represented simply by the stress vector itself, acting on the inner side of the surface of the body. Now, the resultant effect of these two forcives, over the surface and throughout the volume of the solid respectively, in tending to translate and rotate it, is zero. Or, in other words, the force and torque equivalent to the surface forcive are the negatives of those due to the internal forcive. If it were otherwise, the differential action would cause indefinite increase in the translational and rotational energy to arise out of the internal mutual forces only of a body.

If the stress be of the rotational type, there will be an internal torque (per unit volume) as well as a translational force. Still, however, the resultant force and torque due to the surface tractions will cancel those due to the internal forces and torques.

In case there be any difficulty in conceiving the traction exerted on the surface of a body by the stress within itself, we may replace the sudden cessation of the stress by a gradual cessation through a thin skin. The solid is then under the influence of continuous bodily force only (and torque also, if the stress be rotational) conveniently divisible into the internal force all over, and the force in the skin. Otherwise it is the same.

Now put the solid piece back into its place again. Since its own stress balances itself, we see that whatever the forcive on the piece may be it must be statically equivalent to the action upon its boundary of the external stress only, constituting an external surface traction. There need be no connection between the external and the internal stress. The latter may be anything we like, so far as the resultant force and torque on the piece are concerned. The difference will arise in the strains produced, or in the relative internal motions, when for one stress another is substituted.

§ 79. Returning to the electric field, we see that whatever be the nature of the reaction of the foreign body on the original state of the field, the resultant mechanical action on the body as a whole is fully represented by the stress in the air just outside it, in its actual state, as modified by the presence of the body, and that we need not concern ourselves with the internal state of stress. Nor are we limited, in this respect, by any assumed proportionality of electric force to displacement in the body, or assumed absence of absorption, or other irregularities and complications. That is, we need not have any theory to explicitly account for the change made in the electric field by the body. Nor do we gain any information regarding the internal stress from merely a knowledge of the external stress, although that involves the reaction of the body on the electric field. This is the meaning of the statical indeterminations of the stress before referred to, and the principle applies generally.

The air stress vector **P** will usually have both a normal and a tangential component at the surface of a body, viz.:—

$$\begin{aligned} &\mathrm{U}\cos 2\theta \quad \text{normal,}\\ &\mathrm{U}\sin 2\theta \quad \text{tangential,}\end{aligned}$$

if θ be the angle between the normal **N** to the surface (drawn from the body to the air) and the electric force **E**, and U the density of the electric energy, or the tensor of the stress vector.

In only one case, however, will this external surface traction represent the real forcive in detail (as well as in the lump), viz, when there is no stress at all on the other side of the boundary, that is, in the case of a conductor in static equilibrium. In general, the real surface force is represented by the vector $\mathbf{P}_1 - \mathbf{P}_2$, the stress difference at the boundary, $\mathbf{P}_1$ being the external and $\mathbf{P}_2$ the internal stress vector, which two stresses may, if we please, be imagined to be united continuously by a gradually changing intermediate stress existing in a thin skin, an idea appropriate to molecular theories. (It may be remembered that **P** when positive means a pull.) Each of these may be split into a normal and a tangential component. Now, the tangential components are

$$\mathrm{U}_1 \sin 2\theta_1 \text{ and } \mathrm{U}_2 \sin 2\theta_2,$$

where the suffix $_1$ relates to the air, and $_2$ to the other medium.

Or $$\mathrm{E}_1\mathrm{D}_1 \sin\theta_1\cos\theta_1 \text{ and } \mathrm{E}_2\mathrm{D}_2 \sin\theta_2\cos\theta_2.$$

But here we have normal continuity of the flux **D**, and tangential continuity of the force **E**; (otherwise the surface would be electrified and covered with a magnetic current sheet); that is

$$\left.\begin{aligned} \mathrm{D}_1\cos\theta_1 &= \mathrm{D}_2\cos\theta_2,\\ \text{and}\quad \mathrm{E}_1\sin\theta_1 &= \mathrm{E}_2\sin\theta_2,\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (5)$$

These relations make the tangential tractions equal and opposite, so that there is no resultant tangential traction, and the actual traction is entirely normal, being the difference of the normal components of $\mathbf{P}_1$ and $\mathbf{P}_2$, or,

$$\mathrm{U}_1\cos 2\theta_1 - \mathrm{U}_2\cos 2\theta_2, \quad . \quad . \quad . \quad . \quad (6)$$

which is the same as (being subject to (5),

$$\begin{aligned} &\tfrac{1}{2}\,\mathrm{D}_1\cos\theta_1\,(\mathrm{E}_1\cos\theta_1 - \mathrm{E}_2\cos\theta_2)\\ &-\tfrac{1}{2}\,\mathrm{E}_1\sin\theta_1\,(\mathrm{D}_1\sin\theta_1 - \mathrm{D}_2\sin\theta_2) \quad . \quad . \quad . \quad (7)\end{aligned}$$

The coefficient $\frac{1}{2}$ comes in for a similar reason to before, § 75.

This formula (6) or (7) being the real surface traction when **E** varies as **D** in the body, and the stress is of the same type as in air, furnishes a second way of calculating the resultant force and torque on the body, when its permittivity is uniform; and it is noteworthy that the surface traction is, as in the case of an electrified conductor in equilibrium, entirely normal, although it may now be either a pull or a push.

§ 80. Noting that the mechanical force on the elastically electrizable body is situated where the change of permittivity occurs, and is in the direction of this change, it may be inferred that when the permittivity varies continuously there is a bodily translational force due to the stress variation which is in the direction of the most rapid change of permittivity. This is, in fact, what the stress vector indicates when c varies continuously, viz., the force represented by

$$-\tfrac{1}{2}\mathrm{E}^2\nabla c = -\nabla_c \mathrm{U}, \quad . \quad . \quad . \quad . \quad . \quad (8)$$

where ∇c means the vector rate of fastest increase of c roundabout the point considered. Since $\mathrm{U} = \frac{1}{2}c\mathrm{E}^2$, the second form in (8) will be understood, meaning the vector slope of U as dependent upon the variation of c only.

This bodily force, and the previous surface force may be harmonised by letting c vary not abruptly, but continuously from the value c_1 on one side to c_2 on the other side of the surface of discontinuity, through a thin skin, and summing up the translational forces in the skin by the formula (8). Thus, if x be measured normal to the skin, the translational force per unit volume is $-\frac{1}{2}\mathrm{E}^2\,(dc/dx)$ in the direction of the normal; or

$$\begin{aligned} &-\tfrac{1}{2}\,\mathrm{E}_n^2\frac{dc}{dx} - \tfrac{1}{2}\,\mathrm{E}_t^2\frac{dc}{dx}\\ &= -\tfrac{1}{2}\,\mathrm{D}_n^2\,\frac{1}{c^2}\,\frac{dc}{dx} - \tfrac{1}{2}\,\mathrm{E}_t^2\frac{dc}{dx}, \quad . \quad . \quad . \quad (9)\end{aligned}$$

where E_n and D_n are the normal components of **E** and **D**, and E_t the tangential component of **E**. Now D_n and E_t are constant ultimately, for the reason before given, so we can integrate (9) with respect to x immediately, giving

$$\left[\tfrac{1}{2}\frac{\mathrm{D}_n^2}{c} - \tfrac{1}{2}c\mathrm{E}_t^2\right] = \left[\tfrac{1}{2}\,c\mathrm{E}_n^2 - \tfrac{1}{2}\,c\mathrm{E}_t^2\right] \quad . \quad . \quad (10)$$

Digitized by Google

between the limits; or, since E_n and E_t are proportional to the cosine and the sine of θ respectively.

$$[\tfrac{1}{2} cE^2 \cos 2\theta]$$

between the limits, which is the same as (6), which was to be verified.

§ 81. Since a sphere of uniform permittivity placed in a uniform field causes the external lines of electric force to be symmetrically distorted fore and aft, it has no tendency to move, but is merely strained. But if the body be not in an initially uniform field, or be not spherical, complex calculations are usually needed to determine the effect. If, however, it be only a small piece, the tendency is for it to move in the direction in which the energy, or the stress, in the field increases most rapidly, independent of the direction of the electric force, when its permittivity exceeds that of the gaseous medium. The total electric energy will be diminished by permitting the motion when the charges are constant; but increased should the field be kept up by constant sources of voltage.

These properties are rendered particularly evident by taking the extreme cases of infinite and zero permittivity of a small body placed in a widely varying field, that surrounding a charged sphere, for example, the electric force varying in intensity as the inverse square of the distance from its centre. Here the non-permittive body is repelled, for the lines of force go round it, and the lateral pressure comes fully into play, and is greater on the side next the charged sphere. On the other hand, with the infinitely permittive body, concentrating the displacement, it is the tension that comes fully into play, and this being greater on the side next the charged sphere, the result is an attraction. The permittance of the sphere, also, is increased in the latter case, and decreased in the former—that is, when the natural motion of the body to or from the sphere is allowed; so, since the total electric energy is $\frac{1}{2} SV^2$ where S is the permittance and V the voltage, or, equivalently, $\frac{1}{2} VQ$, if Q is the charge, we have always a diminution of energy when the natural motion is allowed, whether resulting from attraction or repulsion, if the charge is constant; but an increase of energy if the voltage is constant.

In intermediate cases the tension is dominant when the c of the body exceeds, and the pressure is dominant when it is less than that of the air, there being perfect equilibrium of a piece of any shape in any field if there be equality of permittivity, and therefore no disturbance of the field. Here we see the part played by the lateral pressure in the case of conductors in equilibrium. It has no influence on them immediately, and might be thought wholly unnecessary, but it is equally important with the tension in the non-conducting dielectric itself.

§ 82. Passing now to the corresponding magnetic side of the stress question, we may observe that the analogy is an imperfect one. Thus, proceeding as at the beginning of § 74, to have a stationary magnetic field without impressed forces, we shall find that there must first be no magnetic conduction current; and next, that the gaussage in any circuit must be zero. The magnetic force we then conclude to be confined entirely to the magnetically non-conducting regions, and to terminate perpendicularly upon their boundaries. Then we come to the conception of a number of detached magnetic conductors immersed in a magnetically non-conductive medium, these conductors having magnetic charges on them measured by the amount of induction leaving or terminating upon them, with possible associated volume magnetification in the non-conducting medium.

The magnetic stress will exert a normal traction

$$\mathbf{NT} = \tfrac{1}{2}\mu \mathrm{H}^2 \mathbf{N} \quad . \quad . \quad . \quad . \quad . \quad (12)$$

per unit area on the conductors, and a force

$$\mathbf{H}\sigma = \mathbf{H} \operatorname{div} \mathbf{B} \quad . \quad . \quad . \quad . \quad . \quad (13)$$

per unit volume on tridimensional magnetification, of density σ, measured by the divergence of the induction. These are analogous to the forces on surface and volume electrification.

Also, when the inductivity μ varies, we shall have a normal surface traction of amount,

$$T_1 \cos 2\theta_1 - T_2 \cos 2\theta_2 \quad . \quad . \quad . \quad . \quad (14)$$

per unit area, analogous to (6), when μ changes value abruptly at the interface of two media; and a force

$$-\tfrac{1}{2}\mathrm{H}^2 \nabla\mu \quad . \quad . \quad . \quad . \quad . \quad . \quad (15)$$

per unit volume, when μ varies continuously.

The forces (12), (13), however, are absent, because of the absence of magnetic conductivity, and, in connection therewith, the absence of "magnetification." But (12) may be sometimes used, nevertheless, when it is the stress across any surface that is in question, and we create surface magnetification by regarding one side only.

We are, therefore, left with the forces (14), (15), depending upon variation of inductivity, abrupt or gradual. These explain the mechanical action upon elastically magnetised media, *e.g.*, the motions of bodies to or from a magnet pole, according as they are paramagnetic or diamagnetic, which, it should be remembered, depends fundamentally upon the variation in the intensity of magnetic force near the pole; and the axial equilibrium of a paramagnetic bar, and equatorial equilibrium of a diamagnetic bar. Faraday's remarkable sagacity led him to the essence of the explanation of these and other allied phenomena, as was later mathematically demonstrated by Sir W. Thomson. Questions relating to diamagnetic polarity are, in comparison, mere trifling.

(To be continued.)

THE FRANKFORT EXHIBITION.—VII.

(FROM OUR SPECIAL CORRESPONDENT.)

In a side division of the Hall for the Distribution of Electricity, the Allgemeine Electricitäts Gesellschaft have set up a small model plant on the so-called rotary current system. As

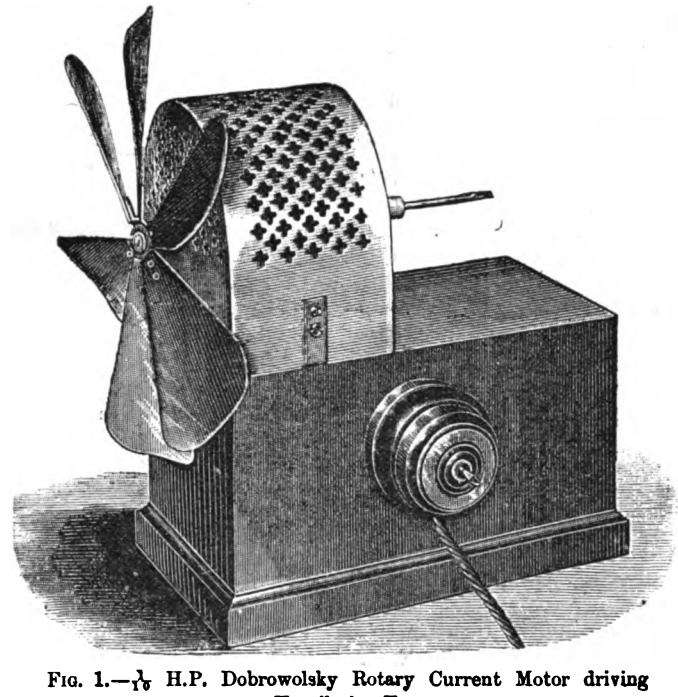

FIG. 1.—$\frac{1}{10}$ H.P. Dobrowolsky Rotary Current Motor driving Ventilating Fan.

the principle of the system has been recently fully explained in *The Electrician* (August 7th), I need not enlarge upon it here. The model plant comprises two motors, the first being a $\frac{1}{10}$ H.P. motor, driving a ventilating fan (Fig. 1). The second motor (Fig. 2), is of 2 H.P., but will take a load of 4 H.P. without perceptibly slowing down. It runs normally at about 1,800 revolutions. The current driving these two motors is supplied from a machine which is driven by continuous current supplied from an Oerlikon dynamo in the Machine Hall. Directly coupled to the 4 H.P. motor is a continuous current dynamo, running a number of glow lamps arranged in multiple arc. The motor is wound for 70 volts, with 30 Ω. It starts at full load

Digitized by Google

and, like the others, it has the advantage over ordinary alternating motors that it is not suddenly stopped when over-loaded; Its commercial efficiency when running at normal load is said to be as high as 82 per cent.

The Schuckert dynamo is almost as well known in England as in Germany, where it has gained a great reputation by reason of its good workmanship and solidity of construction Since its first introduction the Schuckert type has naturally been considerably modified, and the machines shown at Frankfort contain all the numerous improvements suggested by long experience. The field-magnets are now made shorter and of larger cross-section, and the machines have as few parts as possible; the bearings are large, and the armatures carefully balanced. In Fig. 3 is shown the largest dynamo exhibited. It is a shunt machine coupled direct to a 320 H.P. steam engine by Kuhn, of Stuttgart-Berg, running at 160 revolutions. On each side of the Gramme ring armature are 14 pole pieces. The iron forming these 28 poles is cast in four parts, which are bolted together, and enclose the whole machine, openings round the

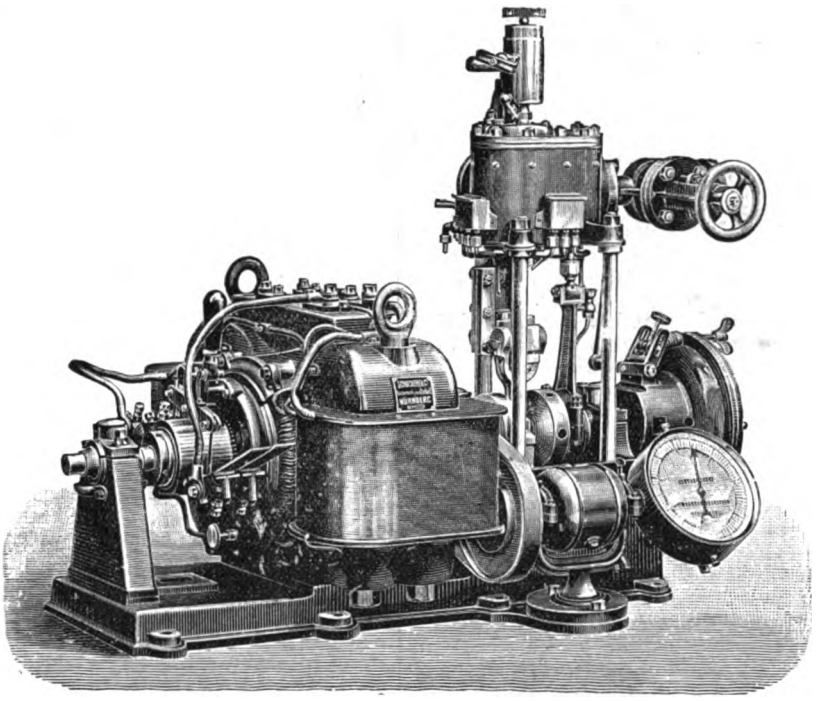

Fig. 4.—Schuckert Ship-Lighting Plant.

casing giving sufficient ventilation for the armature. When it is necessary to examine or repair the armature the top half of the frame is unbolted from the lower, and simply raised up above, leaving the armature bare. The cast-iron frame is bolted to the bed-plate of the machine, from which rise the supports for the armature bearings. These supports are forked round the bearings and prolonged above them, where they meet horizontal pieces from the frame to which they are bolted. The armature is made of laminæ of the very best soft Swedish iron.

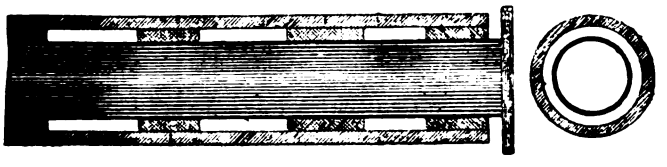

Fig. 5.—Emmerling System of Steam Pipe Lagging.

The diameter of the armature is 7ft. 10½in., and that of the 560 part commutator 4ft. 11in. The output at full load is 1,000 amperes and 230 volts. The weight of the machine is about 22 tons. Two other smaller machines of the same type are also shown by Schuckert and Co. One of these is of 200 H.P., and has been specially built for transmission of power purposes. The 200 H.P. machine weighs about 18 tons. Large machines of the same make as the dynamo first described, and of 350 kilowatts each, have been supplied to the Hanover Electricity Works (15,000 glow lamps), Altona (15,000 glow lamps), and Düsseldorf (20,000 glow lamps). In Fig. 4 is shown a small ship lighting plant designed by this firm, the steam engine being by Daevel, of Kiel.

Among the many different systems of steam pipe lagging to be seen at the Exhibition, that of Emmerling, of Nuremberg, seems worthy of notice. The material is composed of a mixture of cork and tar, and is subjected to great pressure and high temperature in the course of manufacture. The substance is arranged in such a way as to leave air spaces at intervals along the pipe to be covered, in the manner shown in the accompanying sketch (Fig. 5). The cork and tar mixture is put on in two portions. The outer portion runs in a continuous strip along the whole length of the pipe, and the inner portion is put on in rings at short intervals. The outer covering is in 20in. lengths, and the joints are always made at the middle of one of the interior rings, which are each about 2in. broad. The air space left in every 20in. of pipe length amounts to 16in. The thickness of the inner rings is 1in. The air thus confined in the spaces all along the pipe gradually takes the temperature of the steam pipe, and, since it is stagnant, it forms an admirable non-conductor. The lagging material, moreover, does not absorb moisture, and is unaffected by variations of temperature. The material is largely used in the Exhibition.

NOTE ON SOME LATELY MANUFACTURED TELEPHONE CABLES.*

BY FREDERIC A. C. PERRINE.

We are constantly using the telephone over both long and short circuits, and it is largely from the telephone "expert" that the modern electrical engineer was developed; yet to-day there is no department in electrical engineering concerning which accurate knowledge is so little diffused and difficult to obtain as that of the details of a telephone exchange, the requirements of the instruments, the switchboard, and the line. The electrical measurements of the lately-opened London and Paris telephone line were published in all the journals, and a report of the tests with the different instruments; but to a majority of our electricians these data afforded little basis for comparison.

In England to-day, and within a few years, in this country, a well-insulated line meant invariably one in which the wire is covered either with rubber or gutta-percha, and, except in long submarine

* From the *Electrical World* of New York.

Digitized by Google

cables, little attention was paid to the retardation due to capacity. Accordingly, on the introduction of the telephone, by reason of the multiplication of wires, and the consequent demand for underground circuits, cables were made and laid of rubber and gutta-percha-covered wire. In spite of every precaution it has been found impossible to keep the gutta-percha from oxidising unless laid under water and in the dark. The rubber cables have stood better, but in these, as they were originally made, two defects have developed, and one has proved insurmountable. In the first place, on account of the parallel laying of the conductors, in spite of the highest insulation, it was possible to talk from one wire to another by static induction. This defect was readily overcome by using an entirely metallic circuit, and twisting together the two wires composing it into pairs, but the second defect has been found to be one inherent in the use of any solid insulation, such as a gum-like gutta-percha or rubber. On account of the high specific inductive capacity of these materials, it is found that a retardation of the electrical waves is produced which soon muffles and finally effaces entirely all articulate speech.

Investigating this phenomenon, Prof. Jacques, of Boston, has found that for a Blake transmitter the limit of speaking is reached when the product of the resistance by the capacity of the line reaches 2,000, and for the long distance or Hunnings transmitter the limit is reached when this product becomes 4,500. Of course beyond these limits experts can do some talking, and Mr. W. H. Preece places the latter figure at 6,000. But the figures of 2,000 and 4,500 represent more nearly the limits in every-day practice.

In the case of any telephone cable, therefore, the requirements are a low-conductor resistance, and at the same time the lowest static inductive capacity. These requirements are necessarily limited by the mechanical construction due to the size of the ducts available and the cost of manufacture. In all of our cities subways have been laid having ducts from 2in. to 3in. in diameter, and, in consequence, cables must be made of diameters not exceeding 2⅝in., and, indeed, it is preferable that a diameter of 2¼in. be not exceeded for a 3in. duct, or 2½in. for a 2½in. duct., on account of the necessary internal irregularities of the iron pipe.

Now, taking these external dimensions, it has been found that if the conductors be insulated each to one-eighth of an inch, then in the 2¼in. cable 60 pairs can be nicely laid, allowing one-eighth of an inch for the thickness of the lead, and in the 2½in. cable it is possible to lay 83 pairs, allowing in each of these one extra pair for possible defects in manufacturing or laying. These cables have been adopted as the standard in size and insulation, and the next question to be settled has been the size of the conductor.

No consideration of heating is here necessary, and the loss of potential on account of the resistance is also a small factor in comparison to the retardation from the high capacity. The use of the finest sizes of wire has been found inadvisable on account of the difficulty of manipulation in manufacturing and splicing in the manholes. No. 18 B. and S. gauge soft copper wire, with a maximum resistance of 36 ohms per mile, was accordingly adopted, and has been the standard for several years. By reason of the rapid extension of the telephone exchanges in cities, and the consequent small importance of the resistance of the cables, the size has been reduced, at the last Telephone Conference, one gauge, and now stands at No. 19 B. and S. with a maximum resistance of 46 ohms per mile.

With the external diameter; the diameter of the insulation and the diameter of the conductor all fixed, the problem presents itself that the insulating material be used which will secure the lowest capacity, and hence the best circuit for talking. Dense gums, such as rubber and gutta-percha, as we have said before, give, with the cable indicated, a capacity of ·3 microfarads per mile, or the equivalent of 110 miles of pole line, composed of No. 12 B. and S. hard drawn copper wire, strung 36ft. in the air. Besides, both the great cost and unreliability of these materials render their use undesirable. The first advance that was made was the use of cotton artificially dried and saturated with paraffin. By this means, capacities from ·2 to ·18 have been obtained, and this, with the cotton and resin oiled cable led the Telephone Conference to reduce their specifications to ·18 demanded, or the equivalent of about 67 miles of pole line. The next step in advance was the use of dry cotton without any saturation whatever. Here a capacity as low as ·1 to ·11 was obtained, and the pole line length of a mile of cable reduced to 37. At about this time we commenced a series of experiments at the Roeblings', with a view of determining any possible lowering of this capacity still further, and as a result we have succeeded in making and laying two cables, one in Boston and one in New York, of No. 18 B. and S. wire, of which the capacities after laying are measured as ·082 and ·081 respectively, with a wire resistance of 33·6 ohms per mile, or, in the case of the New York cable, a retardation equivalent to 28 miles of pole line. With the smaller sized wire lately specified this retardation should be reduced at least 5 per cent. By reason of these high results, the last conference reduced its specifications to an average capacity of ·085 with a maximum of ·09.

With a cable such as we have laid in New York, the conductor resistance being about 33·6 ohms and the capacity ·081, the product of the resistance by the capacity is 2·7216 per mile, and through such a cable one could talk about 736 miles with a Blake transmitter, or about 1,650 miles with a Hunnings. This represents not only the best results obtainable in fair weather under the best conditions, as is the case with a pole line, but the every-day practice, whatever the weather. This consideration, together with the total absence of cross-talk, for which these cables are rigorously tested with a breaking induction coil, render the cable of to-day no longer a bugbear, but a comfort to both the manager of the telephone exchange and its subscribers.

THE FIELD TELEPHONE.*

In the usual forms of receiving telephones it has been the practice to polarise the core and diaphragm to the utmost possible extent. A novel form of telephone has, however, been recently devised by Mr. Stephen D. Field, of Stockbridge, Mass., which is both a receiver and transmitter, and in which the inventor proceeds in a directly opposite manner, aiming to have these parts as neutral as possible, though at the same time making use of a magnet of great strength.

This instrument, shown in the accompanying illustration (Fig. 1), is of the polarised type, in which the permanent magnet constitutes a practically closed magnetic circuit, and has an open electro-magnetic circuit in which the diaphragm is situated. These two magnetic circuits are so arranged relatively to each other that the currents flowing around the poles of the open electro-magnetic circuit will cause more or fewer lines of force to be deflected from the closed or practically closed magnetic circuit, owing to the peculiar reactionary effect of the currents in the coils of the electro-magnets.

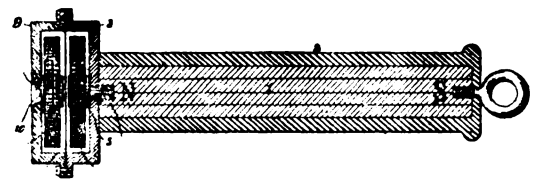

FIG. 1.—Field Telephone.

The action will be understood from the engraving, in which 1 represents a permanent magnet, made up of a number of separately magnetised steel bars. At the N-pole of this magnet is placed a cylindrical iron armature 3, attached to the magnet system by the core 5, whose projecting end is screwed into the magnet, and on which is mounted a helix, as shown. Across the face of the box armature is placed the diaphragm, which is held in position by the cover of the box. This cover carries on its inner face a projecting tubular core, on which is mounted another helix. The current flows in opposite directions in these two helices, as indicated by the arrows.

By this construction, two paths are opened for the lines of force from the magnet pole N; one by way of the walls of the case, with which the diaphragm is in direct contact, and the other by way of the cores 5 and 10. The latter path is broken by the space between these cores, and in this space the diaphragm vibrates. So far as concerns the cores, but very little polarity will normally be found between them in their adjacent ends, since the iron case forms a short circuit or "magnetic shunt" around them, and consequently the diaphragm will not be attracted toward one any more than toward the other by the mere influence of the permanent magnet.

Considering now that current-impulses are passing through the coils, the action will be as follows:—We will suppose that the current flows in the coil on the right of the diaphragm in such direction that it tends to induce S-polarity at the front end of core 5. Then a similar polarity will be developed in the front end of core 10. The lines of force will tend to circulate through the two magnetic circuits formed by the diaphragm and the sides of the iron box. Those lines due to the magnetisation of core 5 will tend to flow (*see* Fig. 2) from the end of the core through the box to the diaphragm, and through the diaphragm to and through the air-space between it and the core 5. These lines of force will be opposed in the air-space by the lines flowing through the air-space due to the permanent magnet, but the lines due to the other coil will proceed from the end of the core to the side of the box, to the diaphragm, to the air-space, and back to the end of the core. These lines will be assisted in the air-space by the lines from the permanent magnet, but will oppose the flow of the latter through the box, and the lines from both sources will pass in multiple arc through the diaphragm.

* From the *Electrical Engineer* of New York.

Digitized by Google

The lines of force due to the permanent magnet will, therefore, follow the path through the box to the diaphragm, through the diaphragm to core 10, and through core 10 to the south pole of the permanent magnet.

It will, therefore, be seen that one core will be strengthened and the other will be weakened by any given current-impulse which circulates through their surrounding coils, and the diaphragm will, of course, be attracted by the stronger polarity. The amount of

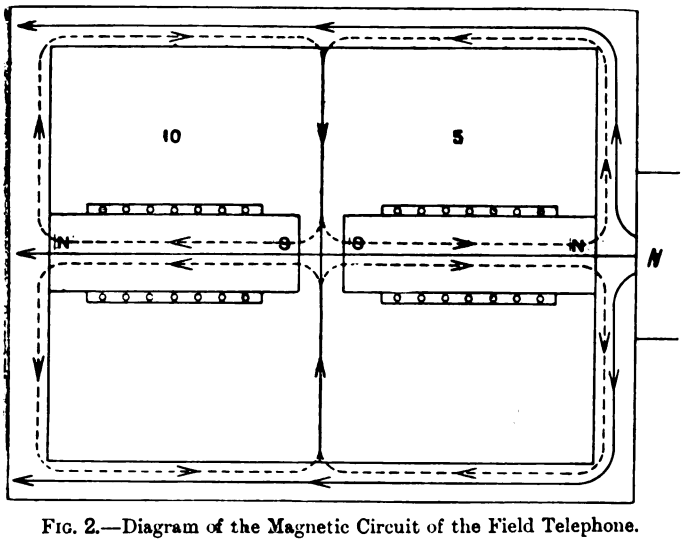

FIG. 2.—Diagram of the Magnetic Circuit of the Field Telephone.

this respective weakening and strengthening depends upon the current flowing. The result is a movement of the diaphragm toward one or other of the cores with a force dependent upon the strength of current used; and as the currents in the respective parallel coils flow in opposite directions, their inductive effects largely serve to neutralise their magnetic lag, so that the latter is quite unaffected by the strength of current flowing. In all cases the movement of the diaphragm is exceedingly sharp and prompt, whether the current used be very heavy or almost infinitely small.

THE ELECTRIC TRANSMISSION OF POWER.*

BY GISBERT KAPP.

LECTURE III.

(Continued from page 418.)

I have occupied some time in putting before you this transmission plant, because exact information about successful engineering work is of great value to practical men; and the Schaffhausen plant is certainly one of the best and most successful examples I could have chosen. The power transmitted is certainly large, according to our present ideas, but there is good reason to believe that—in point of magnitude, at any rate—this transmission will very soon be eclipsed by other work of this kind. There are projects afloat for utilising the power of the Rhine, near Bâle, to the tune of tens of thousands of horse-power, and at Niagara, as you all know, a total of 125,000 H.P., or a little over 3½ per cent. of the total power of Niagara, is to be taken from the Falls and transmitted to various distances, the longest distance being some 20 miles. I am not in a position to give you details of any of the schemes which have been submitted to the Niagara Commission, since these are the property of the Cataract Company, but, by the courtesy of several members of the Commission, notably Dr. Coleman Sellers, I am able to give you a general outline of the schemes. My object in applying to the Niagara Commission for information of this kind was to obtain some indication of the opinions which leading modern engineers entertain of electric power transmission, and to put the result of my inquiry before you. Lest the general condition of the Niagara scheme may not be quite familiar to all of you, I shall now throw upon the screen a picture of the Falls, and give you very briefly an outline of the objects for which the Cataract Company has been established.

Of the immense power represented by the descent of the river from its upper to its lower level over the Falls (about 3½ million H.P.), there is utilised at present an aggregate of only about 5,000 H.P. in the mills you see on the left of the picture. The water is brought to these mills by a surface canal from the upper reaches of the river, and, after passing through turbines, is discharged into the open air about half-way between the level of the ground and the level of the river below the tail races, forming a number of miniature waterfalls. Only about half the available head is therefore utilised. If the system adopted hitherto could be followed in future, there would be little difficulty in establishing a station for the generation of any amount of power in this locality, but there is a strong tide of public opinion against the establishment of any more hydraulic works on the river bank, to say nothing of the difficulty of finding room for them and the open-air canal which would be required. The Cataract Company have, therefore, resolved to carry out their operations, to a great extent, underground; and at the present moment are driving a tunnel 30ft. high by 20ft. wide, and about 6,700ft. long, which is to serve as a tail race for the water coming away from their power-station. This tunnel is shown on the picture by two dotted lines, and its mouth is partly submerged under the level of the lower river. The total fall between the upper and lower river is 200ft., and the net fall available for the turbines is 140ft. The fact that the tail race is a tunnel necessitates the turbines being placed at least 110ft. underground, since the suction tube of a turbine cannot be made longer than the column of water which can be balanced by atmospheric pressure, and this increases very materially the engineering difficulties of the work.

Last summer the Cataract Company invited a limited number of engineers to send in projects for the creation and transmission of power, and instituted a Commission, under the presidency of Sir William Thomson, to investigate and report on the projects. There were in all 20 competitors, but of these only 14 complied with the programme drawn up by the Commission, and were therefore held to be qualified to have their projects examined. Of these 14, eight competitors sent in combined projects for the creation and transmission of power, four referred only to the creation, and two only to the transmission of the power. The point of interest to us is what methods were suggested by the 10 qualified competitors in transmission. The question is somewhat complicated by the fact that some competitors have suggested mixed systems of transmission, and that, in classifying the schemes into electrical, pneumatic, and hydraulic, we must count some competitors twice over. On this basis I find that the following represents the transmission projects:—Electrical, 7; pneumatic, 6; hydraulic, 2. It is certainly remarkable that the balance in favour of electric transmission should be so small. And it is equally remarkable that there should have been as many as six competitors who either wholly or partially advocated pneumatic transmission. The experience of colliery managers goes to show that even over the comparatively short distances over which they use pneumatic transmission, the total efficiency lies generally between 20 and 30 per cent., and does certainly not exceed 40 per cent. We cannot suppose that engineers who have sent in pneumatic projects are ignorant of this fact, or, at any rate, we must suppose that the majority of them are quite aware that high efficiency cannot be expected from compressed air transmission. If, nevertheless, they have adopted compressed air in preference to electricity, it must be for one of two reasons. Either they have no confidence in the capabilities of electric transmission, or they consider the cost so high that the interest on the extra capital and the greater depreciation of the plant will more than counterbalance the advantage of high efficiency. It cannot be denied that, in the present state of our knowledge of electric transmission, there is some ground for both these views. The Niagara problem is unique, both in magnitude and distance, and I am bound to confess that we electrical engineers are at the present moment not quite prepared to face it. At the same time I must say that I feel convinced that in a few years from now there will be not one, but a dozen men ready to face this problem with a very good chance of successfully solving it. As a matter of fact, we are at present on the threshold of a new system of electric power transmission. The old system of using continuous currents and ordinary dynamos has been perfected to a point which leaves little to be desired, but it has its limits, and, unfortunately, the Niagara problem, or at least a part of it, is just a little beyond these limits. Hence we find that only about half of the competitors have had the courage to propose electric transmission. Of these, only two suggested the use of alternating currents at voltages of 5,000 and 10,000 respectively; the others followed the old lines of continuous current transmission at voltages varying between 1,600 and 4,500 volts.

This brings me to the consideration of a subject which is of great importance not only in regard to the Niagara problem but to long distance transmission generally, namely, the limits of distance up to which the usual system of transmission is practicable. If you will refer to the table giving the cost of transmission plants, given in my last lecture (*see ante* p. 710), you will find that, for large powers at any rate, an increase of distance up to four or five miles does not make the cost prohibitive, and you will conclude from these figures that, within a five mile limit, the whole system of electric

* Cantor Lectures delivered before the Society of Arts, February and March, 1891.

Digitized by Google

transmission is certainly feasible. How much farther you might go is a matter for theoretical consideration ; the table does not help you much, as the only example of a very long distance transmission is one where the power is small, and is, therefore, in a certain sense, misleading. I have given you a formula by which you can calculate the most economical voltage for any distance ; and if you do this for many cases, taking, for instance, 500 H.P. as your unit of power, you will find that as the distance increases beyond five miles, the economical voltage begins to grow beyond the limit which might be considered practicable for one machine. It is quite impossible to lay down hard and fast rules. Under certain conditions, especially if you have to transmit cheap water-power, you may possibly reach a distance of 10 miles before getting to the limit of voltage ; but, whatever may be the special conditions of the problem, there is a limit of distance beyond which a single machine will not reach. "Very well, then," you might say, "if a single machine cannot be made to give the required pressure, let us put two or three machines in series." To correctly appreciate such a suggestion, let us first of all see what limits the voltage of a machine. Two things limit it ; the commutator and the general insulation. Practical dynamo makers will tell you in large machines they are quite prepared to put 1,000 volts on the usual Pacinotti commutator—if necessary, they will go to 2,000 volts, but with some misgiving ; and if you ask them to make a machine for 3,000 volts, they will, as likely as not, refuse. I do not refer to the Thomson-Houston or Brush machines, which have special commutators, but to large machines giving an even current and a high efficiency, such as we require in the transmission of power. We may thus conclude that 2,000, or, at the outside, 3,000 volts, is the limit of voltage to be obtained from a single commutator. But the general insulation of the machine must also stand this pressure, and where, as in dynamos and motors, the insulation consists of cotton, paper, fibre, varnish, and like materials, which are subjected not only to electrical, but also to mechanical strains, 3,000 volts is quite high enough for safe working. The commutator difficulty can, of course, be got over by putting several machines in series and insulating their frames from earth. The difficulty of general insulation can, however, not be met so easily. This you

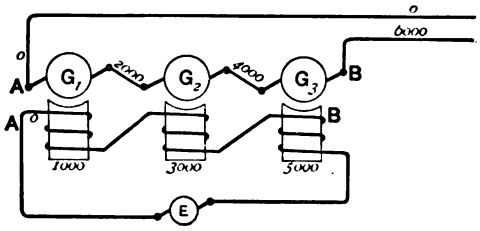

FIG. 7.

will see by referring to Fig. 7, which shows, diagramatically, three 2,000 volt machines placed in series. Shunt excitation at the high pressure of 2,000 volts is, of course, out of the question ; series excitation introduces complication and certain difficulties, especially at the motor station ; and separate excitation, although simple and easily worked, has the disadvantage of throwing great electrical strains upon the insulation between the exciting coils and the frames of the machines. Imagine, for instance, that there is a weak place at A, between the exciting coil and the frame of the first machine, then the strains between the exciting coil and the frame of the third machine at B, will be about 6,000 volts, even if all the machines are perfectly insulated from earth. With series self-exciting machines, the strain would, of course, be limited to 2,000 volts, but there still remains the difficulty that all the armatures would have to be mechanically connected by insulated couplings, and there would also be great danger in touching even the iron frame of any machine. You see the use of several machines in series is not such an easy matter as it may look at the first glance, and this method has, as far as I know, only been adopted in cases where the total voltage was under 2,000.

The net result of our investigation may be stated by saying that the electric transmission of power by continuous currents is economical and safe up to distances for which the most economical voltage does not exceed 2,000, or, at the outside, 3,000 volts, but that beyond these distances some other system must be applied. That this other system must also be electrical is evident, for we know perfectly well that distances beyond the reach of our present electric transmission systems are hopelessly beyond the reach of lines of shafting, flying ropes, air, or water. Now what is this new electrical system which shall enable us to carry power over ten or twenty, or perhaps a hundred miles ?

In attempting to answer this question I must perforce leave the safe ground of solid facts and engineering practice, and enter into the domain of speculation. Yet speculation based upon experimental results which in themselves are as reliable as were those experimental results which have led to the practical development of electric-power transmission as we know it now.

The starting point in the theory which I have now to bring before you is the well-known disc of Arago. If a copper disc be rapidly revolved under a compass needle, the latter is also set into rotation. I am able to show you this experiment, by the kindness of the Science and Art Department, who have lent me the apparatus you see before you. Between the copper disc and the compass needle is placed a sheet of glass so as to prevent air currents from affecting the needle. If I set the disc in motion you see that the magnet very soon follows. To make the motion of the latter better visible, coloured pieces of paper are attached to the poles. Now, the fact that the magnet revolves is evidently due to there acting upon it some mechanical force. The explanation is perfectly simple. The disc, in passing under the poles of the magnet, becomes the seat of a very complex system of electromotive forces, which produce an equally complex system of currents. Some of these currents cross the path of the lines of force emanating from the magnet, and thus mechanical forces are set up between the disc and the magnet, causing the latter to rotate. It is as though there existed between the disc and the magnet a kind of electro-magnetic friction by which the magnet is dragged after the disc. Since all motion is relative, it is perfectly clear that we might regard the magnet as revolving, and then the disc will be dragged after it. With the apparatus before you this experiment would not succeed, since the magnet is small and the disc is heavy ; but if we were to employ a very strong magnet, and revolve it rapidly enough, there would be no difficulty in setting the disc in rotation, and even obtaining power from it. I have said a moment ago that the system of currents set up in the disc is very complex, and you will easily see that only those currents which are more or less radial, and of these only their radial components, are instrumental in exerting mechanical force, whilst all the other currents represent simply so much waste power. To make an efficient machine we must, therefore, not employ a continuous disc, but a system of conductors, so arranged as to force the currents to flow as much as possible in a radial sense, and only in those places which are immediately under the influence of the magnetic field. Or, better still, we may abandon the disc shape of conductors altogether, and substitute an armature with a laminated iron core of the drum type, seen end on in Fig. 8, and use, instead of a straight magnet, a horse-shoe magnet, so shaped as to bring its poles,

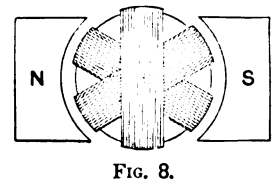

FIG. 8.

N S, to opposite sides of the drum, and wind the latter with a number of coils closed in themselves. If we now revolve the magnet, strong currents will be generated in each coil successively, and a very small torque will be exerted on the armature. The torque will, in fact, be comparable to that required to revolve an ordinary continuous current drum armature in a strong field, if we short circuit the brushes. Here, you see, we have, by applying a few very obvious improvements to the Arago disc, at once obtained a machine of very considerable power. Imagine both the magnet and the armature mounted on independent spindles (not shown in the diagram, but passing both at right angles through the centre of the figure), then it is perfectly clear that power given to the magnet spindle is transmitted, by electro-magnetic induction, to the armature ; and a large portion of it may, therefore, be obtained again from the armature spindle. Here we have, certainly, transmission of power, but not of the kind we require, since the distance of transmission is nothing. Now, what we want to do is to so alter our machine as to separate the two parts. We want the magnet in one place and the armature in another place, miles away, If, in this case, we succeed in transmitting rotation from the magnet to the armature, then we shall have solved the problem. This problem has been solved by an Italian electrician, Prof. Gallileo Ferraris, of Turin, who, early in 1888, communicated to the Turin Academy the results of his investigation on rotating magnetic fields produced by alternating currents. To clearly see the bearing which Ferraris's investigation has on our problem, let us inquire what it is we want at the motor station. We want there an armature, as shown in Fig. 8, and a magnetic field, the lines of which shall pass through the armature, and shall revolve round its centre. Whether the field is due to a real magnet, or is produced by any other means, is immaterial ; and it is the merit of Ferraris to have shown us how to produce such a revolving field without the use of a real magnet, but simply by the use of two distinct alternating currents passing through fixed coils.

As the subject is new, and will not be found in any of the numerous text-books dealing with electrical engineering, you will, per-

Digitized by Google

haps, not think it out of place if I put it before you in rather an elementary manner, beginning with the simplest possible case, and passing gradually to the more complicated cases. Assume, then, a combination of apparatus, as shown in Fig. 9. Here you have, on the left, an annular iron core wound with two coils, which are connected in series, and to a pair of line wires going to a similar coil on the right, which may be at any distance. Into the circular space enclosed by the first coil we put a straight bar magnet, N S, which can revolve round the centre. As the poles sweep past the wire turns, an E.M.F. is induced, and a current is caused to flow, the direction of which changes twice in every revolution. We have here, in fact, an ordinary alternate current generator, with stationary armature and revolving field magnet. By suitably proportioning and placing the various parts of the apparatus, we can make the E.M.F. and the current curve of a true sine character; and, in order to simplify the treatment, I shall assume that in this, and in the cases which follow, the design is such that all the E.M.F. and current waves follow the sine law. The alternating current, in passing through the coils on the right, magnetise the iron core, so

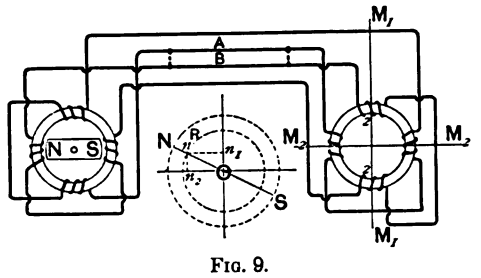

Fig. 9.

as to develop north and south polarity in the line M_1 M_1. The effect is the same as if we placed into the ring a vertical magnet which is collapsible, the two poles shrinking into a point at the moment that the current strength is zero, and coming apart vertically as the current increases. We must imagine this magnet alternately shrinking into nothing and growing larger and stronger; also reversing its polarity each time that it passes through its zero condition. In the apparatus shown by Fig. 9, therefore, rotation of a real magnet on the left produces merely an oscillating magnetic field on the right. As you know, a magnetic field may be represented graphically, in direction and magnitude, by a straight line; and, in this particular case, the line so representing the oscillating field is the projection of the radius, O n, on the vertical M_1 M_1, if the length of the radius, O n, represents the strength of the field at maximum current. At the moment to which the diagram refers, our collapsible magnet will, therefore, have grown to the strength represented by the length, s_1 n_1; and, if there were no lag, the real revolving magnet would, at that moment, occupy the position, S N. As there must be some loss in the transmission, I have shown N at a larger radius than n. If there is lag, then n and N will not lie on the same radius, but n will occupy, say, the position n', and the strength of the oscillating field

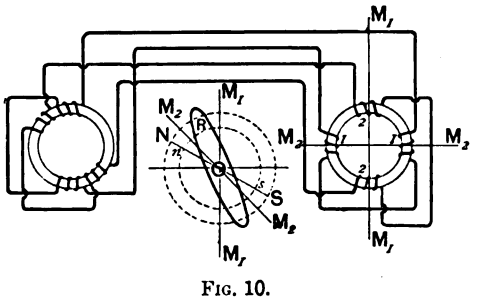

Fig. 10.

will be n_1', s_1'. The practical effect of lag is this, that the revolving magnet will have passed the vertical position shown in the diagram by the time the current has reached its maximum; and I can, therefore, eliminate the lag from the graphic diagram, by assuming that the revolving magnet has been shifted back through an angle equal to the angle of lag in this diagram, but left in its true position in the diagram representing the apparatus itself. In Fig. 9 the coils on the ring on the right hand are placed on the horizontal diameter. If, as in Fig. 10, I place them on the vertical diameter, the resulting oscillating field will be horizontal, namely, on the line, m_1 m_2; and the projection of n on the vertical must be taken over to the horizontal, as shown by the dotted quarter circle. Let us now suppose that we have both horizontal and vertical coils on the ring, as shown in this figure, then the combined effect of these coils willl be to produce an oscillating field on the line, R R, the strength of the field being, as you will easily understand, about 40 per cent. greater than in either of the former cases; but still the field is not a revolving one. I can show you the production of an oscillating field, as here explained, by means of a mechanical model.

Up to the present, then, we have not advanced in the solution of our problem. We have produced at the distant point an oscillating field; but what we want there is a revolving field; and to get this we must duplicate the apparatus shown in Fig. 9, by putting horizontal coils on the generator and vertical coils on the motor ring, in addition to the coils already there. This arrangement is shown in Fig. 11. Now, the field produced by the coils, 1 1, is given by the projection of O n on the vertical; and that produced by the coils 2 2 is given by the projection of O n on the horizontal. The resultant of these two fields is therefore O n, the point n revolving round O as a centre on the circle R. The effect of revolving a real magnet within the generator ring is, then, to produce a revolving magnetic field of the strength O n within the motor ring, a kind of revolving phantom magnet which, for our purpose, is quite as suitable as a real magnet. I can also show you this effect by means of the mechanical model.

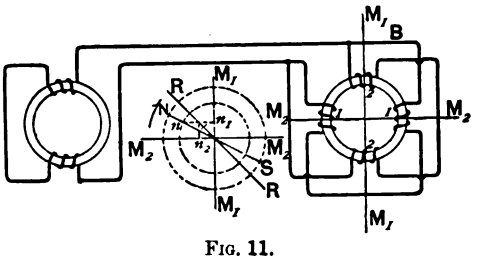

Fig. 11.

You observe that in Diagram 11 four wires are shown, connecting the generating and receiving machines. Now, as the absolute potential of any of these wires may be chosen arbitrarily, there is obviously nothing against choosing it at such a value as will make it coincide with the absolute potential of another wire not belonging to the same circuit. We might thus, for instance, equalise the potential between the wires A and B by connecting them at either terminus, as shown by dotted lines, and not disturb in any way the satisfactory working of the machines. Or, better still, we may omit one of the wires altogether, and use the other as a common wire for both circuits, and thus reduce the total number of wires to three. The common wire must, however, have about 40 per cent. more carrying capacity, since the algebraical sum of the two currents is 1·4 times the strength of each current taken singly. Here you have, then, the theoretical solution of the problem of how to transmit power by alternating currents, as indicated by Ferraris, but the first to attack this problem practically was Mr. Tesla, an American electrician, and such motors are, therefore, also known under the name of Tesla motors, though the name "Ferraris motors" seems to me to be more appropriate, as distinguishing this motor from the two-wire Tesla motors, about which I shall say something presently. To carry out a power transmission by means of such a system, we must have at the generating station an alternator, the armature of which is wound with two circuits giving currents with a quarter period phase difference, three-line wires, and a motor having a laminated field magnet, which is excited by coils placed alternately in the two circuits so as to produce a

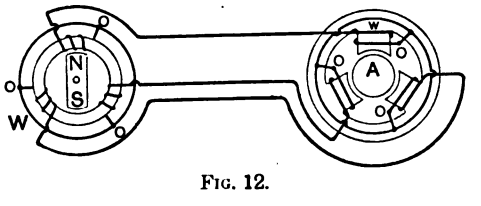

Fig. 12.

revolving field. The armature of this motor must have an iron core, surrounded with coils closed in themselves.

The necessity of using three-line wires is, to a certain extent, a disadvantage of this system, and several engineers, Mr. Tesla foremost amongst them, have tried to improve the system in such a way that two-line wires only should suffice. The methods suggested have this in common, that all aim at producing a difference in phase between the currents passing through the motor, without the use of a second set of coils on the generator. If we insert, for instance, a large inductionless resistance into the branch B in Fig. 10, and a coil having very little resistance, but great self-induction, into the branch A, the current in the coils 1 1 will lag by a small amount behind the E.M.F. impulses of the generator, whilst the current in the coils 2 2 will lag behind these impulses by a larger amount. The phase difference between the two currents can, of course, not amount to 90deg., which angle is required for producing the best

Digitized by Google

effect, but some difference of phase can certainly be produced in this way. The arrangement will, in fact, be equivalent to that shown in Fig. 12, where the distance between the two sets of coils on the generator is less than 90deg.

An easy geometrical construction, which I need not explain at length, shows that in this case the path of either pole of what I have before called the revolving phantom magnet is an ellipse, but that it can be made to be circular by a dis-symmetrical arrangement of the coils on the motor, though in this case the diameter of the circle is much reduced. In either case the value of the machine as a power-producing appliance is also much reduced, whilst at the same time the efficiency must be low, owing to the waste of power in the resistance coil. I can also show you the action of this two-wire motor by means of the mechanical model.

(To be continued.)

VARIATIONS OF CONDUCTIVITY UNDER ELECTRICAL INFLUENCE.*

BY E. BRANLY.

In a preceding article I showed that certain substances undergo an increase in conductivity under various electrical influences, and that these substances are numerous. The increase in conductivity varies with the energy of the exciting source. If the electric influence is due to the passage of a continuous current, the increase in conductivity is greater the greater the electromotive force of the battery employed. There is, however, no proportionality, the increased conductivity growing more rapidly than the number of cells, and tending quickly to a maximum. If the electric action consists in the passage of discharge currents in metallic rods, as in arrangment A (Fig. 1), the conductivity increases with the length of spark at S, and it also increases when the rods are brought nearer the sensitive substance. Successive sparks are additive in their effects, although, if the action of the first one has been very powerful, the resistance is sometimes almost immediately reduced to a minimum.

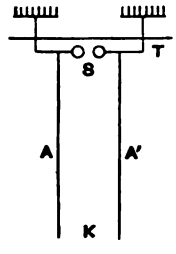

FIG. 1.

Restoration of Original Resistance.—The conductivity caused by the various electrical influences lasts sometimes for a long period (24 hours or more), but it is always possible to make it rapidly disappear, particularly by a shock.

The majority of substances tested showed an increase of resistance on being shaken previous to being submitted to any special electrical influence, but after having been influenced the effect of shock is much more marked. The phenomenon is best seen with the metallic filings, but it can also be observed with metalised ebonite sheets with mixtures of liquid insulators and metallic powders, mixtures of metallic filings and insulating substances (compressed or not compressed), and finally with solid bodies.

I observed the return to original resistance in the following manner :—The sensitive substance was placed at K (Fig. 1), and formed part of a circuit which included a Daniell cell and galvanometer. At first no current passes. Sparks are then caused at S, and the needle of the galvanometer is permanently deflected. On smartly tapping the table supporting the ebonite cap in which the sensitive substance is contained, the original condition is completely restored. When the electric action has been of a powerful character, violent blows are necessary. I employed for the purpose of these shocks a hammer fixed on the table, the blows of which could be regulated.

With some substances, when feebly electrified, the return seemed to be spontaneous, although it was slower than the return of the galvanometer needle to equilibrium. This restoration of the original resistance is attributable to surrounding trepidations, as it was only necessary to walk about the room at a distance of a few metres, or to shake a distant wall. This spontaneous return to original resistance after weak electrical action was visible with a mixture of equal parts of fine selenium and tellurium powders. The restoration of resistance by shock was not observable so long as the electrical influence was at work.

After having been submitted to powerful electric action, shock does not seem to entirely restore substances to their original state, in fact, the substances generally show greater sensitiveness to electric action. Thus, a mixture of colza oil and antimony powder being exposed to the influence of arrangement A, a spark of 5mm. was at first necessary to break down the resistance, but after the conductivity had been made to disappear by means of blows, a spark of only 1mm. was sufficient to again render the substance conducting. Finely powdered aluminium has an extremely high resistance. A vertical column of powdered aluminium 5mm. long of 4 sq. cms. cross-section, submitted to considerable pressure, completely stopped the current from a Daniell cell. The influence of arrangement A produced no effect, but, by direct contact with a Leyden jar, the resistance was reduced to 50 ohms. The effect of shock was then tried, and after this the sparks produced by arrangement A were able to reduce the resistance.

The following experiment is also of the same kind. Aluminium filings placed in a parallelipidic trough completely stopped the current from a Daniell cell, and the resistance offered to a single cell remained infinite after the trough had been placed in the circuit of 25 sulphate of mercury cells for 10 seconds. The aluminium was next placed in circuit with a battery of 75 cells ; a single Daniell cell was then able to send a current through the substance. The original resistance was restored by shock, but not the original condition of things, since a single cell was able to send a current after the aluminium had been circuited for 10 seconds with a battery of only 25 cells. I may add that if the restoration of resistance was brought about by a *violent* shock, it was necessary to place the aluminium in circuit with 75 cells for one minute before the resistance was again broken down.

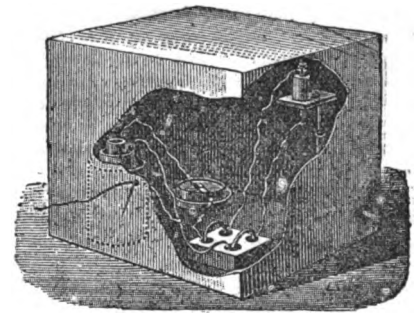

FIG. 2.

It must be observed that electrical influence is not always necessary to restore conductivity after an apparent return to the original resistance, repeated feeble blows being sometimes successful in bringing this about. Both in the case of slow return by time and sudden return by shock, the original value of the resistance is often increased. Rods of Carré carbon, 1 metre long and 1mm. in diameter, were particularly noticeable for this phenomenon.

Return to Original Resistance by Temperature Elevation.—A plate of coppered ebonite rendered conducting by electricity, and placed close to a gas jet, quickly regained its original resistance. A solid rod of resin and aluminium, or of sulphur and aluminium, rendered conducting by connection to the poles of a small battery will regain its original resistance by shock, but if the conducting state has been caused by powerful means, such, for instance, as direct contact with a Leyden jar, shock no longer has any effect, at least such a shock as the fragile nature of the material can stand. A slight rise of temperature, however, has the desired result. By suitably regulating the electric action it is possible to get a substance into such a condition that the warmth of the fingers suffices to annul conductivity.

Influence of Surroundings.—Electric action gives rise to no alteration of resistance when the substance is entirely within a closed metal box. The sensitive substance, in circuit with a Daniell cell and a galvanometer, is placed inside a brass box (Fig. 2). The absence of current is ascertained, the circuit broken, and the box closed. A Wimshurst machine is then worked a little way off, and will be found to have had no effect. The same result will be obtained if the circuit is kept closed during the time the Wimshurst

* Abstract from *La Lumière Electrique*. For abstract of the first portion of this article see *The Electrician*, June 26, p. 220.

Digitized by Google

machine is in operation. If a wire connected at some point to the circuit is passed out through a hole in the box to a distance of 20 to 50 cms., the influence of the Wimshurst machine makes itself felt. On tapping the lid to restore resistance the galvanometer needle remains deflected so long as the sparks continue to pass. If, however, the wires are pushed in so that they only project a few millimetres, the sparks still passing, a few taps suffice to bring back the needle to zero. On touching the end of the wire with the fingers or a piece of metal conductivity is immediately restored. The movements of the galvanometer needle were rendered visible in these experiments by looking through a piece of wide mesh wire gauze with a telescope. The respective position of the things was also reversed ; that is to say, a Ruhmkorff coil and a periodically discharged Leyden jar were placed inside, and the sensitive substance outside, the box, with the same results.

In some later experiments with a larger metallic case, and with the Daniell cell, sensitive substance, delicate galvanometer, and Wheatstone Bridge placed inside, I found that a double casing was necessary in order to absolutely suppress all effects. A glass covering afforded no protection.

Considerations on the Mechanism of the Effects Produced —What conclusions are we to draw from the experiments described ? The substances employed in these investigations were not conductors, since the metallic particles composing them were separated from each other in the midst of an insulating medium. It was not surprising that currents of high potential, and especially currents induced by discharges, should spark across the insulating intervals. But as the conductivity *persisted* afterwards, even for the weakest thermo-electric currents, there is some ground for supposing that the insulating medium is transformed by the passage of the current, and that certain actions, such as shock and rise of temperature, bring about a modification of this new state of the insulating body. Actual movement of the metallic particles cannot be imagined in experiments where the particles in a layer a few millimetres thick, were fixed in an invariable relative position by extreme pressures, reaching at times to more than 100 kilogrammes per sq. cm. (1,420lb. to the square inch). Moreover, in the case of solid mixtures, in which the same variations of resistance were produced, displacement seems out of the question. To explain the persistence of the conductivity after the cessation of the electrical influence, are we to suppose in the case of metallic filings a partial volatilisation of the particles creating a conducting medium between the grains of metal? In the case of mixtures of metallic powders and insulating substances agglomerated by fusion, are we to suppose that the thin insulating layers are pierced by the passage of very small sparks, and that the holes left behind are coated with conducting material ? If this explication is admissible for induced currents, it must hold good for continuous currents. If so, we must conclude that these mechanical actions may be produced by batteries of only 10 to 20 volts electromotive force, and which only cause an insignificant current to pass. The following experiment is worth quoting in this connection :—

A circuit was formed by a Daniell cell, a sensitive galvanometer, and some aluminium filings in an ebonite cup. The galvanometer needle remained at zero. The filings were cut out of this circuit, and switched for one minute into circuit with a battery of 43 sulphate of mercury cells. On being replaced in the first circuit, the filings exhibited high conductivity. The result was the same when 10 or 20 cells were employed, or when the current was diminished by interposing in the circuit a column of distilled water, 40cm. long and 20mm. in diameter. The cells used (platinum, sulphate of mercury, sulphate of zinc, zinc) had a high internal resistance. Thus, 43 cells (60 volts), when short circuited, only gave a current of 5 milliamperes. The same battery, with the column of distilled water in circuit only, caused a deflection of 100mm. on a scale one metre off, with an astatic galvanometer wound with 50,000 turns. We can, therefore, see how infinitesimally small the initial current must have been when the filings were added to the circuit. The battery acted, therefore, essentially by virtue of its electromotive force.

If mechanical displacement of particles or transportation of conducting bodies seem inadmissable, it is probable that there is a modification of the insulator itself, the modification persisting for some time by virtue of a sort of "coercive force." An electric current of high potential, which would be completely stopped by a thick insulating sheet, may be supposed to gradually traverse the very thin dielectric layers between the conducting particles, the passage being effected very rapidly if the electric pressure is great, and more slowly if the pressure is less.

Increase of Resistance.—An increase of resistance was observed in these investigations less often than a diminution ; nevertheless, a number of frequently repeated experiments enable me to say that increase of resistance is not exceptional, and that the conditions under which it takes place are well defined. Short columns of antimony or aluminium powder when subjected to a pressure of about 1 kilogramme per sq. cm. (14·2lb. per square inch), and offering but a low resistance, exhibited an increase of resistance under the influence of a powerful electrification. Peroxide of lead, a fairly good conductor, always exhibited an increase ; so also did some kinds of platinised glass, while others showed alternate effects. For instance, a sheet of platinised glass, which offered a resistance of 700 ohms, became highly conducting after 150 sulphate of mercury cells had been applied to it for 10 seconds. This condition of conductivity was annulled by contact with a charged Leyden jar, and reappeared after again applying 150 cells for 10 seconds, and so on. Similar effects were obtained with a thin layer of a mixture of selenium and tellurium poured, when fused, into a groove in a sheet of mica placed between two copper plates. These alternations were always observed several times in succession, and at intervals of several days.

These augmentations and alternations are in no way incompatible with the hypothesis of a physical modification of the insulator by electrical influence.

ACCUMULATOR TRACTION.

The following figures, extracted from the recent report of the Directors of the Birmingham Central Tramways Company, are perhaps the most reliable that have hitherto been published on the important question of the actual cost of accumulator traction. These figures are rendered all the more valuable owing to the detailed manner in which they are set out, and the fact that the same company also employs horse, steam, and cable cars on an extensive scale.

Miles Run and Passengers Carried.

System.	Miles run.	Passengers carried.	Passengers carried per car mile.
Steam	1,184,401	14,242,827	12·02
Horse. Tramways	131,528	1,114,388	5·3

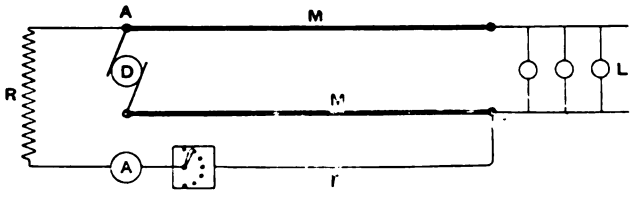
THE REGULATION OF ELECTRICAL DISTRIBUTION FROM CENTRAL STATIONS.*

BY J. LAFFARGUE.

It is of the highest importance, as every one knows, to ensure constant potential or constant current, as the case may be, in electrical distribution from central stations, and I propose to examine in the same way as did Herr Imhoff, in a recent issue of the *Elektrotechnische Zeitschrift*, the principal methods hitherto adopted in constant potential systems.

Practice has shown that, in order to ensure good regulation, it is necessary to keep the difference of potential at the station constant to within one or two volts. In small installations, where the demand is all or nothing, there is no difficulty. But in the case of central stations considerations such as first cost and depreciation often result in the employment of mains in which as much as 15 volts are lost with maximum load. I will not detail the various systems of distribution which have been devised to secure constant potential, but will suppose that regulation at the dynamo terminals is sufficient, and to avoid complication I will take a feeder installation. In this system the problem is to maintain a constant difference of potential at the points of junction of the feeders with the supply circuits. Let us now examine the different methods adopted up to the present day.

1. *Regulation by Altering the Resistance of the Exciting Circuit.*—In the case of a single machine one can regulate the difference of potential by introducing or cutting out resistance in the exciting circuit. This regulation is carried out according to the indications of a voltmeter or pilot-lamp connected to the extremities of the system. In the case of distribution by feeders this method keeps the difference of potential at the station constant whatever may be



the loss in the feeders, which have, however, their own regulating appliances. When the machines are connected in parallel the regulation of the exciting circuit allows the load to be divided between them all, and the potential to be kept constant at the same time.

2. *Regulation by Introducing Resistance into the Main Circuit.*—If E be the difference of potential at the terminals of the central station dynamo, R the resistance of the line, C the current, we have for e the difference of potential at the end of the line,

$$e = E - CR.$$

As e varies according to C, it is necessary to vary R in the inverse direction in order to keep C R constant. This method has been employed by Menges, Graner, Lahmeyer, Schuckert, and others.

3. *Regulation by Accumulators.*—Regulation by means of accumulators can be carried out in several ways. They can be put in series in the main circuit and their number varied as required. The accumulators in this case play the part of ordinary resistances. We can also charge accumulators in series and discharge them in parallel, varying the number in each group. Examples of this method are the central stations in the Rue de Bondy and in the Rue des Filles Dieu in Paris, and the Chelsea Electricity Supply Company station in London.

4. *Regulation by an Auxiliary Dynamo.*—This method, advocated by Prof. Perry and put into practice by Herr Lahmeyer, consists in introducing an auxiliary dynamo into the main circuit. At a constant speed this dynamo produces an additional electromotive force proportional to the strength of the main current, and, therefore, proportional to the fall of potential on the circuit, so that the difference of potential remains constant. This method of working has the advantage over the others of not uselessly expending energy.

5. *Regulation at the end of the line.*—Herr Imhoff points out a new method of regulation, which consists in completing the exciting circuit by a wire connected to the far end of the leads. From the dynamo D (see Fig.) run the two leads. The exciting circuit starts from the pole A and includes the resistance R, an ammeter, and a variable resistance. Let M M be the resistances of the mains, r that of the return wire; L the resistance of the lamps, &c., C the strength of the main current, c that in the exciting circuit; E the difference of potential at the terminals of the dynamo, and e that at the extremity of the line. We then have

$$C = \frac{E}{2M+L} \text{ and } c = \frac{E}{R+r+M}$$

when the variable resistance = 0.

From this we get

$$\frac{c}{C} = \frac{\frac{E}{R+r+M}}{\frac{E}{2M+L}} = \frac{2M+L}{R+r+M}$$

$$c = C \times \frac{2M+L}{R+r+M};$$

but $$L = e/C \quad \ldots\ldots\ldots (1).$$

whence we have $$(R+r+M)c = C(2M+e/C),$$

whence $$e = (R+r+M)c - 2CM \quad \ldots\ldots (2).$$

Now it is e which ought to remain constant.

From (2) we have

$$e = c(M+R) + cr - 2CM;$$

now $$c(M+R) = \text{a constant} = K,$$

$$\therefore \quad e = K + cr - 2CM.$$

Now, for e to remain constant, $cr - 2CM$ must remain constant, which obtains when

$$cr = 2CM;$$

whence $$r = 2CM/c \quad \ldots\ldots\ldots (3).$$

The condition imposed by equation (3) is the following:—To keep a constant difference of potential at the distant end of the line, the fall of potential along the return wire must equal the total fall. To fulfil this condition, it is only necessary to vary r within certain limits. To effect this, a variable resistance is inserted in the exciting circuit.

This method, which it is easy to realise in practice, does not require more expensive apparatus than other methods. On the other hand, it permits us to realise the economy of a return wire. I think it worth while to call attention to this method on account of its convenience and practical facility.

* From *L'Electricien*.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 8, 1891.

Fire at a Central Station.—One of the most disastrous fires that has taken place in an electrical establishment for some time occurred on Monday evening last, and resulted in the total destruction of the plant of the Richmond Light, Heat, and Power Company, at St. George, Staten Island. The flames were first noticed under the eaves of the boiler house about 8:30 in the evening, and an immediate attempt was made to suppress the fire. The Company had several hose lines attached to its fire-plugs, and these were at once brought into use, but, to the consternation of everybody, there was no water. The Staten Island Water-Supply Company had not pressure enough in its pipes to force the water through the hundred feet of hose, much less to carry it on to the flames. Before the fire-engines could be brought to the scene and into action the flames had made such headway that little could be done; gradually they passed from the boiler-room to the dynamo-room, and in spite of all efforts nothing could be done to save the plant, which was completely destroyed. The buildings burned were two, the boiler-house and the adjoining building, containing the dynamos. The former contained two 300, one 100, and three 80 H.P. boilers. The engines were one 700 H.P. Corliss, and two 80 H.P. smallhigh-speed engines. Eight dynamos of Westinghouse, Fort Wayne, American, Thomson-Houston, and Edison makes were burned. The total loss amounts to $75,000, about $50,000 of which was covered by insurance. Efforts were at once made to resume the lighting service with temporary apparatus. The Fort Wayne Electric Company offered to furnish 10 or 12 dynamos within 48 hours, and thus the electrical end of the new equipment was looked out for. Engine-power, however, was not quite so easily furnished, although several manufacturing establishments near have spare steam, which will probably be utilised. It is expected that light will be turned on again by Saturday night. The

Digitized by Google

cause of the fire is as yet unknown; it is supposed to have been due to defective smoke flues. Despite the unfriendly remarks of insurance companies, electrical plants have proved to be, on the whole, very fair risks. There have been, aside from the present, but two plants of any magnitude destroyed within the present year; both of these were electric railway installations, one at Pittsburgh, Pa., and the other at Asbury Park, N.J. In neither case was the fire electrical in its origin.

The New York Rapid Transit Commission.—Some ugly rumours are going the rounds regarding the doings of the Rapid Transit Commission. When it first began its prolonged, and so far fruitless, lucubrations, plans from various engineers were called for, and a large number responded, elaborating more or less perfect systems for underground and overhead structures suited to the needs of the case. Many of the engineers who furnished these designs spent a large amount of time and money in getting up drawings and specifications of a very complete character. It now transpires that the engineers of the Commission are working up plans of their own, which will be foisted upon the public in due season. They claim to have secured the services of several noted engineers for consultation, but although these prove to be gentlemen of repute in their profession, they are far from being specialists in underground construction, one of them being a well-known bridge engineer, and another making a speciality of buildings. It looks very much as if the engineers of the Commission saw an excellent opportunity to make a reputation by the use of other people's brains, and were preparing to seize this opportunity quite irrespective of the rights of these others. It remains to be seen how far they will draw upon the various plans suggested, and what credit, if any, they will give to the authors of the various valuable suggestions that have been thrown out. Of course, it is necessary, as I have remarked before, for the Rapid Transit engineers to make a show of earning their salaries, but the public will not be very well pleased if they take this particular means of doing it.

Storage Battery Traction.—It is reported that storage battery cars will soon be running on the Fourth-avenue line again, and this is connected with a rumour of an approaching consolidation between the United States Electric Traction Company and the Julien Company, now sole licensee under the Brush patent, which has been recently sustained. Meanwhile other inventors in storage battery work do not seem to be appalled by the decision in favour of Brush, but are going on in various lines of work. Mr. C. P. Elieson, well known to you from his connection with storage battery traction in London, is now making some preparations to enter upon practical work here. At another time I may be able to give full details of what he is doing. Of the Waddell-Entz system that was lately described in the *Electrical World*, nothing more is heard. One or two more successful demonstrations have been made, but nothing commercial as yet.

TRADE NOTES AND NOTICES.

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all. Vol. I., 20; Vol. II., 18), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

COMPETITION.—The New Promenade Pier and Torquay Ferry Company offer a prize of £25 for the best size, design, and arrangement for new steam or electric launches for the passenger and parcels traffic between Paignton Promenade Pier and Torquay. The prize is to be awarded at the sole discretion of the subscriber, and all designs submitted to be his property and to be used as he may please. Further particulars are given in our advertisement columns, and full information and conditions can be obtained on application to the subscriber, Mr. Wm. Robertson, Managing Director of the Company, Paignton, South Devon. All designs have to be in on or before Saturday, September 5th next.

PLANT FOR SALE.—Our advertisement columns contain particulars of a complete private electric lighting plant for sale, in consequence of owner obtaining current from Central Supply Station.

VACANT APPOINTMENTS.—The Electricity Committee of the Vestry of St. Pancras invite applications for the following appointments:—Chief clerk of the electricity department, salary £150 per annum; resident engineer, central station at Regent's Park, £4 per week; engine driver, £3 per week; electrician for dynamos and switchboards, £3 per week; stoker, 35s.; stoker, 25s. per week; inspector of private works, £2. 10s. per week. Applications are to be made in writing on forms to be had on application at the Vestry Hall, and are to be sent with testimonials not later than Wednesday, the 26th inst. Further particulars are given in our advertisement columns.

——— The Urban Sanitary Authority of Bath propose to appoint an electric inspector, under the terms of the Bath Electric Lighting Licence of 1890. The licence and a plan of the compulsory and permissive electric area may be inspected at the office of Mr. F. H. Moger, clerk, 3, Wood-street, Bath. Applications for the appointment, stating remuneration required, with testimonials as to qualification, to be sent addressed to the clerk, on or before Friday, the 28th inst. Further particulars will be found in our advertisement pages.

THE KEYS' ELECTRIC COMPANY.—We have received from this Company a very exhaustive catalogue, in 35 divisions, of general electrical plant and apparatus. In this handy form the catalogue will be found very useful to the trade. Each division is fully illustrated, and includes a description and price list of the apparatus to which the section is devoted. The various parts refer to the following manufactures:—Motors, regulators, arc lamps, arc lamp suspension gear, carbons, measuring instruments, physical, electrical, and magnetic instruments, incandescent lamps, lampholders, switch-boards, main switches, safety switches and fuses, cut-outs, insulators, wires and cables, dynamos, dynamo fittings, accumulator plants, and electric launches. One division is specially devoted to theatre lighting and specialities for use therein.

THE ELECTRIC LIGHT AT EXETER.—The Exeter Literary Society have just had completed an installation of the electric light in their new lecture hall and adjacent building. The main hall is well lighted by 33 Edison-Swan lamps of 32 and 16 c.p., the lamps being enclosed in acid-ground shades. The lights on the stage are connected to wall-sockets with a sufficient length of flexible cord to allow of their being utilised as foot-lights or battens, the total number of lamps installed being about 90. The installation was carried out and current supplied by the Exeter Electric Light Company, which is now running an equivalent of nearly 3,000 8 c.p. lamps and 26 arcs.

THE TELEPHONE AT RIFLE MEETINGS.—At the meeting, on August 14th and 15th, at Altcar, Liverpool, of the County Rifle Association six sets of telephone instruments were erected by the National Telephone Company (Liverpool district) between the firing points and the targets on the 200, 500, and 600 yards ranges. They were much used for communicating with the markers.

MESSRS. DRAKE AND GORHAM.—The Governors of Felstead School have decided to introduce the electric light throughout the whole of the buildings under their control, and have placed the contract with Messrs. Drake and Gorham. The installation will consist of about 460 lamps, which will be supplied by two separate engines.

MESSRS. ARMFIELD AND CO.—From this firm we are in receipt of illustrated particulars of their "British Empire" turbine, for which a number of advantages are claimed. The makers state that it is easy to stop and start, and is especially suitable for variable streams. Illustrations accompany the particulars showing a double turbine with double horizontal gates, and a single turbine with a single horizontal gate, as well as turbines with single vertical gates.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

July 27, 1891.

12,703. T. HAWKINS. London. Improvements in or connected with switch-boards for electrical purposes.

12,702. A. T. SNELL. London. Improvements in electric coal-cutting machine.

12,726. W. P. THOMPSON. Liverpool. Improvements in the construction armatures for certain kinds of electrical machines. (W. Lahmeyer and Co., Germany.)

12,731. C. S. F. MELLOR. London. An automatic locomotive or electrical engine.

12,727. W. P. THOMPSON. Liverpool. Improvements in the method or means of regulating motor-dynamos or continuous current transformers. (W. Lahmeyer and Co., Germany.)

July 28, 1891.

12,774. O. FRANCIS. London. A new electro dia-magnetic self-rotating dynamo.

Digitized by Google

12,792. A. W. KING. London. An improved bolt socket electric light switch.
12,799. M. FEILBOGEN. London. Improvements in and relating to system of electric distribution.
12,824. G. ZANNI. London. An improvement connected with electric lighting apparatus.
12,828. H. H. LAKE. London. Improvements relating to electric motors chiefly designed for railway and other vehicles, and to electric generators. (The Thomson-Houston International Electric Company, United States.)
12,831. W. RUSSELL. London. Improved curative electric belt.
12,334. W. W. HORN. London. An improved electric apparatus for treating deafness. (G. F. Webb, United States.)

July 29, 1891.

12,859. G. WILSON. Bristol. A method of and means for combining at will telephonic communication with ordinary methods of electrical signalling in or about coal and other mines and works and other places.
12,898. T. PARKER. London. Improvements in means to be employed in the electrical deposition of copper.

July 30, 1891.

12,904. R. A. SCOTT. London. Improvements in holders for incandescent electric lamps.
12,934. A. R. BENNETT. London. An electrical parcel exchange system.
12,946. J. A. TIMMIS and W. H. WALEUN. Improvements in the electro-deposition of platinium.
12,960. W. M. MORDEY. London. Improvements in electric transformers.

July, 31, 1891.

12,982. F. G. M. WETHERFIELD. London. An electric automatic time check. (C. K. Jardine, Demerara.)
12,985. R. B. ANNESLEY, J. H. EVANS, and E. BLAKEY. London. Improvements in means or apparatus for use in automatic electric railway signalling.
13,015. G. H. GRAHAM and T. GANNANE. London. Improved electric insulator.

August 1, 1891.

13,087. A. M. ELTON. London. Improvements in electric apparatus for maintaining a uniform, or approximately uniform, temperature within a chamber or vessel, specially applicable to incubators.
13,096. J. A. MCMULLEN. London. Improvements relating to conduits, applicable for combined use as casings for electrical conductors, and for gas supply, or for either use separately.
13,114. T. PARKER. London. Improvements in or connected with electric furnaces.
13,124. H. HOWARD. London. Improvements in heating and welding by electricity.
13,125. H. HOWARD. London. Improvements in carbon holders and screens, suitable for electric welding.

August 4.

13,163. W. BLENHEIM. Egham. Improvements in carbon transmitters for telephonic purposes.
13,167. T. D. WILLIAMS. Blackburn. Showing when the bell of a telephone has been ringing, or "a sight indicator for telephones."
13,171. J. CRIGGAL, J. BERKLEY, and C. F. WILLIAMSON. London. An improved socket for incandescent electric lamps.
13,200. G. C. DYMOND. Liverpool. Improvements in fence posts, telegraph posts, or the like. (F. P. Rosback and H. F. Band, United States).
13,208. E. CASPER. London. Improvements in the manufacture of wire, bars, bands, and sheets of copper by electrolysis, and in apparatus therefor. (E. Piarengo, Italy).
13,250. W. H. WHEATLEY. London. Improvements in electrical switches and safety fuses. (A. Ashfalck, Germany).
13,252. C. FÉRY and E. DUCRETET. London. Improvements in electrical contact making and breaking devices.
13,268. W. W. HORN. London. Improvements in electrical fire alarms. (B. W. Leonard and J. C. Nichols, United States).
13,269. E. A. GIMINGHAM. London. An improvement in connecting the conductors of electrical glow lamps.

August 6, 1891.

13,274. P. E. SINGER. London. Improvements in electric meters.
13,315. J. Y. JOHNSON. London. Improvements in arc lamps. (C. Bellens, France).
13,331. M. G. KELLOGG. London. Improvements in telephony, and apparatus therefor.

August 7, 1891.

13,335. L. H. CLINE. Hull. Electric tell-tale for the control of masthead, stern, and side lights on steamers.
13,362. G. FORBES. London. Improvements in dynamo-electric machines.
13,366. J. D. MASSEY. London. Improved telephone transmitter.
13,367. T. B. SLOPER. London. Improvements in electric telephone switches and systems.
13,371. H. H. LEIGH. London. Improved electro-manual devices for the actuation of gravity signal arms, points, and the like. (A. Hillairet and A. Hugnet, France.)
13,372. A. H. BYNG. London. An improved electric or galvanic brush.
13,384. G. FORBES. London. Improvements in electrical contacts.
13,387. J. H. CAZAL. London. Improvements in dynamo-electric generators.

August 8, 1891.

13,437. A. J. HOWES. London. An improved method of, and means for, electrical communication between parts of railway trains.
13,446. W. J. S. BARBER-STARKEY. London. An improvement in secondary voltaic batteries.

August 10, 1891.

13,465. W. GADD and O'DREY. Manchester. Improvements in electrical automatic stopping apparatus for weft pile cutting machines.
13,492. F. E. ELMORE. London. A method and apparatus for electrical propulsion of vehicles.
13,503. M. VON DOLIVO-DOBROWOLSKY and the COMPANY ALLGEMEINE ELEKTRICITÄTS GESELLSCHAFT. London. Improvements in electric machines and apparatuses for differential phase alternating currents.

August 11, 1891.

13,528. A. DOUGLASS. London. Improved electric time-registering apparatus for use in cabs and the like.
13,529. J. A. BRIGGS. London. Improvements in methods and apparatus for obtaining and utilising electric light.
13,553. W. MITCHELL. London. Improvements in electrically-heated ovens.
13,554. W. MITCHELL. London. Improvements in electric steam generators.
13,558. J. CAUDERAY. London. Improvements in unipolar continuous current magneto or dynamo electric machines.

August 12, 1891.

13,589. G. E. HEYL. Berlin, C., Germany. Improvements in electric conductors.
13,627. W. B. BRAIN and A. J. ARNOT. London. An improved alternating electric current motor.

August 13, 1891.

13,628. W. HARTNELL. Leeds. Improvements in dynamos for generating electricity.
13,657. H. NEHMER. London. An adhesive voltaic plaster.

August 14, 1891.

13,692. A. H. MITCHEL-JONES. Manchester. Improvements in electric arc lamps.
13,705. A. SHIELS. Glasgow. An improved coupling for connecting electric wires.
13,714. H. W. MILLER. London. Improvements in and relating to apparatus for measuring electric currents.
13,753. A. M. CLARK. London. Improvements in telegraphic call-boxes. (J. G. Noyes, United States.)
13,754. W. S. RICHARDS and G. B. JAMES. London. Improvements in and relating to electric tramways and to vehicles therefor.

August 15, 1891.

13,802. J. SOHLMAN. London. Improved electric current generator for ordinary and multiple phase alternating currents.
13,809. G. HUGHES. London. New or improved machinery for covering wire conductors with leather. (E. E. Legrand, France.)

NEW COMPANIES, STATUTORY RETURNS, &c.

ANDERS, ELLIOT, AND CHETHAM-STRODE (LIMITED).—This Company was registered on the 11th August, 1891, with a capital of £5,000 in £1 shares, by E. J. Moeran, 89, Chancery Lane, W.C. The objects are: To acquire and take over as a going concern the business of electrical engineers and manufacturers of telegraphic and telephonic apparatus and appliances heretofore carried on by Anders and Elliot, at 10, Bush Lane, Cannon street, E.C., and Penarth-street, Old Kent-road, S.E., and with that view to carry into effect an agreement with C. H. Elliot and W. Chetham-Strode. To carry on the business of the above firm in all its branches, together with that of a Telegraph, Telephone, and Electric Light, Heat and Power Supply Company. The number of Directors is not to be less than two nor more than three, the first being C. H. Elliot, W. Chetham-Strode, and R. King, the first two being Managing Directors, with a salary of £200 per annum. Qualification of a Managing Director, £1,000; remuneration of ordinary Directors, £2. 2s. for each meeting attended. Office: 10, Bush Lane, Cannon-street, E.C.

F. W. BERK AND CO. (LIMITED).—Registered by W. H. E. Stone, Billiter-square-buildings, E.C., with a capital of £100,000 in £10 shares. Object: To acquire the undertaking of Messrs. F. W. Berk and Co., and to carry on in all its branches the business of importers, exporters, and manufacturers of chemical products, and other compounds appertaining thereto. None of the capital will be offered to the public.

BRITISH ELECTRO-CHEMICAL AGENCY (LIMITED). — This Company was registered on August 11, 1891, by Bonner, Wright, Thompson, and Co., Ingram House, 165, Fenchurch-street, E.C., with a capital of £75,000, divided into 2,500 vendors', and the remainder ordinary shares. The objects are: To enter into and carry into effect an agreement in the terms of a draft already prepared and expressed to be made between the Electric Construction Corporation (Limited) of the one part, and this Company for the other part, providing for the sale to the Company of certain patent rights. To purchase, or otherwise acquire, any other inventions relating to electricity, or the production or application thereof, or to any chemical, or electrical, or electrolytical, or electro-chemical process, or manufacture; or to any apparatus, implements, or machinery in connection with electricity; and to work and develop the said inventions, or any others that may be acquired. The number of Directors is not to be less than three, nor more than seven, the first being Mr. Joseph Ebbsmith, of Worcester House, Walbrook, E.C.; John B. Verity, of King-street, Covent Garden, W.C.; and J. Balfour, Savoy-hill House, W.C. Qualification, £250. J. Ebbsmith is the Chairman, and has a remuneration of £1,000 per annum. The remuneration of the other Directors is to be as follows: When less than 5 per cent. per annum is paid on the ordinary paid-up capital, £150 per annum each; when more than 5 and less than 10 per cent. is paid, £300 per annum each; when more than 10 per cent. is paid, £600 per annum each.

ELEKTRIZITATS-GESELLSCHAFT IN HAMBURG.—Under this title a Company has been formed in Hamburg, with a capital of M.1,200,000. The manager is Herr Hartogh, who has hitherto been the Hamburg representative of the Allgemeine Elektrizitäts Gesellschaft.

STEEL NUT COMPANY (LIMITED).—This Company was registered on August 11, 1891, with a capital of £5,000 in £5 shares, by Jordan and Sons, 120, Chancery-lane, W.C. The objects are: To carry on the trades or businesses of nut and bolt manufacturers, ironmasters, iron and steel manufacturers, manufacturers of screws, rivets, hinges, &c., tool makers, mechanical and electrical engineers. To acquire the undertaking of J. Hampton, the elder, and S. Partridge, trading under the name of the Patent Grinding and Polishing Machine Company, and to adopt a certain agreement, dated August 5, 1891, between J. Hampton, the elder, and S. Partridge of the one part, and J. A. Allen of the other part. The number of the Directors (unless otherwise determined) is not to be less than two nor more than five. Qualification, 50 shares. Remuneration, £50 per annum. J. Hampton and S. Partridge are the first Managing Directors. Solicitors: Slater and Co., Darlaston.

AKESTER ELECTRO-MOTOR AND ACCUMULATOR COMPANY (LIMITED).—The annual return of the above Company, made up to August 11, 1891, was filed on August 13th. The Company, which was registered on May 16, 1887, has a capital of £5,000 in £1 shares. All the shares have been taken up, and upon 1,500 16s. per share has been called. 3,500 shares have been considered as fully paid. The calls paid amount to £1,253. 8s., and unpaid to £46. 12s., £100 of which being paid in advance. Office: 36, Great James-street, Bedford-row, W.C.

BABCOCK AND WILCOX (LIMITED).—The registered office of this Company is situate at 114, Newgate-street, E.C.

BOURNEMOUTH AND DISTRICT ELECTRIC SUPPLY COMPANY (LIMITED).—An agreement made August 7, 1891, between the above Company and the Brush Electrical Engineering Company (Limited), cites that by a former agreement, dated June 4, 1891, between the same parties, it was agreed that the latter should sell, and the former should buy, the properties mentioned in that agreement, and in consideration, £17,275 in cash or fully paid-up shares, should be given to the vendors. The purchasers have agreed that the £17,275 is to be paid by the issue of 3,155 fully paid-up shares, and the balance in cash. The present agreement determines that on or before August 15, 1891, the shares mentioned above, and numbered 1 to 3,155, shall be allotted to the vendors or their nominees, and that the balance shall be paid in cash. (Filed on August 12, 1891.) Office: Observer Chambers, Albert-road, Bournemouth.

BYNG TELEPHONE COMPANY (LIMITED) (in Liquidation).—A meeting of the shareholders is to be held at 32, Mosley-street, Newcastle-on-Tyne, on September 17th, at 3 p.m., to receive an account of the winding up.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to July 30th, was filed on August 12, 1891. The Company, which was registered on August 19, 1879, with a capital of £400,000, has now a capital of £600,000 in £10 shares. All the shares have been taken up, the full amount called and all calls paid. The Eastern Telegraph Company (Limited) have taken 58,993 shares, and the Telegraph Construction and Maintenance Company (Limited), 600. Office: Winchester House, Old Broad-street, E.C.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to August 4th, was filed on August 10, 1891. The Company, which was registered on October 26, 1883, has a capital of £1,000,000, divided into 150,000 "A" and 50,000 "B" shares of £5 each. 89,261 "A," £3 paid, 17,139 "A" fully paid, and 23,564 "B" fully paid shares have been taken up, and upon the 89,261 "A" shares 10s. per share has been called and paid. The total amount agreed to be considered as paid on 89,261 "A" shares is £223,152. 10s., on 17,139 "A" shares £85,695, and on 23,564 "B" shares £117,820. The calls paid amount to £44,630. 10s., and the amount considered as paid is £426,667. 10s. Office: 100, Victoria-street, S.W.

ELECTRICAL ENGINEERING CORPORATION (LIMITED).—The office of this Company, which is in liquidation, is now situate at 58, Coleman-street, E.C.

EXCHANGE TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to August 12, 1891, was filed on the following day. The Company, which was registered on March 28, 1872, now has a capital of £246,250, divided into 8,125 "A" and 16,500 "B" shares of £10 each. 8,125 "A" and 16,200 "B" shares have been taken up, and upon 6,000 "A" shares £8 per share has been called and paid. £8 per share has been considered as paid on the remaining "A" shares, and the full amount on the 16,200 "B" shares, the whole amounting to £179,000. Office: 17 and 18, Cornhill, E.C.

GENERAL ZINC RECOVERY AND LIGHTING COMPANY (LIMITED).—At a meeting of shareholders held on July 14th, it was resolved, and at a meeting on August 7th it was confirmed, that the Company be wound up, and that Mr. J. M. Henderson, C.A., of 2, Moorgate-street buildings, E.C., be the liquidator.

IPSWICH ELECTRICITY SUPPLY COMPANY (LIMITED).—By an agreement made on July 2, 1891 (filed on August 12th), between Laurence, Scott, and Co. (Limited), and the above Company, the Ipswich Company agree to purchase the business of electrical engineers carried on by Laurence, Scott, and Co. at Norwich, Ipswich, and elsewhere, and in full satisfaction to pay them £1,069 in cash, and to allot to them or their nominees 1,431 fully paid-up £1 shares. Laurence, Scott, and Co. agree to abandon their Provisional Order under the Electric Lighting Acts 1882 and 1888, and the Ipswich Company will endeavour to obtain the confirmation of Parliament to their order. The Ipswich Company intend as soon as possible to increase their capital from £100 to £20,000. By an agreement made on July 2, 1891 (and also filed on August 12th), between the Brush Electrical Engineering Company (Limited) and the above Company, it is agreed that, in the event of the confirmation of Parliament to the Provisional Order of the Ipswich Company, the Brush Company shall have no interest in the other Company except as shareholders; and since the Brush Company have incurred expenses to the extent of £600 in connection with the application for the Provisional Order, and also in the promotion of the Ipswich Company, £50 in cash, £50 in cash within three months of the Parliamentary confirmation, and the allotment of 500 fully paid-up £1 shares, shall be deemed full satisfaction for all such expenses. Should the confirmation of Parliament not be granted, £50 fully paid up £1 shares shall be allotted to the Brush Company, or their nominees, in consideration of the said £600. Office: 112, Belvedere-road, Lambeth, S.E.

SHROPSHIRE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The capital of this Company has been increased by the addition of 100 founders' shares of £1 each to the registered capital of £25,000. The special resolution, of which the above is an abbreviated account, was passed July 2nd and confirmed July 27, 1891, and the notice to the Registrar of Joint Stock Companies was filed on August 13, 1891. Office: 9, The Square Shrewsbury.

SIEMENS BROTHERS AND COMPANY (LIMITED).—The annual return of this Company, made up to June 30, 1891, was filed on the same day The Company, which was registered on December 28, 1880, has now a capital of £500,000 in £100 shares. All the shares have been taken up and £85 per share been called thereon. All the calls are paid, amounting to £425,000. Office: 12, Queen Anne's-gate, S W. Alterations in the Articles of Association, Nos. 14 and 16, by special resolution, passed June 16, 1891, and confirmed July 6, 1891, were filed July 16, 1891.

TELEPHONE COMPANY OF AUSTRIA (LIMITED).—The annual return of this Company, made up to August 13, 1891, was filed on the following day. The Company, which was registered on April 27, 1883, with a capital of £100,000, has now a capital of £200,000, divided into 20,000 ordinary and 20,000 preference shares of £5 each. 11,703 ordinary and 7,358 preference shares have been taken up, and upon 150 of the ordinary, and the whole of the preference shares, the full amounts have been called and paid. The remaining ordinary shares have been considered as fully paid. The calls paid amount to £37,540, and the sum considered as paid is £57,765. Office: 53, New Broad-street, E.C.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the past week were £4,261.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The traffic receipts of this Company for the week ended August 16th amounted to £653.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended August 14th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company were £2,835.

THE ELECTRIC INSTALLATION AND MAINTENANCE COMPANY (LIMITED) (for the supply of electricity to the Crystal Palace, Sydenham, and district).—A prospectus of this Company was issued at the beginning of this week. The Company is established with a capital of £100,000, divided into 10,000 shares of £10 each, and we learn that the necessary capital has been privately subscribed. The Chairman of the Board of Directors is Colonel Lewis Vivian Loyd, D.L., J.P., and another Director is Mr. Joseph Pyke, who is also connected in that capacity with the London Electric Supply Corporation. The Manager is Mr. George Offor, the Secretary Mr. J. W. Barnard, and the Offices are at 4, Great Winchester-street, E.C. The objects of the Company will primarily be as follows:—(1.) To supply, by means of electric motors, the horse-power required by exhibitors at the forthcoming Electrical Exhibition at the Crystal Palace in the ensuing winter; and (2) To supply electricity for light and power purposes to the Crystal Palace and district surrounding it, under the powers contained in the Provisional Order granted them last year, and duly confirmed by Parliament. The engineers to the Company are Messrs. J. E. H. Gordon and Co., who also act as contractors, and who take three-fifths of the contract price of the works in shares and debentures. An arrangement has been entered into with the Crystal Palace Company by which the new Company will supply the first 400 H.P. required by exhibitors at the forthcoming Electrical Exhibition. A generating station is to be erected by Messrs. Gordon and Co. capable of supplying 400 H.P. to the Crystal Palace, and afterwards to supply electricity to 20,000 lamps. We must refer our readers to the prospectus for further particulars. The lists of applications opened on Monday last, and will close not later than 4 o'clock this day (Friday.)

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 693.—Vol. XXVII. FRIDAY, AUGUST 28, 1891. Price Fourpence.

NOTES.

The Cardiff meeting of the British Association will not prove of great interest to electricians, as the Papers read were not very numerous, and, on the whole, possessed no striking merit. The chief event was the discussion on electrical nomenclature in Section A.

Mr. Swinburne's Paper on the Causes of Variation of Clark's Standard Cells contained the result of a great amount of patient work. Before the Clark cell can be accepted as a practical standard, the effect on its electromotive force of a number of minor influences must be thoroughly investigated. The fact that Lord Rayleigh and Mr. Glazebrook have obtained for the cells made up by them electromotive forces which agree much nearer than one-tenth per cent. is not a sufficient recommendation of the cell as a standard. The cells were set up, and the measurements made at intervals of several years, but the construction was probably carried out on identical lines, and the chemicals obtained from the same source. Under these circumstances such close agreement is to be expected when exceptional skill is used. The crucial test lies in a comparison of cells made up with ordinary care from materials obtained from different places, and it is in this connection that Mr. Swinburne's Paper is so valuable, for it describes in detail the effect of a number of the smaller circumstances influencing the electromotive force.

On Tuesday, Prof. Carey Foster read the annual report of the Committee of Electrical Standards. This Committee is the oldest of all those which have, from time to time, been appointed by the British Association, and it has done much valuable work. An evidence of its importance has but recently been given by the selection, by the Board of Trade, of a Committee on Standards to a large extent composed of those physicists who have been most prominent in the analogous work carried out by the British Association. Naturally, the report this year referred more especially to matters in connection with the electrical standards which are shortly to be legalised.

Incidentally, a point of some practical importance was raised in the discussion. Prof. Viriamu Jones, of Cardiff, stated that he had the means at his disposal to accurately determine, in absolute measure, the value of small resistances of about $\frac{1}{1000}$th of an ohm, and suggested that such standards might prove useful for commercial purposes. As Mr. Preece stated, there is a growing demand for a means of measurement of very large currents, such as are used in metallurgy and other electrical applications. Neither dynamometers nor ammeters can be conveniently made for very heavy currents, and the shunt method of connecting a sensitive instrument to the terminals of a low resistance placed in series with the main circuit, is by far the best to employ. In such cases a knowledge of the resistances, together with the sensitiveness of the instrument for weak currents, is sufficient to determine the magnitude of the strong currents to be measured, and it appears very probable that a demand will arise for accurately certified resistances of the character suggested by Prof. Jones, now it is known where such standards may be obtained.

In opening the discussion on "Units and their Nomenclature," a full report of which we hope to give in our next issue, Dr. Lodge directed special attention to the need for giving names to two units, viz., the unit of self-induction and either the practical unit of magnetic line density (B), or the practical unit of lines of force. The relative claims of *secohm*, *quadrant*, and *henry*, for the former unit, have already been discussed in these columns, and we need not further refer to them except to say that the word *quadrant*, although recommended by the Paris Congress and adopted by the British Association two years ago, has found but little favour in this country; and that none of the speakers during the discussion urged its adoption. The word *secohm* aims at being self-explanatory, and has proved very convenient as a temporary unit. Dr. Lodge points out that, if it were adopted, the *secvolt* would be the natural name for the unit of induction, this being such that if the number of lines of force through a coil were equal to five secvolts, and were removed in one second, the average electromotive force generated would be five volts. The word *henry*, however, appears to have the greatest number of supporters in England and America. It keeps green the memory of a distinguished physicist, and is a word which has already come into general use.

It does not, however, appear so desirable to name the unit of self-induction as the unit of magnetic field. The self-induction of a coil or armature expresses its magnetic properties, but not in a form most convenient or intelligible to the engineer, whose conceptions are based upon areas, magnetic fields, currents, and numbers of turns, so that a combination of all these, such as is self-induction, detracts from simplicity.

Digitized by Google

Mr. Preece, who spoke immediately after the President, referred to the long efforts made by the Association to get the metrical system of units adopted in this and other countries, and very pertinently remarked that as the ohm, volt, ampere, and farad were to be legalised in the course of a few months, it was most desirable that no suggestions should be made tending to show that any doubt existed that these units were the best to have.

Prof. Stroud then proceeded to explain his "revolutionary" notions about units. On examination it appears regrettable that, when the practical system of units was originally adopted, the ohm and volt were chosen different multiples of the corresponding C.-G.-S. units. This was done in order that the unit of voltage should be about equal to that of an ordinary cell, and the unit of current of the same order of magnitude as the currents in common use at that time. The varied conditions of practice at the present day render these considerations of no account, and Prof. Stroud shows how the relation of the practical and the C.-G.-S. systems could be considerably simplified by one or two fundamental changes. It, however, does not appear to be worth while to make these alterations, as the great advantages of a metrical and inter-related system of units are secured without them, the exact power of 10 necessary to convert a unit from the C.-G.-S. to the practical system can very readily be found, and it is of but small importance that it has many different values, according to the unit chosen. As Mr. Swinburne pointed out, the enormous difficulties put in the way of practical men by making alterations in any established system of units are not properly appreciated. The advantages Prof. Stroud seeks for may be attained by altering either the absolute C.-G.-S. system, or the practical system of units. Both changes were suggested, but electrical engineers will be as unwilling to adopt the latter as scientists the former.

Mr. Geo. J. Stoney, who was one of the members of the original British Association Committee of 1874, pointed out that no consistent system of units could avoid including some of very inconvenient size. He had objected at the time to the introduction of the practical system in addition to the C.-G.-S. system, and had suggested, in preference, a consistent method of naming multiples and submultiples. There is much to be said for Mr. Stoney's views, the correctness of which is being demonstrated now that many other units besides the ampere, volt, and ohm are needed for practical purposes. It has several times been proposed to make the henry, the unit of self-induction, some submultiple of the secohm, on account of this unit being rather larger than is common in practice. It would, however, be a distinctly retrograde step to adopt any other value for the henry than 10^9 C.-G.-S. units, as this is the only value which can be used consistently with the other practical electrical units.

The discussion afterwards wandered on to the subject of dimensions, although the connection with nomenclature was by no means clear. Mr. Stoney pointed out a simple and useful way of expressing the nature of the various electrical quantities. Prof. Rücker explained his manner of describing the relation between electrostatic and electro-magnetic units, and Prof. Silvanus Thompson pointed out the desirability of distinguishing ordinary quantities from others in which the idea of direction was involved. Prof. A. Gray thought that the phrase electromotive force was unfortunate, but that it would cause much inconvenience to drop it. We thoroughly agree with him as to this expression, but the inconvenience of dropping it is not so great as he thinks. It is very rarely to be found in our editorial columns. The discussion was continued by Prof. Carey Foster, Mr. Blakesley, and Prof. J. Viriamu Jones, and, although it showed no signs of flagging, was brought to an end by some concluding remarks of the President.

The Paper of Mr. Preece on the London-Paris Telephone was of considerable interest, especially to the more popular part of the audience, but it did not contain very much information which has not already been given by the author elsewhere. It appears that the quality of the sound transmitted does not depend much upon the instruments employed, as all kinds and makes of transmitters and receivers have been used with about equally good results. To this, however, there is one curious exception. Microphone transmitters are found to give much purer sounds than magneto-transmitters, and Mr. Preece attributes the difference to the fact that with the former the current variations are not nearly so sinuous as with the latter.

The Committee appointed to study the phenomena of the discharge of electricity from points presented a brief report. The investigation here referred to originated in the work of Dr. Lodge in connection with the dissipation of fog, and many will regret that the research, which at one time promised to successfully solve an important practical problem, seems now to have resolved itself into the explanation of a number of interesting but rather abstruse matters. It was found at an early stage of the inquiry that charged points only dissipated electricity easily when placed in the neighbourhood of an opposing point or plate, and the behaviour of isolated points had to be thoroughly investigated before proceeding further. The work has been mainly carried out by Mr. A. P. Chattock, who presented to the meeting a rather lengthy Paper on the Electrification of Needle Points in Air.

After a considerable delay, for which no reasons have been suggested, the Electric Welding Company have issued their prospectus, and invite subscriptions for one-third of their capital, which is fixed at nearly half-a-million. It was expected that the promoters would have most appropriately struck the iron while it was hot, soon after the brilliant display of the process in Great George-street. The prospectus contains no new information of any importance, nor does it suggest on what scale the process will warrant the expenditure of capital in laying down a powerful engine and dynamo, besides the expensive welding machines, in place of an ordinary brick forge, a fan, and the simple tools used by the smith. We fear that the system

Digitized by Google

of a royalty on each weld made will be very repugnant to English engineers, and while the prospectus says "the royalties are fixed at a very low rate," as though to induce *manufacturers* to adopt the system, it is admitted, for the encouragement of *investors*, that "in the aggregate they are expected to amount to a very large sum." It might have been supposed that after all that we have heard about this process in America, and the period that has elapsed since it was first pushed, that more than one hundred machines would have been already in use in the United States, but this is the figure given in the prospectus, and we are not informed if all of these have passed beyond the stage of experimental or tentative use. It is very obvious to any engineers who have watched the progress of electric welding that it is much better adapted to the wholesale rushing style of American manufacture than to the deliberate and ever-varying work which is done with us; and yet it is expected that in this country one hundred machines will "be got into use the first year" and one hundred and fifty further machines in the second year. Prof. THOMSON's machines are, as every one will admit, most ingenious and useful devices for special purposes, and their value is greatest when they are designed for and restricted to continual work on one job such as welding ends on boiler stays. Remembering that the patents cannot cover the general principle, we fear that the proposed mode of introducing electric welding into this country will not play so great a part in our commerce and manufactures as is suggested by this prospectus.

BY the death of Mr. RAIKES the Government has lost one of its ablest supporters, and the Post Office a much-respected chief. From the day of his appointment as Postmaster-General, in 1886, Mr. RAIKES not only assumed the headship of a great department, but actually directed and controlled it. Nothing was too small or too great for his conscientious industry to take in hand, or for his undaunted spirit to carry through. His loss will be greatly felt in every branch of the service, and if his successor has a lighter task before him than the one undertaken by his predecessor, it will be because the chief difficulties have been overcome, and the schemes of reform well nigh completed. For the *employés* of the Post Office Mr. RAIKES worked most strenuously, and succeeded in placing them on a footing which leaves no reasonable ground for discontent. It is the usual lot of Postmaster-Generals to be much abused; and Mr. RAIKES had, perhaps, more than his fair share of newspaper criticism. But when his achievements are candidly reviewed, it will be found that no man deserved public censure less. Perhaps no one felt it more; for when it is said that he died of overwork, we cannot dismiss from our thoughts the suspicion that over-worry may have had something to do with his untimely end.

THE correspondence which has been going on in the *Standard* relating to village industries and postal facilities may serve a useful purpose, if only to suggest the possibilities of rural industry. Long before such possibilities are realised, however, there will be no lack of postal and telegraphic facilities. At present, so far as can be gathered from the complainants' letters, there is no case of tangible hardship, except perhaps to individuals who furnish high sounding pretexts for their personal demands. That this is the literal truth is pretty evident from the indignant protests called forth against the guarantee required by the Post Office before extending wires to places where the telegraph business likely to be done would not be remunerative. If the applicants hesitate to guarantee so small a sum as is asked for, the inference is that nobody wants the telegraph but themselves. Less than 20 messages a week would cover the guarantee. No reasonable being can expect an expensive service to be established without evidence, to that extent at least, that the service is needed. At all events, where village industries are concerned—if any such there be—we may be sure they will have no difficulty in finding the money. Meantime it ought to be better known than it generally is that a telegram can always be *posted* to the nearest telegraph office, often reaching there in a few hours, and thus beating the through post by perhaps half-a-day.

Milan.—The Milan Central Station is now supplying about 22,000 glow lamps and 852 arcs.

Whitechapel District Board.—At the last meeting of this Board the Clerk was instructed to take the necessary steps to have a Provisional Order prepared and presented.

Electric Traction in Rome.—An application has been laid before the Town Council for a concession for working four new tramway lines in Rome by electricity, by means of an underground conductor.

Shrewsbury.—At the last meeting of the Town Council the application of the Shropshire Electric Light and Power Company for consent to their application for a Provisional Order was considered and the application was granted.

Arco.—The electric lighting of Arco, in the Tyrol, has been secured by the Vienna firm Kremenezky, Mayer and Co. Water-power to the extent of 200 H.P. will be used. The street lighitng is to be effected by glow lamps at 150 volts.

The Patent Office.—Mr. Leng, M.P., whose able speech on the subject of Patent Office administration we reprinted in our issue of July 17th, is engaged in getting up a petition to be presented to the Board of Trade praying for an alteration in the present scale of fees, &c.

City of London Electric Lighting Company.—We learn that the Board of Trade have given their final consent to the transfer to this Company of the Provisional Orders granted to the Brush Electrical Engineering Company and the Laing, Wharton, and Down Construction Syndicate.

Hamburg.—Tenders for the supply of electric energy in Hamburg will be received up to October 10th. The conditions under which the concession will be granted may be obtained on payment of five marks, from the Secretary to the Finance Committee (Rathans I. Stock, Zimmer No. 34).

Caledonian Telephone Company.—Under this name there has just been formed in Glasgow a Company which has as its aim the development of the private business in running telephone lines, and supplying French instruments, which was recently started by Mr. A. Erskine Muirhead, of that city.

Paris.—An inquiry, says our Paris correspondent, has been opened at the Préfecture de la Seine with regard to the proposed tubular electric railway, running across Paris from the Bois de Boulogne to the Bois de Vincennes. At present a railway journey between these two points involves a long *détour*, and takes an hour and a-half.

Church Lighting.—The old City church of St. Nicholas Cole Abbey is to be lighted by electricity. The rector says he has taken this step to relieve the congregation of "the insufferable atmosphere of the gas, which put the organ out of tune and the people out of temper, spoiled the colour on the walls and ceiling, and did harm to the health of not a few of us."

Digitized by Google

Kingstown Town Commissioners.—At the last meeting of this body the following motion was passed unanimously:—"That the Town Clerk be instructed to advertise for tenders for lighting the township for one or three years with either electric light or gas. Tenders to be considered at the first meeting in October. The Town Clerk to prepare a detailed statement of the cost of lighting the township during recent years."

Glasgow.—The Glasgow Electric Light Committee yesterday agreed to recommend the appointment of Mr. Wm. Arnot, who is at present Electrical Inspector to the London County Council, as Electrical Engineer under the Corporation. Mr. Arnot has, we understand, had considerable experience in both high and low-tension systems of electric lighting work in London and Plymouth, as well as at the Grosvenor Gallery Station. He had for some time the management of the engineering department of Messrs. Latimer Clark, Muirhead and Co.'s works.

Mexican Government Telegraph Receipts.—The growth of telegraphic traffic in Mexico, through the development of the country, is steadily increasing the revenue receipts under that head. The total revenue under the head of Telegraphs is still small, but it is growing at a satisfactory rate, the increase during the past three years having been nearly 100 per cent. The following comparison is taken from the official revenue returns for the last four fiscal years:—

1886-7.	1887-8.	1888-9.	1889-90.
$197,498	$275,856	$329,493	$388,926

British Association.—According to the *Times*, soon after the conclusion of Prof. Silvanus Thompson's popular lecture on "Electricity in Mining," given on Wednesday evening in the Park Hall, Cardiff, an accident occurred. Prof. Thompson had on the platform a coalcutter, which was set in motion after the lecture. A man got upon the platform, without permission, and put his right foot over the revolving rod. The projecting spikes instantly cut into his leg just above the ankle, and broke the bone. He was laid hold of and dragged away before he was further injured.

Edisonia.—Under the title of "Edisonia" the *Electrical Engineer*, of New York, publishes, with its issue of August 12, a survey of the Edison Light and Power Industries, in the shape of an elaborate special supplement of some twenty pages. The illustrations, typography, and general get-up of "Edisonia" are of the excellent description characteristic of American work in this direction; and, had the text contained more "esoteric details," and fewer quotations from Charlotte Brontë, Tennyson, Dryden and Shelley, the supplement would have been as interesting as it undoubtedly is artistic.

The Electrical Utilisation of Water-power in Bavaria.—A company has been formed in Lindau under the name of the Elektricitätswerk der Argau, for the purpose of supplying Lindau, Langenargen, Friedrichshafen Tettnang, Ravensburg, Weingarten, and Wangen, with electric light and power. At a meeting recently held, Herr Huber, of the Maschinen Fabrik Oerlikon, recommended the adoption of the rotary current. About 3,000 H.P. will be available for distribution. It is estimated that the yearly charge for 1 H.P. will not exceed £6 or £7, and that lamps will cost about £1 or 25s. per annum.

The Lauffen-Frankfort Transmission Plant.—Our Frankfort correspondent telegraphs that the Lauffen-Frankfort transmission is expected to be in regular operation at the end of the present week. The line is finished and tests are being made. A number of glow-lamps, in series, are set up on a frame to show the reality of the pressure at which the current is transmitted (20,000—25,000 volts). The posts supporting the line are all adorned with skulls and crossbones, and have the warning notice, "Don't touch," painted on them. On Wednesday motors were driven by the current from Lauffen.

Sheffield Technical School.—We have received the 1891-92 prospectus of this Institution. Although, of course, the greatest attention is devoted to the metallurgical department, other studies are not neglected. The total number of students on the registers during the past session was 518, as against 197 for 1889-90. The following extracts from the Principal's report will show that those responsible are imbued with the true spirit of technical education:—"It has been the earnest desire and aim of the promotors of the School, from the beginning, to provide a school for the scientific study of steel, which should be worthy of this great centre of the steel industry. This object is now an accomplished fact, and Sheffield may be congratulated on possessing the most complete School of Metallurgy in existence. . . . The applications for places in the metallurgical laboratories are in excess of the accommodation, and *the students in this department are chiefly those actually engaged in some branch of the steel trade.*"

Brighton.—At the last meeting of the Town Council it was announced that the supply of electricity would commence not later than September 15th. Considerable discussion arose with regard to the tender of Messrs. Sharp and Kent for wiring and fitting the central station for electric light. The Lighting Committee reported that, on August 4th, they had accepted the tender of Messrs. Sharp and Kent to perform the work in accordance with the specification prepared by Mr. Shoolbred for the sum of £189. 15s.; but that, at a further meeting held on August 10th, Mr. Shoolbred reported that Messrs. Sharp and Kent had withdrawn their tender of £189. 15s., and had made an amended offer to do the work at the price of £204. 15s., and that it was resolved to accept the amended tender. Councillor Nell said he thought it a bad example to allow a tender to be withdrawn after acceptance, and a higher price added, and Alderman Sendall moved the exception of the proceedings. The exception was then put and carried.

Cable and Land Line Interruptions and Repairs.—

Bridges Operated by Electric Power.—One of the latest American applications of electric power is the operation of swing-bridges. In Chicago a bridge, weighing about 800 tons, 240ft. long, and 59ft. broad, is worked in this manner. Heretofore power had been obtained from an engine and boiler perched 20ft. above the roadway of the bridge, between the main trusses. When these and the heavy gearing connected with the steam mechanism are discarded, it is estimated, says the *Western Electrician*, that the saving in weight will amount to about 40 tons. The current is furnished from the station of the Chicago Arc Light and Power Company. The motor has been thoroughly tested under every circumstance, and has proved satisfactory. A similar draw-bridge is the Grand Avenue Bridge in Milwaukee. This is 180ft. long and 35ft. wide, and weighs 200 tons. Before the introduction of electricity this bridge was operated by hand, and it could not be swung to allow a vessel to pass in less than five minutes. Now one man can control the operation of it with perfect ease, and at the same time make a quarter turn in 30 seconds. The equipment of both bridges, both mechanical and electrical, was carried out by the Thomson-Houston Company. The Milwaukee bridge has worked satisfactorily for two months.

Some Lately Manufactured Telephone Cables.—In the *Electrical World* of August 15th, Mr. Herbert Laws Webb has some corrections to make in an article on this subject by Mr. Perrine, which appeared in our New York contemporary, and was reproduced in our last issue. "When we come," Mr. Webb remarks, "to the speaking limit of the Roebling cable, there is a far more startling difference between Mr. Perrine's figures and the true ones. The cause of the error is that Mr. Perrine

Digitized by Google

has taken the K R *per mile*, instead of making it the product of the *total* resistance into the *total* capacity of the cable. It is a very simple error, and one that has often been made before, always, of course, with the same wonderful results that are obtained in this case. Taking the New York cable, Mr. Perrine finds that according to Jacques' formula we could speak 736 miles with a Blake transmitter, and 1,650 miles with a Hunnings. . . . Taking the capacity at ·081 microfarad per mile, and the resistance at 34·95 ohms, the speaking limit would be as follows:—

Jacques' limit for Blake transmitter...KR = 2,000 27 miles.
" " " Hunnings " ...KR = 4,500 40 "
Preece's " " underground work KR = 8,000 54·2 "

Such figures as 27 miles, 40 miles, and even 54·2 miles, look very insignificant beside such considerable distances as 736 miles and 1,650 miles."

The Electrical Trades' Section and the Frankfort Exhibition.—We are asked to state that the Sub-Committee recommends that gentlemen joining the party in connection with the Electrical Trades' Section of the London Chamber of Commerce should travel *viâ* Dover and Ostend, leaving Holborn Viaduct Station by the train at 10 o'clock, a.m., on Saturday, the 5th of September. Each member of the party should provide himself with the necessary travelling ticket, and it is recommended that such tickets be obtained through Messrs. Cook and Son, Ludgate-circus, E.C., the fare being, *viâ* Dover and Ostend, £5. 16s., first class return, available for 30 days. The ticket should be taken on or before the 2nd of September, and, in the event of this being done, Messrs. Cook and Son will engage reserved railway carriages between London and Frankfort, and members are requested to specify that they belong to the Electrical Trades Section party. Members are further notified that ladies may be included in the party. With regard to hotel accommodation the Sub Committee could not well engage definitely sufficient rooms beforehand for the entire party, but the Committee suggests to members to adhere to the following suggestions, in which case they will, no doubt, be suited for rooms. They can either buy coupons for rooms and dinners through Messrs. Cook and Son, for the Swan Hotel, Frankfort, and if such coupons are taken at the same time as the ticket Messrs. Cook will take steps to reserve sufficient and good accommodation. Or members of the party can secure rooms at the Britannia Hotel or Hotel Romkscher Kaiser, if they write to the proprietors about a week beforehand, mentioning that they belong to the Electrical Trades' Section party. The Committee is in communication with the President of the Electro-Technical Society of Frankfort with respect to tickets for the various events in connection with the Exhibition and Congress, and gentlemen will be advised, if necessary, as to what special arrangements can be made in this respect. Any further information that may be required can be had on applying to the Chamber of Commerce.

The Telegraphs of Nicaragua.—The United States Consul at Managua, writing with regard to the telegraphic service of Nicaragua, says:—"The year 1862 saw the dawn of the telegraph system in the Republic of Nicaragua. The first line was constructed by the Transit Company between the ports of San Juan del Sur, on the Pacific coast, and Virgin Bay, on Lake Nicaragua, and was 15 miles in length. The line was afterwards abandoned by the Transit Company, and, so far as is known, nothing was done towards the system until the year 1876. In this year the Nicaraguan Government employed a Costa Rican to commence the construction of a national line. During this year 190 miles of telegraph were erected, and offices opened for the transaction of business in the principal cities. The line during the year 1879 was extended to Jinotepe, a distance of 12 miles, and communication established between Somotillo and Choluteca. On June 24, 1880, the port of San Juan del Sur was connected with Liberia (Costa Rica), uniting the lines on the frontiers of the two Republics. The line was reorganised in the latter part of the year 1880. An extension was made into the gold-mining district of Chontales. The frontiers of Nicaragua and Honduras were united, in 1882, by the construction of a line between Ocotal and Paraiso. It being found that the business of the country could not be properly transacted by the line then in operation, the Government erected a second line between Granada, Masaya, and Leon, these being the principal business centres of the Republic. During the year 1882 an office was opened at San Juan del Sur by the Submarine Cable Company. The year 1886 witnessed the introduction of the telephone system between Acoyapa and San Obaldo, the length of the line being 15 miles. As the country was steadily growing in population and commerce, it became necessary to extend the telegraph system, and, in 1887, the line was extended to Managua, Masaya, and Granada, a distance of 33 miles. Another line was added, in 1888, between Mometombo and Leon. The total number of miles of telegraph lines erected during the year 1889 was 334; telephone lines built for same period were 56 miles. Since 1888, 250 miles have been built, at a cost of $38,434·80. The line has also been prolonged from San Carlos, at the junction of Lake Nicaragua and the San Juan River, to Castillo, on the same river, a distance of 45 miles. This extension was made necessary on account of the location of a Custom House at the latter point. Here the National Line joins that of the Canal Construction Company, which extends to San Juan del Norte, on the Atlantic coast, a distance of 95 miles, and has seven offices on the route.

Obituary.—Mr. Edward Gilbert, whose death was recently recorded in the Dundee papers, was long and intimately identified with telegraph work abroad as well as at home. A native of Oxford, he was in early life in the service of the Electric and International Telegraph Company, snd by diligence and perseverance he rose in the service until he was appointed superintendent for the northern district, his headquarters being the city of Aberdeen. While he was in this employment he served under Mr. Cromwell F. Varley and Mr. W. R. Culley. In 1864 Mr. Gilbert was offered and he accepted the position of Telegraph Superintendent of the Scottish North-Eastern Railway Company, and the district over which he had control extended from Aberdeen to Perth and Dundee, and covered a large portion of the ground included in the system of the Electric Telegraph Company. His new position was, therefore, a somewhat difficult and delicate one, and he was often called upon to deal with matters somewhat antagonistic to his old employers, but by his tact and ability he managed to settle intricate questions without the least friction. When the Scottish North-Eastern Company was, in 1866, amalgamated with the Caledonian Company, Mr. Gilbert was continued in his old position, but in the following year he was induced to transfer his services to the North British Railway Company, a change which led to his removal to Edinburgh; and while resident there he distinguished himself by the manner in which he carried on the work of his department. When, in 1868, negotiations were opened between the Government and the various railway companies for the acquisition of the telegraph system by the State, Mr. Gilbert was requested to take a prominent part on behalf of the North British Railway Company, and the agreement which he eventually drew up on behalf of that company was the basis of all the settlements which followed. The agreements then made are still in force, and probably the most important feature of them for the railway companies is the privilege which they have of sending messages over the Government wires free of charge. In 1874 Mr. Gilbert resigned his appointment with the North British Railway Company, and accepted the position of Superintendent-in-Chief of Telegraphs for the Japanese Government. While in Japan he re-organised the telegraph system of that country, and during the five years that he remained there he was instrumental in putting the service on a very satisfactory basis. Returning to this country, towards the end of 1879, Mr. Gilbert was offered the post of Manager and Secretary of the Dundee and Arbroath Joint Railway. He continued in that post up till his death.—We regret to record the death of Sir Thomas Fairbairn, Bart., which occurred on the 12th instant, at his country seat, at Bishopstoke, near Southampton. Sir Thomas, who was born in Manchester, in 1822, was connected with the Associated Submarine Telegraph Companies. The funeral took place at Twyford, near Bishopstoke, on Tuesday, the 18th, and many of the deceased's friends and old associates were present.

ON THE ELECTRO-MAGNETIC THEORY OF THE ROTATION OF THE PLANE OF POLARISED LIGHT IN A MAGNETIC FIELD.*

BY PROF. A. GRAY, M.A.

Sir William Thomson has explained the turning of the plane of polarised light in a magnetic field by supposing the ether to have imbedded in it a large number of small gyrostats, having the undisturbed positions of their axes in the common direction of the magnetic force, and the propagation of the beam, and all rotating in the same sense. When, in consequence of the vibratory motion, each gyrostat has its axis of rotation displaced from this direction it reacts on the surrounding medium with transverse force at right angles to the plane through the axis of rotation and the direction of motion.

By compounding this stress with the elastic forces of displacement of the ether, differential equations of motion are obtained which are of precisely the form necessary to account for the difference in rate of propagation of the two circularly polarised rays constituting the plane polarised ray.

The equations thus found are of the form

$$\rho\frac{\delta^2\xi}{\delta t^2} = n\frac{\delta^2\xi}{\delta z^2} + c\rho\frac{\delta^3\eta}{\delta t\,\delta z^2}$$

$$\rho\frac{\delta^2\eta}{\delta t^2} = n\frac{\delta^2\eta}{\delta z^2} - c\rho\frac{\delta^3\xi}{\delta t\,\delta z^2}$$

where ξ, η, denote component displacements of a portion of ether in two rectangular directions perpendicular to that of z taken as the direction of propagation, p, the density of the ether, in its proper elastic constant, and c a constant depending in the rotating matter.

It is suggested by the gyrostatic investigation that it ought to be possible to explain the magneto-optic rotation on the electro-magnetic theory of light, as a consequence of the existence of the small magnets which are supposed imbedded in the medium with their axes in the direction of propagation of the ray, and, therefore, producing the magnetisation of the medium on that direction.

In consequence of the motions of the ether, the directions of the chains of magnetised molecules, which are supposed to exist along the direction of magnetisation (here taken as axis of z), in the undisturbed state of the medium, are continually undergoing change at every point, and thus the direction of the axial magnetic force along each chain also undergoes alteration. It is obvious that if the displacements be everywhere small the actual magnitude of this force will sustain only a comparatively small percentage of alteration, but that each such small change of direction will produce a component magnetic force in each of the two directions at right angles to the axis. The calling into existence of these components will produce corresponding electromotive forces tending to increase or diminish the electric displacement.

The electromotive force in the direction of y is given in Maxwell's notation by

$$Q = -\frac{dG}{dt} - \frac{\delta\psi}{\delta y}$$

where dG/dt stands for the total time-rate of change of G, the component of vector potential in the direction of y, and δ denotes partial differentiation. Also since H, the component along z, does not perceptibly vary along x, if the direction of propagation be as taken here along z, $-\delta G/\delta z$ denotes magnetic induction through unit of area in the plane of yz. Hence any part of the total time-rate of variation of $-\delta G/\delta z$ will denote the space-rate of variation, in the direction of z, of an electromotive force parallel to y, provided the time and space differentiations of the part are commutative. This result is to be borne in mind in what follows.

Now, if the displacement of the ether particles from the undisturbed positions be taken as parallel and proportional to the electric displacement, and C be the component of magnetisation of the substance in the direction of z due to the existence of the molecular magnets, then, considering the electric displacement f in the direction of x, the component magnetic force in the direction of x will be, approximately, $e\,C\,\delta f/\delta z$, and thus the magnetic induction through unit of area in the plane of yz is $\mu e C\,\delta f/\delta z$, where e is a coefficient of proportionality. The time-rate of variation of this is

$$\mu e C\frac{\delta}{\delta t}\times\frac{\delta f}{\delta z}$$

But we have by the equations of electric currents

$$\frac{\delta f}{\delta t} = \frac{1}{4\pi}\left(\frac{\delta\gamma}{\delta y} - \frac{\delta\beta}{\delta z}\right) = -\frac{1}{4\pi}\frac{\delta\beta}{\delta z}$$

since there is no conduction current.

Further, by the relation of magnetic force to vector potential, $\beta = (\delta F/\delta z)/\mu$, and therefore the last equation becomes

$$\frac{\delta f}{\delta t} = -\frac{1}{4\pi\mu}\frac{\delta^2 F}{\delta z^2}.$$

Now, since the differentiation of f with respect to t is partial only, we may use the substitution

$$\frac{\delta}{\delta z}\frac{\delta f}{\delta t} = \frac{\delta}{\delta t}\frac{\delta f}{\delta z}.$$

Hence differentiating $\delta f/\delta t$ with respect to z we find

$$\mu e C\frac{\delta}{\delta t}\frac{\delta f}{\delta z} = -\frac{e C\delta^3 F}{4\pi\delta z^3},$$

which gives an electromotive force in the direction of y of amount

$$-\frac{e C\delta^2 F}{4\pi\delta z^2},$$

since there can be no constant or arbitrary time function concerned. Hence we have, finally,

$$Q = -\frac{\delta G}{\delta t} - \frac{e C\delta^2 F}{4\pi\delta z^2} - \frac{\delta\psi}{\delta y}$$

and therefore

$$\frac{\delta Q}{\delta t} = -\frac{\delta^2 G}{\delta t^2} - \frac{e C\delta^3 F}{4\pi\delta t\,\delta z^2}.$$

But the displacement current in the direction of y is dg/dt, and this is $K/4\pi.\delta Q/\delta t$. Also by the equations of currents $\delta g/\delta t = -I/4\pi\mu\delta^2 G/\delta z^2$. Therefore we have the equation

$$\frac{K}{4\pi}\frac{\delta Q}{\delta t} = \frac{\delta g}{\delta t} = -\frac{1}{4\pi\mu}\frac{\delta^2 G}{\delta z^2},$$

which, used in the equation already found for $\delta Q/\delta t$, yields

$$\frac{\delta^2 G}{\delta t^2} = \frac{1}{K\mu}\frac{\delta^2 G}{\delta z^2} - \frac{e C\delta^3 F}{4\pi\delta t\,\delta z^2}.$$

Similarly for the other component in the case of circularly polarised light we find the equation,

$$\frac{\delta^2 F}{\delta t^2} = \frac{1}{K\mu}\frac{\delta^2 F}{\delta z^2} + \frac{e C\delta^3 G}{4\pi\delta t\,\delta z^2}.$$

These two equations are identical in form with those given by the gyrostatic theory, and, of course, lead to the same results; that is to say, the plane of polarisation of an electromagnetic beam would show a turning effect in a magnetised medium.

The fundamental assumption here made that f, g, h are proportional to the ether displacements seems a reasonable one, and is in accordance with the view generally held (but not yet, perhaps, proved) with respect to the electro-magnetic propagation of light. If the above theory be otherwise satisfactory, it gives some support to that view.

The theory given above has been suggested by a reference in M. Poincaré's "Théories de Maxwell," to a note by M. Potier, in his French translation of Maxwell's Electricity, in which a theory apparently of this nature is given. I have not seen M. Potier's note, and it is possible that it has completely anticipated the present Paper.

* Abstract of a Paper read before the British Association, in Section A, Cardiff, August, 1891.

THE FRANKFORT EXHIBITION.—VIII.

(FROM OUR SPECIAL CORRESPONDENT.)

In respect of number and importance of their exhibits, Messrs. Siemens and Halske are certainly the foremost in the Exhibition; they occupy a large space on the right of the Machinery Hall and have made their exhibits here, as elsewhere in the Exhibition, thoroughly representative of the work of the firm. We give below an illustration of their large continuous-current machine, and the steam-engine to which it is coupled. It is by far the largest direct-current dynamo yet constructed. The armature has an outer diameter of 9ft. 10in., while the stellate magnet has an outer diameter of 8ft. 11in. The machine is built for a full load of 900 H.P., at 100 revolutions. In the Exhibition, however, it is coupled direct to a 600 H.P. engine by Kuhn, which runs at 75 revolutions. The stellate magnet is bolted to the bed-plate of the steam-engine, its other support being that for the bearings of the armature. The machine is 10-poled, and has 10 sets of brushes. As will be seen from the illustration the brushes are in direct contact with the armature itself. The chief advantages of this arrangement are the comparative ease with which the armature can be examined, faults detected, and the rapidity and ease of repair. The brushes are in sets of three. In Darmstadt, where there are two 100 H.P. interior-pole machines by this firm in operation at the central station, the brushes, which are of the same description as those employed here, have not yet been renewed, although two years in use. The brush-holders are constructed so that each individual brush can be adjusted independently when the machine is running, while all the brushes may be simultaneously shifted or lifted by the device shown in detail in Fig. 2. The insulation of the armature wire not bared to the brushes is simply thin paraffined fibre. The machine charges a battery of 168 Tudor accumulators, having a capacity of 540 H.P.H., and also drives two electric cars shown by the firm; for this latter purpose the current is transformed up to 300 volts by a continuous-current transformer.

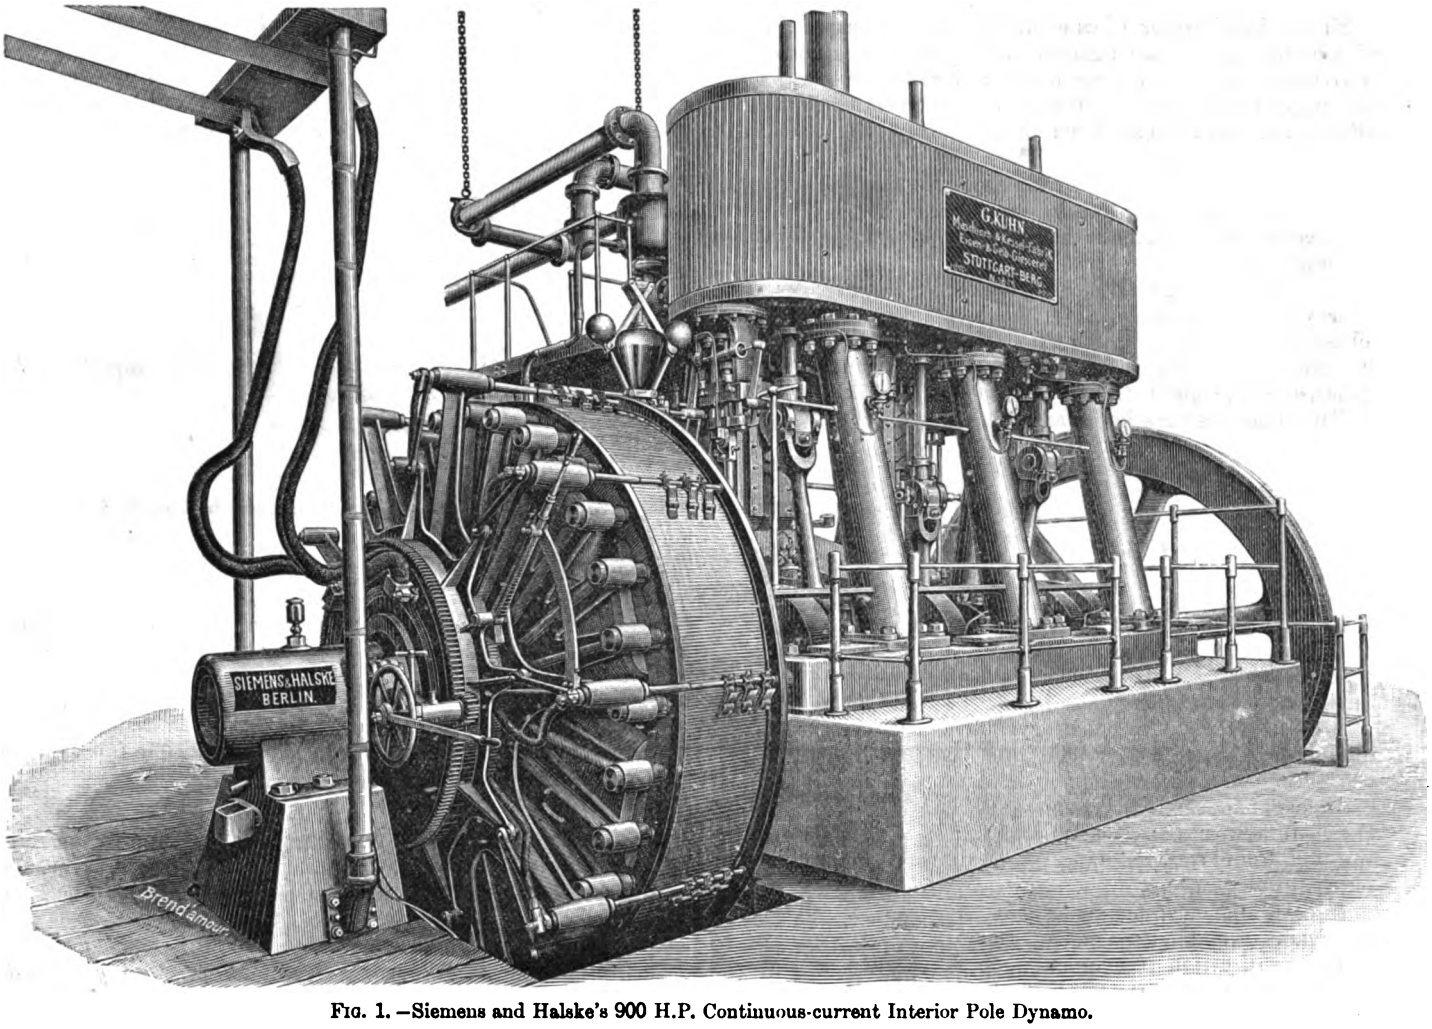

FIG. 1.—Siemens and Halske's 900 H.P. Continuous-current Interior Pole Dynamo.

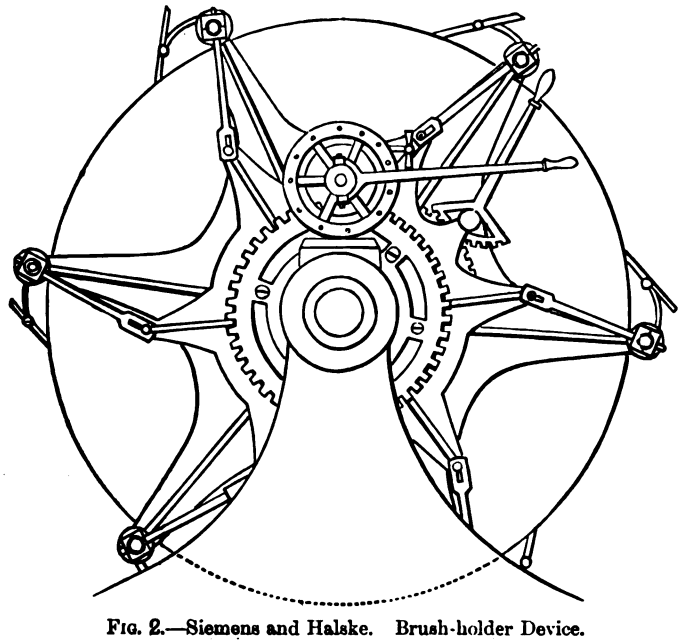

FIG. 2.—Siemens and Halske. Brush-holder Device.

The steam-engine to which the dynamo is coupled is by G. Kuhn, of Stuttgart-Berg. It is a triple-expansion condensing engine; the cylinder diameters are 1ft. 7½in., 2ft. 4in., and 3ft. 11in., and the piston stroke is 2ft. The steam pressure is from 150lb. to 180lb. per square inch. The engine was designed for an output of 600 H.P. when running at 120 revolutions, 500 H.P. at 100 revolutions, 400 H.P. at 80 revolutions. The high, medium, and low pressure cylinders are provided with steam jackets.

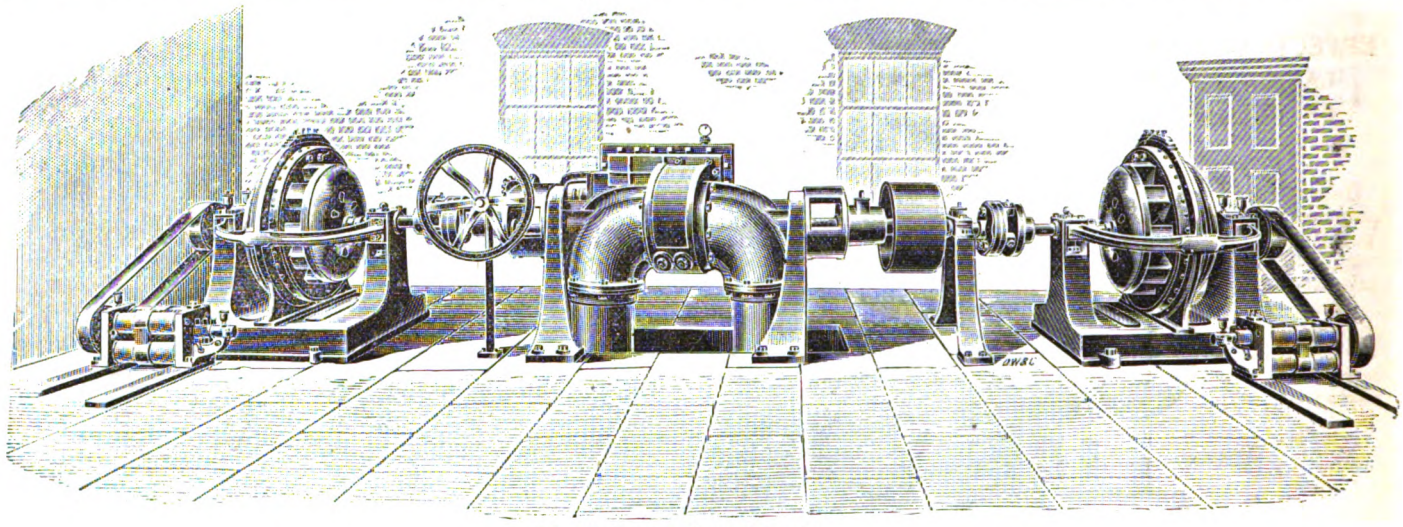
THE LYNMOUTH CENTRAL STATION.

Water-power stations are so few and far between in this country that a few particulars with regard to the small but interesting installation at Lynmouth, North Devon, may be of interest. The Lynmouth station has now been for some time in successful operation, the power being obtained from the River Lyn. The water of the River Lyn is diverted into an open conduit and thence into an iron pipe, 30in. in diameter and 1,700ft. in length, the available fall of water being 95ft. This fall of water is conducted to a 14in. turbine, capable of yielding 200 H.P. The horizontal shaft of the turbine is coupled direct to two Mordey alternators of the 37-unit size, running at 650 revolutions per minute. The exciting current is furnished from two small direct-current Victoria machines belted on to the shafts of the alternators (*see* Fig.) The electric lighting station is a small stone building on the bank of the East Lyn, the water being returned to the river when it has done its work. The current is supplied from the alternators at a pressure of 2,000 volts, partly by underground and partly by overhead mains. Each of the 37-unit alternators employed is capable of maintaining 1,200 or 1,300 8 c.p. lamps, all burning at one time.



The Lynmouth Central Station.

THE ANDREWS PENDANT SWITCH.

In reply to an inquiry which appeared on p. 431 of our last issue, Messrs. J. D. F. Andrews and Co., of Parliament-street, have sent us the following particulars of a switch which they think fulfils the requirements of our correspondent, who wanted "a reliable pendant switch composed solely of earthenware or other incombustible and non-hygroscopic material, with the necessary metal parts."

In outward appearance Messrs. Andrews's switch resembles a gas tap rather than an electric switch. The handle may be turned either way to make or break the circuit, the current being on when the tap is parallel with the centre line, and off when the tap stands at right angles. The internal construction is shown in Figs. 1 and 2. The contacts *c c* (Fig. 1) are insulated from the case by a new insulating stone called "alabite," which is moulded into position in the box with suitable dies under pressure, the contacts being fixed in the composition in one operation. The contacts *c c* are the terminals of the break in the circuit to be closed by the switch, and they are bridged by a disc, *d* (Fig. 2), which is actuated by the cam mechanism *a*. By turning the tap the pin *p* rises on the cam, forcing the disc on to the contacts, and is retained in that position under pressure by means of the spring *s*. The contact disc is insulated from the cam by a mica washer. The spring *b* throws the disc out of contact with a snap when the handle is turned to off.

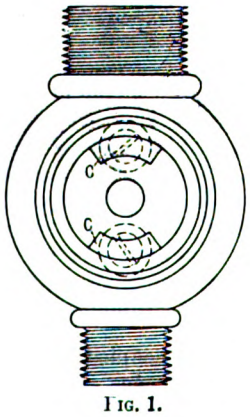


Fig. 1.

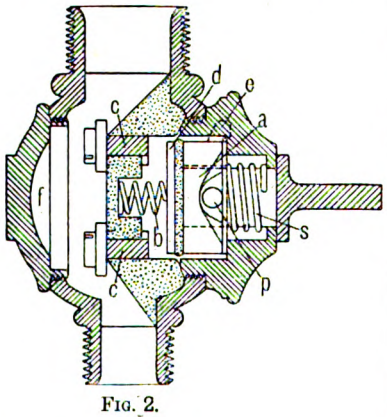

Fig. 2.

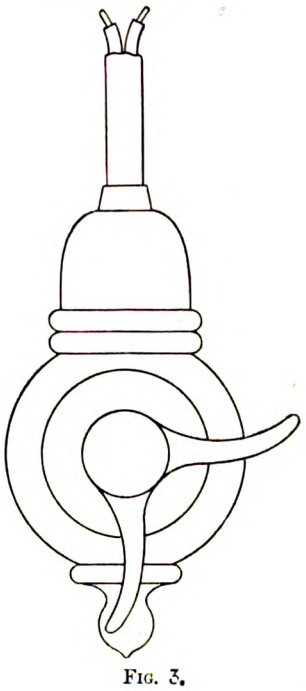

Fig. 3.

The sharpness of the break of the circuit is quite independent of the person operating, there being wide freedom in the slot *e* in which the guiding pin of the cam works. The connections of the wires are made by two screws, one to each contact at the back, which are got at by removing a cover, *f*. To enable

Digitized by Google

the switch to be easily turned with one hand when in connection with a light flexible cord, a form of handle is made, as shown in Fig. 3, which is worked by resting the thumb on the bottom knob and turning the handle with the first finger. This form of switch is intended to be used separate from the lamp attached to a flexible cord. The switch is also made in one piece with a bayonet socket lamp holder. The sample which has been sent to us is intended for use with concentric conductors.

A practical test was recently made with one of these switches. The handle was connected to the works shaft with a 75 volt lamp in circuit and the current made and broken 36,000 times. No detrimental wear was visible.

EFFECTS OF HIGH TEMPERATURES UPON THE INSULATION RESISTANCE AND INDUCTIVE CAPACITY OF VULCANISED INDIA-RUBBER.*

BY WILLIAM MAVER, JUN.

In some of the streets of New York City an abnormally high temperature exists under ground, caused by defective pipes of the New York Steam Company. In certain ducts and manholes of the electrical subways in the locality heated by the steam pipes, the temperature has been found to range at times from 110°F. to 200°F.

To ascertain the effect the writer undertook a series of tests, the results of which are shown in the accompanying diagram. Tests were also made at the same time to ascertain the effect of high temperatures upon the inductive capacity of vulcanised india-rubber, the results of which are also shown.

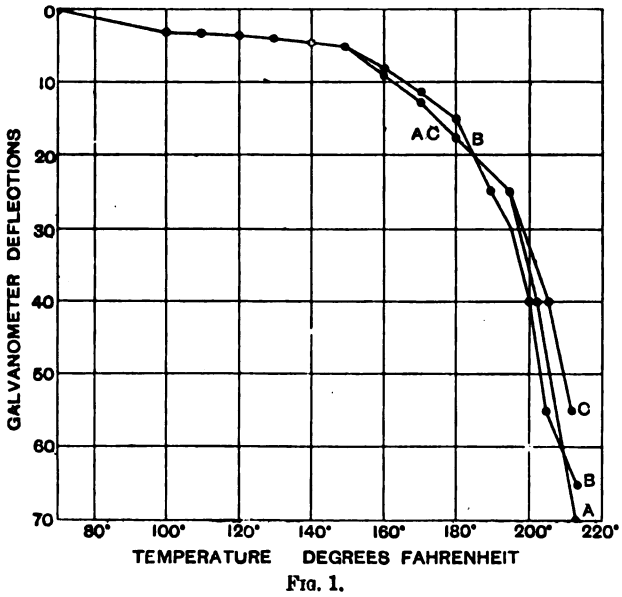

Fig. 1.

The cables tested were three in number, A, B, C, in the diagram, each 100ft. in length. The cables originally belonged to one piece, The conductor was ·097in. in diameter. The outside diameter of the insulating material was ·350in., approximately $\frac{11}{32}$; hence the thickness of the insulating wall was ·126in.

Cable A was unbraided and not lead covered.
Cable B was unbraided and lead covered.
Cable C was braided and lead covered.

This arrangement of the cables was chosen purposely to learn the effect, if any, of such coverings in diminishing the effects due to high temperatures.

A Thomson reflecting galvanometer was used. The readings for the capacity tests, in each case, taken at "charge"; those for the insulation resistance after one minute's electrification, that is, one minute after the depression of the charging key. Preliminary tests of the cables had shown the insulation resistance to be 1,500 megohms per mile at 70°F.

The working constant of the galvanometer at the time of tests, was 35,000 megohms. Hence (Fig. 1) it will be seen, for example that the total insulation resistance of cable A fell from 7,000 megohms at 150°F. to 500 megohms at 212°F.; that of cable B, from 7,000 megohms at 150°F. to 538 megohms at 212°F.; that of cable C, from 7,000 megohms at 150°F. to 636 megohms at 212°F. Calculated per mile, the insulation resistance of A would be at 150°F., 132·5 megohms; at 212°F., 9·5 megohms; that of B at 150°F., 132 5 megohms; at 212°F., 10·02 megohms; of that of C at 150°F., 132·5 megohms; at 212°F., 12·4 megohms. It is, however, unlikely that such high temperatures as these will ever be met with over a continuous extent of territory amounting to one mile. In practice such temperatures have not hitherto been found to extend continuously for more than 50 or 100ft. Hence, assuming the normal insulation resistance of a cable practically similar to those tested to be as stated, 1,500 megohms per mile, it may be observed that even with a 100ft. section of the cable exposed to a temperature of 212°F., the cable, as a whole, would show an insulation resistance of, approximately, 450 megohms per mile. From the results of the tests it may also be seen that any one foot of the cable would possess at 212°F. an insulation resistance of, approximately, 63,000 megohms, while any one inch of the same cable would possess an insulation resistance of 756,000 megohms at the same temperature.

Concerning the effect of ordinary changes of temperature on the electrostatic capacity of conductors, Kempe states: "The exact

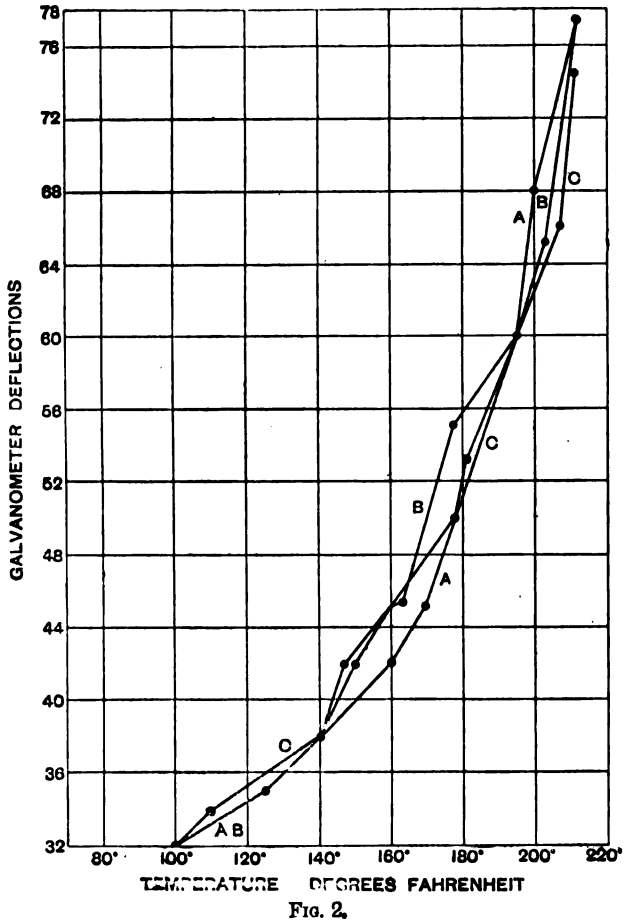

Fig. 2.

effect has not, it is believed, been yet determined or published." The capacity tests of the cables in question, as will be seen by reference to the "capacity" curve in Figure 2, indicate a marked increase in the inductive capacity of the insulating material between the temperatures of 100°F. and 212°F., namely, an increase of nearly 140 per cent. The capacity of C at the boiling point was somewhat less than that of A and B; which result, it is assumed, indicates that the cotton braiding acted, measurably, as a non-conductor of heat. It may be noticed also that, in both the insulation and capacity tests, the curves for C indicate a more uniform effect due to the increasing temperature.

The foregoing tests, which extended over a period of six hours, were made while the cables were immersed in water in a vat. The temperature of the water was gradually raised to the boiling point. The final tests were made after the cables had been subjected to the boiling temperature for over one hour. Immediately after the final tests the temperature of the water was reduced to the normal, when it was found that the insulation resistance and capacity of the cables were again practically normal.

It may be of interest to note that for over one year "high" potential electric light circuits have been successfully operated through ducts in the "heated districts" of New York City, and without any perceptible deterioration in the insulation resistance of the cables.

* From the *Electrical Engineer* of New York.

† We have divided Mr. Maver's single diagram into two separate ones with a view of making the curves more clear.

THE BRITISH ASSOCIATION.

The Cardiff meeting of the British Association has attracted fewer members than any other meeting of recent years, the associates and members being numerically but little more than half those attending the Newcastle meeting two years ago. Perhaps the falling off may be partially attributed to the change of date, which is earlier this year by nearly a month than is usually the case, but the steady decrease in numbers on the last three or four occasions indicates the necessity for some effort being made to revive public interest in the Association's proceedings. The social success of the meeting was unfortunately much impaired by the unfavourable state of the weather, and, to many, an attractive feature of these gatherings was lacking, owing to the marked absence of several of the more prominent leaders of electrical science.

The Presidential addresses were quite equal in interest and power to those of previous years. The very able address upon astronomical subjects, given by the President, Dr. HUGGINS, does not call for much remark here, as it is of only indirect interest to electricians. The inter-connection between electrical and other sciences is, however, exemplified in more than one part of the address, as, for instance, when the possible dependence of terrestrial magnetism on the sun is alluded to. In this connection it may be of interest to recall the fact that, in 1889, Prof. SCHUSTER showed that the diurnal variations of terrestrial magnetism had to be attributed to a cause external to the earth's surface, and there can be little doubt that the sun is in some way the source of them. Mr. FOSTER BROWN'S address to Section G on mining operations was noteworthy for the preference he declared in favour of the use of electrical plant, while Dr. LODGE'S address to Section A was remarkable for the boldness and originality of the suggestions made. It rarely falls to the lot of a President to have the opportunity of calling attention to an important advance science, and the great majority of Presidential addresses accordingly consist of little more than learned and dull summaries of old matter. Few people have the courage to enter upon highly controversial subjects before a scientific assembly, but Dr. LODGE is evidently one of these few. His views as to the extension of science in other directions than those already recognised are boldly expressed, but they are probably shared to some extent by the majority of people, while at the same time there is a strong and unreasonable prejudice against investigation in certain directions. It is the plain duty of physicists to investigate the forces of nature, and if certain unexplained forces exist, or are said to exist, the problems which Dr. LODGE indicate will one day have to be faced. The idea of a National Laboratory is more tangible, but its chance of life

Digitized by Google

seems but small. Apart from the great difficulty of endowment, the character of its work is rather vaguely defined. It would no doubt prove useful for experiments needing a long time to carry out, but it is difficult to forsee the theoretical or practical value of such work which not unfrequently ends in a negative result. It is also only sometimes true that "discoveries lie along the path of extreme accuracy." This is the case with mathematical subjects, such as certain branches of physics, and in astronomy, but not of the great majority of subjects.

We have alluded in another column to the principal Papers read, and the discussions following them. As regards the arrangements in general we can only emphasise the observations we made last year in reference to the meeting at Leeds. The Papers are far too numerous to be properly dealt with in the short time allowed for them, and the custom of carrying on the meetings for four hours without any interval results in a general thinning of the audience at lunch-time, which is necessarily most annoying to those whose Papers appear late on the programme. The audiences at Sections A and G are never large, and when they dwindle from 20 down to some half-a-dozen the situation simply becomes ridiculous. The adoption of a short luncheon interval would much improve this state of affairs, and the value of both Papers and discussions would be greatly enhanced if a limit was put to the number of Papers, and if these were set up in type and distributed previous to the meeting. Scientific Papers are difficult to follow when read, and it often happens, owing to obscureness of style, that the more valuable the Paper the less its merit is appreciated when heard for the first time. To criticise a Paper under these circumstances is next to impossible, and the barren nature of most of the discussions which take place at the British Association meetings is not to be surprised at.

When the subject of discussion is known in advance the result is quite different. Thus the joint meeting of Sections A and G, for the purpose of considering the nomenclature of the various electrical and mechanical units, is one which those present will remember for the great interest and vigour of the discussion which arose. The practical result of it was nevertheless disappointing, owing to want of organisation. The subject is a huge one, and no attempt was made to confine the discussion to definite points, and each speaker dwelt mostly upon matters of special personal interest, instead of directing his efforts to support or combat any distinct issues. The discussion was maintained with undiminished vigour until it had to be concluded from lack of time; but the result of it all was only too truly summarised in the words of the chairman when he stated that, as the subject was now fairly *opened*, he hoped that it would be taken up vigorously by the scientific press throughout the country in order that by *next year* some definite result might be arrived at.

HERMANN VON HELMHOLTZ.*

(Concluded from page 439.)

The problems which v. Helmholtz attacked when he applied delicate physical methods to the investigation of the time relations of muscular contraction and of nervous acts are so full of interest as to merit a passing notice, even in so brief a summary as that we are able to give.

"A moment" is the popular expression for an immeasurably short space of time. v. Helmholtz showed that the muscular contraction which physiologists designate "a simple muscular contraction," and which the non-scientific person would pronounce an instantaneous act, lasts about one-tenth of a second, and is, therefore, more than one thousand times as long as a flash of lightning. "Quick as thought" expresses the popular conception of inconceivable speed. The older physiologists shared the popular idea. Thus we find Johannes Müller stating in the last edition of his text-book (1844, Vol. I., p. 551):—"Stimuli act instantaneously throughout the whole length of the nerves, and throughout all their fibres, irrespective of the point of stimulation." Basing his opinion on the researches of Du Bois Reymond, Johannes Müller inclined to the opinion that nervous force and electricity were identical. As early as 1845, Du Bois Reymond had worked out the plan of estimating the speed of muscular and nervous activity by the method which Pouillet had devised for measuring exceedingly short intervals of time. He, however, had hesitated to carry out this plan, fearing much that this method of research would not be applicable for measuring such great velocities through such short paths. Five years later v. Helmholtz, by means of Pouillet's method, as well as by a graphic method, estimated the mean rate of transmission of nervous activity in the motor nerves of the frog, and found it to be 26·4 metres per second, or less than 10 times slower than the velocity of sound in air, or about equal to the rate of an English express train. In the course of these researches, he enriched physiological experimental methods by his myographion.

In the very next year (1851) v. Helmholtz astounded the scientific world by his discovery and description of the ophthalmoscope, for examining the retina in the living eye, "an optical instrument, by the aid of which it is possible to see exactly, and to recognise, in the living eye, the retina itself and the images of luminous objects thrown on it." By this discovery v. Helmholtz raised ophthalmic medicine to the position of a scientific study, and made it possible to save the eyesight of thousands of human beings. This magnificent discovery, too, was not due to direct inspiration. Already, in 1847, Cuming and Brücke had explained the conditions under which the interior of the eye appears luminous, and a Bernese doctor, von Erlach, had succeeded in illuminating the fundus of the eye by means of his spectacle glasses. But it is just the characteristic of the far seeing intellect of v. Helmholtz that it recognises the importance of things which even men of the calibre of a Du Bois Reymond or a Brücke pass by, with open eyes. In this respect he resembles Theodor Schwann, his celebrated predecessor with Johannes Müller; he surpassed Schwann, however, in his thoroughness, which led him always to test his work, "and not to leave it until it is impossible to improve upon it. It is work of this kind, which, by the classic completeness of its methods, and by the accuracy and reliability of its results, deserves and obtains the best and most lasting fame."*

It was by work of this kind that v. Helmholtz worked out and elaborated physiological optics, in the first instance discovering the nature of the act of accommodation by the employment of new methods, and especially by the use of the ophthalmometer (1853). Afterwards, when Professor of Anatomy and Physiology in Bonn (1855), he investigated the composition and action of the spectral colours. Ten laborious years he devoted, mostly, to his "Text Book of Physiological Optics" (1856-1866). In this work he made it "his duty to test and verify all essential points by his own observations and experiments." Thus, this work has become, as it were, a Bible to both the physiologist and the ophthalmic surgeon.

The great men who at that time, together with v. Helmholtz, laid the foundation of the modern German Physiological School, E. H. Weber, C. Ludwig, E. du Bois Reymond, and Brücke, had obtained for this science an independent position. It had come to be recognised that physiology must be separated from anatomy, and Du Bois Reymond had avowedly claimed for it the proud aim of ultimately merging into physics and chemistry. The new Chair of Physiology in the University of Heidelberg

* Since the first part of this article appeared, the interesting fact has been communicated to us that the mother of Prof. v. Helmholtz was the daughter of a Hanoverian Artillery officer of the name of Penne, a lineal descendant of William Penn, the renowned founder of Pennsylvania.

* These words of praise v. Helmholtz applied to the great physicist Magnus, his predecessor in the Chair which he afterwards filled in the University of Berlin. (Speeches: Vol. II., p. 40.)

was offered to v. Helmholtz, and accepted by him. It was in Heidelberg that he displayed a new aspect of his high genius. He there produced his work entitled "The Doctrine of Tone Sensations as a Physiological Basis of the Theory of Music." "Music," said v. Helmholtz, "stands in a much nearer relation to pure *sensations* than any of the other arts, which have rather to do with *perception*—that is, with the conceptions of external objects—these being the results of psychical processes originating in sensations." Poetry obtains assistance only in a minor degree from music, *e.g.*, in its rhythm, "but tone painting depends directly on the sensory endowment of the ear." "In painting, colour is an element which is directly taken up by sensory perception." "The artistic pleasure given by a marble statue does not arise from the sensation of the white light which it sends into the eye, but rather from the conception of the beautifully formed human body which it represents." "Tones and tone sensations act quite independently of their relation to any external objects."

Pythagoras was well acquainted, from the ancient teachings of the Egyptian priests, that harmony—"the perfect consonance"—is produced when strings whose lengths (material and tension being the same) are in the ratio 1:2, or 2:3, or 3:4 are sounded together. They then sound the octave, fifth, or fourth. Nowadays, measurement is not expressed in terms of the length of strings, but of the number of vibrations, and by this means the laws of harmony can be tested on all musical instruments. To these consonances have been added the major and minor third (4:5 and 5:6). But what has pleasurable sensation to do with simple numerical ratios? Does a foot-rule give us any pleasure? V. Helmholtz had already put forth the fundamental ideas of his theory in popular form in 1857 in a lecture he gave at Bonn "On the Physiological Causes of Musical Harmony." His sequence of ideas was essentially as follows:—The ear separates those wave-forms which flow to it, if not already simple (*e.g.*, the note of a tuning-fork), into a number of simple waves, and feels these separately as simple notes, and does this whether the wave originated as such from the source of sound, or was compounded on the way. It is the grooved basilar membrane in the cochlea, an organ comparable to a harp in structure, which gives the ear the capability of doing this with the greatest accuracy and certainty. If a mixed note hits them, all those string-like portions of the membrane, whose individual parts correspond in vibration number to the single tones in the note are thrown into vibration, just as a number of strings in a piano (with the dampers off) vibrate, if a vowel is spoken into it. Besides the fundamental tone, the overtones are also heard.

The vibrations of two notes, but slightly different in pitch, strengthen and weaken each other periodically; we hear waverings, beats, grating; rough dissonance. In a similar manner, but not so markedly, neighbouring overtones interfere with each other. "Harmony and discord differ in this: in the first the tones flow away easily, each by itself, whilst in discord disturbances occur, and the tones are divided up and collide with each other. "Artistic instinct unconsciously discovers the nature of the artistically beautiful." In a word, v. Helmholtz discovered the hidden law which governs the musical character of harmonic tone combinations. In the course of these researches, he thoroughly traced out the mechanism of the auditory ossicles (1867 and 1869) and enriched philology with the theory of the formation of vowels. He showed that the principal difference between vowel sounds and those of most musical instruments is that the strength of their over-tones depends not only on their serial number, but chiefly on their absolute pitch, and that the various vowels are distinguished by the difference in the strength of their over-tones. By altering the length, width, and form of the cavity of the mouth, the speaker is able to give the strength to the dominant overtones which characterise the vowels he desires to utter.

Besides the physiological researches which have been briefly referred to, v. Helmholtz turned his attention to others closely connected with them. In optics he developed our knowledge of the horopter; in muscle physiology he investigated the muscular sound, and he added to the physiology of nerves by extending the researches which he had made on the rate of transmission of impulses in the nerves of the frog to the motor nerves of man. Moreover, in conjunction with his pupils, he now attacked problems of the highest interest to psychology, problems which had obtruded themselves on his attention in the course of his investigations on light and sound. Thus he measured, by strict physical methods, the time required for the perception of the effects of external stimuli, as well as the time occupied in the simplest mental processes.

The interest which v. Helmholtz manifests in branches of philosophy other than psychology is shown by the scientific scrutiny to which he subjected the axioms of geometry ("Collected Essays," Vol. II., p. 610; "Letters," Vol, II., p. 1). In the course of his researches on the representation in space of the system of colours, as well as on the origin of the power which the eye possesses of estimating magnitude, he had arrived at the conclusion that the axioms of geometry possess no *à priori* significance. As is matter of common knowledge, certain of these axioms assert that—(1) a straight line is the shortest path between two points; (2) a plane can be drawn through any three points in space which do not lie in the same straight line; (3) two lines are termed parallel if lying in the same plane, they never intersect; (4) through a point outside a given straight line but one line can be drawn parallel to the given line. Besides these, geometrical axioms give expression to statements determining the number of dimensions of space, its surfaces, lines, and points, and explanatory of the idea of continuity, *e.g.*, the boundaries of a body are its surfaces, of a surface a line, of a line a point, and a point is indivisible. Further, that by the motion of a point a line is described, by the motion of a line a line or surface, by that of a surface a surface or solid, but by that of a solid only a solid. All this is unproved, and did not seem to need proof as long as the only method of geometry was that of Euclid and his followers ("Lectures," Vol. II., p. 6). But if dimensions of another kind than the Euclidian are imaginable to the mathematical mind, this would be "proof that geometrical axioms are not necessarily conclusions from an *à priori* transcendental form of conception, in Kant's sense of the word" (p. 22). "Every comparison of size, be it estimation or measurement of relations in space, starts from an assumption regarding the physical properties of certain natural bodies, be it of our own forms or of the measuring instruments employed; and, although this assumption is exceedingly probable, and is entirely in concord with all that is known of physical properties, it certainly goes beyond the region of pure conceptions of space." "So that geometrical axioms make assertions, not merely in regard to the properties of space, but also in regard to the mechanical behaviour of the most rigid bodies during motion" (p. 29). "These are facts attained by accumulated experience, like many propositions which have seemed to metaphysicians to be of *à priori* nature. Here, as throughout all his studies, we find v. Helmholtz endeavouring to trace the original cause of phenomena. In the case of the complicated processes of life, with which physiology deals, this is difficult, and generally impossible. It was but natural that the intellectual tendencies of the exact investigator should predispose him to accept the Chair of Physics in the University of Berlin, which had just become vacant by the death of Magnus (1871). From this time forward he was engaged chiefly in inquiries in the great departments of electricity and hydrodynamics, The attempt had been made by celebrated physicists and mathematicians, like W. Weber, Riemann, and Clausius "to explain electrodynamic phenomena by the assumption of forces acting at a distance between two portions of the hypothetical electrical fluid, the intensity being dependent not alone on the distance but also on the velocity and acceleration."* The general mathematical formula of "the law of potential" for the strength of induced currents had been deduced from Ampere's law by the Nestor of Königsberg, F. E. Neumann.

At the time of its discovery, Newton put forth his great law of gravitation, which was to hold together the solar system, with hesitation and diffidence. The idea of forces acting in the absence of intermediate points of action, although then so daring, seems now self evident. Faraday again raised the

discussion on the problem whether forces exist acting at a distance without an intervening medium, by his remarkable discoveries of the phenomena of induction, rotation of the plane of polarisation by magnetisation, dielectric polarisation of insulators, and of diamagnetism. He concluded that every portion of space through which the magnetic force acts is in a permanently altered condition, in a state of tension which tends to return to its original condition as soon as the magnetic influence ceases, and that every alteration in this condition is manifested by the appearance of electromotive forces. Maxwell worked out the new theory mathematically and showed the possibility of regarding electricity, magnetism, and light as merely different states and motions of the same medium (the ether).

The aim of v. Helmholtz in this direction "had been to determine in what direction experiments should be made to decide between the various theories. He succeeded in making such an experiment on the electricity collected on the surface of a conductor rotating in the magnetic field. This experiment decided in Faraday's favour."* The second great problem whose elucidation Faraday had in mind, namely, the relation between electrical and chemical forces, stimulated v. Helmholtz to a series of important investigations. He formulated Faraday's law in this way :—"Through every cross-section of an electrical conductor there is always equivalent electrical and chemical motion" (*loc. cit.* 295). He then investigated this motion and the forces expended on it. He was able by means of the mechanical theory of heat, to calculate (in the case of a solution of salt), the effect of the water on the electromotive force. In this way he came to the investigation of the thermo-dynamics of chemical process and solved the general problem—what portion of the energy present in any system can be transformed into another kind.† He arrived at the result that all chemical compounds below their dissociative temperature give off heat, if produced in the reverse manner." In a highly ingenious manner he showed the reflex effects of the ether and ponderable atoms on each other, in his work on "The Theory of Abnormal Dispersion."‡

Having in 1888 already shown the remarkable analogy of the vortex motions of water with the electro-magnetic effects of electric currents,§ he now applied the theory of friction of solid bodies to that of flowing extremely thin films of fluids, and thus created an analogy between electro-dynamics and hydro-dynamics (1879).‖ He also introduced the conception of "Electrical Convection," viz., "The Transmission of Electricity by the Movement of its Ponderable Conductors" (1876). He showed that the law of constancy of energy makes it possible,¶ without the aid of any hypothesis as to the internal constitution of electrically or magnetically polarised bodies, to find the effect of the pondero-motor forces acting on the interior of such bodies, and causing changes of form. The conclusion is that the hypothetical system, assumed by Faraday, of tensions acting along, and pressure at right angles to, the lines of force, actually exists and acts in such bodies.

In his studies on the statics of mono cyclic systems** he added to mechanics the new idea of "Kinematic connection" (where the kinetic energy is the integrating denominator), *e.g.*, between bodies of the same temperature, or two tops whose axes are so connected that they must preserve the same rate of rotation.

In another essay†† v. Helmholtz thought the "principle of least action" was the general law governing all "reversible natural processes," and as regards the irreversible processes, *e.g*, the production and conduction of heat, it appears that the irreversibility is not intrinsic, but depends more on our limited means of action, since these do not allow us to bring back displaced atomic motions to their initial condition, or to effect the exact reversal of all atoms engaged in thermal motion.

The motion of fluids had already interested v. Helmholtz greatly at the time of his first acoustical investigations. He had investigated theoretically the motions of vortices in 1858, and confirmed the results in a few simple cases by experiment. Dove had shown that the constant change of weather, to which we are subject, was due to reciprocal alterations of cool dry polar winds and warm damp equatorial winds. In a lecture given in 1875* on cyclones and thunderstorms, v. Helmholtz explained the mechanical relations of wind currents, one upon another. Later on, he gave a mathematical investigation of atmospheric movements.† Starting from Euler's hydrodynamical differential equations, he came to the conclusion that the chief resistance to the circulation of the atmosphere lay not solely in its friction against the earth's surface, but rather in the mixing of different moving strata of air, leading to the formation of vortices. At the Cape d'Antibes he made observations on the energy of the waves and wind. The results obtained were that a wind lasting a considerable time gradually gives up some of the energy of its lower layers to the water. Wave systems of different length are thereby formed, and by their interaction (just like the formation of combination tones), stationary waves of greater length and velocity are formed. The wind can give up energy to the waves as long as its velocity is greater than theirs.

Lightning is explained in the above-mentioned lecture somewhat as follows :—The earth is permanently charged with (probably negative) electricity. Air and water vapour (not fog) are electrical non-conductors. Only when the clouds unite to form rain, and thus allow their water masses to come near enough together to allow of discharge from drop to drop, do they form one mighty conductor into which enormous sparks, lightning, can pass from the earth. The rain appears on the earth after the lightning, because it takes so much longer to fall than the time occupied by the electrical discharge. It is not at all impossible that a fire, or the thunder of the cannon in battle, should bring about a storm. If a state of unstable equilibrium already exists in the atmosphere, any circumstance which will cause the first small portion of the damp, warm, mass of air to rise may act the part of a spark in a powder magazine, and direct the chief discharge to the spot of this primary disturbance. We cannot hope ever to be able to forecast the weather. For small primary errors do not produce simply small errors in the results, because the item of unstable equilibrium enters into the conditions.

Though we have only touched but briefly on some of the most important of the researches of our great master, our survey, as yet far from complete, will have convinced the reader that scarcely a region throughout the whole domain of nature has been left altogether unassailed by him ; "wherever he attacks it he is interesting." The capacity to apply theoretical conceptions to practical uses is illustrated by his applying the discussion of a theorem on the geometrically similar movement of fluid bodies to the problem of steering the balloon.‡ That he still preserves a deep interest in the subject of one of the greatest works of his life is shown by his discovering, quite recently, whilst making experiments on his own eyes, that their fundi were themselves luminous, so that he was able to recognise the movement of his own arm in intense darkness.§ In the autumn of 1887 the German Empire founded a physical-technical institution, Dr. Werner Siemens, the well-known electrician, having given for the purpose a sum of one half-million of marks (£25,000). The institute comprises two departments, one for purely scientific purposes, and the other concerned with the application of scientific physics to technical purposes. The first is a laboratory for the advancement of pure science. Such work as may be necessary for the advancement either of science or of technical pursuits, and which requires for its accomplishment specially fitted rooms, costly apparatus, and special talent is to be done there. The second department

has for its object to develop technical-scientific methods and appliances, and to keep industry abreast of the progress of science. Over this great and important new institution, v. Helmholtz was chosen by the Government to preside, whilst he was further appointed director of the first, or purely scientific, department. In consequence, he resigned the Chair of Physics and the directorship of the Physical Institute of Berlin, though he still retains the position of Professor ordinarius in the University, and delivers lectures on special subjects of theoretical physics. In 1883 the German Emperor conferred on Herr Helmholtz and on his family the honour of hereditary nobility.

To give an adequate account of the life and works of v. Helmholtz would require a large volume. The brief notice of those works which we have been enabled to give leads us, however, almost naturally to certain more general reflections concerning his genius, character, and life-work.

One of the first reflections which occurs to one in relation to the scientific work of v. Helmholtz is, that no problem has appeared to him impossible, and, at the same time, he has considered no technical detail insignificant or unimportant. His estimate of the value of popular exposition has been a high one, and he has not thought it beneath himself to lecture and write in a popular style. Even the readers of this sketch have had the opportunity of appreciating, from the quotations which it contains, the clear and beautiful manner in which he can explain difficult problems in mathematics, in physical science, or in philosophy. In connection with these popular expositions a reflection must force itself upon everyone, capable of judging, in reference to one of the highest characteristics of v. Helmholtz as a popular teacher: he does not sink to the level of his audience, but he draws them up towards himself.

But in addition to science, the arts, and Nature also, find a place in his great mind. Of music he is a friend full of understanding and devotion. Already in 1857, in the birthplace of Beethoven (Bonn), he praised the power of music in the following words:—"In an artistic musical work the movement of sound follows the outflow of the artist's own emotions. Now gently gliding, now gracefully leaping, now violently stirred, penetrated, and laboriously contending with the natural expression, the stream of sound, in primitive vivacity, bears, even into the hearer's soul, unimagined moods which the artist had overheard from his own, and finally raising him to that repose of everlasting beauty of which God has allowed but a few of his elect favourites to be the heralds." After leading home, as his wife, to his stately official dwelling, the gifted daughter of the celebrated statesman Robert von Mohl, the hospitality of the honoured couple was exercised in the noblest manner. The evening receptions brought together a great number of the most learned and accomplished men and women of Berlin, and were always rendered charming by the musical talents of the most celebrated artists. As admirers of Wagner, they often made a pilgrimage to Bayreuth during the representations there, and thence the great investigator loved to wend his way to the world of Alpine Nature in the Engadine.

Accurate and close as is his mind in the pursuit of scientific truths, his sensitive nature expands at the sight of the higher regions of Nature. In the introduction to his lecture on "Ice and Glaciers" he says "whilst some content themselves with admiring from afar the dazzling adornment which the pure luminous masses of snowy peaks, interposed between the ocean blue of the sky and the softer green of the meadows, lend to the landscape, others more boldly penetrate into the strange world, willingly subjecting themselves to extreme degrees of exertion and danger, if only they may fill themselves with the aspect of its sublimity."

What a noble revelation of his inner self does he afford us in the toast in honour of the town of Heidelberg, which he proposed on the occasion of the fifth centenary of the foundation of the University of Heidelberg.

He would, he said, consider the beauty of the University town from the standpoint of the man of science. "Was it a mere accident that it was from these green hills that the mental eye of man for the first time penetrated the immeasurable world of space with the idea of how the chemical nature of the heavenly bodies might be deciphered—an undertaking which just before must have appeared an utter impossibility? I think the opposite. Something of a poet's intuition the investigator must have. Naturally, he must have care and patience to sift and prepare his material. But work alone cannot compel luminous ideas; these, like Minerva from the head of Jupiter, spring into being unexpected and unforeseen; we know not whence they come. This only is certain. To him who knows life only from books and paper, and who is tired and exhausted by the monotony of work, to him they come not. The consciousness of fulness of life and power must be present, such as comes from wandering in the pure air of the mountains. And when the wanderer, separated by the quiet peacefulness of the forest from the turmoil of the world, beholds, at one glance, spread before him, the rich plain, with the fields and villages, and the setting sun spinning golden threads over the distant hills, then arise in sympathy, in the dark background of his mind, the germs of new ideas, destined to bring light and power into the inner world of his imagination, where before there was chaos and darkness." Thus this great man, in the festive hours, allows us to catch a glimpse of the workings of his mind. But he who would appreciate the full stature of this ruling mind must climb the lower intellectual heights, and the greater the height he is able to attain the more gigantic will the mountain seem above him. To-day the scientific men of both hemispheres unite to do honour to v. Helmholtz. A gold medal has been struck in his honour, which is to be annually awarded to the most worthy of his co-workers. Let the cultured of all classes hand the laurel crown to one of the noblest of men, cherishing the hope that his exalted intellect may long remain to enlighten us.

HUGO KRONECKER.

ELECTRICAL PAPERS AT THE BRITISH ASSOCIATION.

The following is a complete list of the electrical Papers read, and reports presented, at the recent meeting of the British Association:—

SECTION A.

PROFS. W. E. AYRTON, F.R.S., and A. W. RUCKER, F.R.S.—"On the Magnetic Field near the South London Electrical Railway."

J. BROWN.—"On Clausius' Theory of Electrolytic Conduction, and on some recent Evidence for the Dissociation Theory of Electrolysis."

A. P. CHATTOCK.—"On the Electrification of Needle Points in Air."

PROF. A. GRAY.—"Note on the Electro-magnetic Theory of the Rotation of the Plane of Polarised Light."

PROF. D. E. JONES.—"On the Measurement of Stationary Hertzian Oscillations and the Damping of Electric Waves along Wires."

PROF. J. VIRIAMU JONES and T. HARRISON.—"On the Periodic Time of Tuning Forks Maintained in Vibration Electrically."

J. LARMOR.—"The Character of Electrical Radiation, with a Mechanical Analogy."

J. MILNE, F.R.S.—"On Phenomena which might be Observable if the Hypothesis that Earthquakes are Connected with Electrical Phenomena be Entertained."

R. L. MOND.—"Electrolytic Problems."

W. MOON.—"Absolute Units of Measurement."

W. N. SHAW, F.R.S.—"Report on the present State of our Knowledge in Electrolysis and Electro-chemistry."

G. JOHNSTONE STONEY, F.R.S.—"On the Relations between Electrical Units."

PROF. W. STROUD.—"Some Revolutionary Suggestions on the Nomenclature of Electrical and Mechanical Units."

J. SWINBURNE.—"On the Measurement of Liquid Resistance."

J. SWINBURNE.—"The Causes of Variation of Clark Standard Cells."

W. THORP.—"On the Propagation of Electro-magnetic Waves in Wires."

Digitized by Google

F. T. TROUTON.—"Magnetic Experiments Made in Connection with the Determination of the Rate of Propagation of Magnetisation in Iron."

A. G. WEBSTER, D.Sc.—"On a Method of Determining the Ratio between the Electrostatic and Electro-magnetic Units."

Report of the Committee on Researches in Electro-optics.

Report of the Committee on Electrolysis.

Report of the Committee on the Phenomena accompanying the Discharge of Electricity from Points.

Report of the Committee on the Reduction of Magnetic Observations.

Report of the Committee on Electrical Standards.

SECTION B.

W. CROOKES, F.R.S.—"Electrical Evaporation of Metals and Alloys."

DR. J. H. GLADSTONE, F.R.S., and W. HIBBERT.—"Some Experiments on the Molecular Refraction of Dissolved Electrolytes."

H. C. JENKINS.—"Note on Electrolysis of Alloys."

PROF. ROBERTS-AUSTEN, F.R.S.—"Certain Pyrometric Measurements and Method of recording them."

SECTION G.

A. R. BENNETT.—"The Telephoning of Great Cities."

A. R. BENNETT.—"Orran Electrical Parcel Exchange System."

G. FORBES.—"Recent Progress in the use of Electric Motors."

W. H. PREECE.—"The London and Paris Telephone."
